AMERICAN PUBLISHER'S NOTICE.

THIS work, although based upon Chambers's Encyclopædia, whose distinguished merit is widely known, differs from it in important respects. It could scarcely be expected that an Encyclopædia, edited and published for a foreign market, would give as much prominence to American topics as American readers might desire. To supply these and other deficiencies the American Editors have inserted about 15,000 titles, arranging the whole, including Chambers's Supplement, in a single alphabet. The total number of titles is now about 40,000. The additions give greater fullness in the departments of biography, geography, history, natural history, and general and applied science. Scrupulous care has been taken not to mutilate or modify the original text of the edition of 1880; no changes have been made except such verbal alterations as are required by the omission of the wood-cuts. The titles of articles from Chambers's Encyclopædia, either from the main work or from the Supplement, are printed in bold-faced type—**AMERICA**. The titles of the American additions, whether of new topics or of enlargements of the old, are printed in plain capitals—**AMERICA**. Should it appear that an article from the English work and its American continuation disagree in any points, the reader will readily refer the conflicting statements to their proper sources.

The labor of consultation will be much reduced by the catch-words in bold-faced type at the top of the page, being the first and last titles of the pages which face each other; and by the full title-words on the back of the volume, being the first and last titles contained therein.

The word *ante* refers to Chambers's Encyclopædia, as represented in this issue. Whenever the word (*ante*) follows a title in the American additions, it indicates that the article is an enlargement of one under the same title in Chambers's Encyclopædia—usually to be found immediately preceding.

LIBRARY OF UNIVERSAL KNOWLEDGE.

STRANGULATION may be defined to be "an act of violence in which constriction is applied directly to the neck, either around it or in the fore part, so as to prevent the passage of air, and thereby suddenly suspending respiration and life."—Taylor's *Principles and Practice of Medical Jurisprudence*, 1865, p. 673. This definition, as Dr. Taylor observes, obviously includes hanging (q.v.). *Hanging* has been already briefly noticed in a special article, but the medico-legal relations of this and the other varieties of strangulation have still to be considered. The primary cause of death from hanging has been considered in the article just referred to, but it is necessary to add that if a person who has hanged himself has been cut down sufficiently soon to allow of the respiratory process being restored, he is by no means safe; death often taking place from secondary effects at various periods after the accident. The most prominent morbid appearance in these instances was extreme congestion of the brain.

When the suspension of the body has not continued for much more than five minutes, and the parts about the neck have not suffered violence, there is a probability that resuscitation may be established; although many cases are recorded, when after only a few minutes' suspension, it has been found impossible to restore life. It is believed that death takes place very rapidly, and without causing any suffering; the violent convulsions that are so often observed being similar to those which occur in epilepsy. A man named Hornshaw, who was on three occasions resuscitated from hanging—a feat which he performed in London for the amusement of the public—stated that he lost his senses almost at once; and other persons who have been restored state that the only symptoms of which they were conscious were a ringing in the ears, a flash of light before the eyes, then darkness and oblivion. The treatment to be adopted after the patient has been cut down may be briefly summed up as follows: exposure to a free current of air, cold affusion if the skin is warm, the application of ammonia to the nostrils, of mustard poultices to the chest and legs, and of hot water to the feet, and the subsequent abstraction of blood if there should be much cerebral congestion; artificial respiration should also be tried if the above means fail to re-establish the respiratory process. From the post-mortem appearances, together with circumstantial evidence, the medical practitioner is not unfrequently called upon to decide such questions as these: Was death caused by hanging, or was the body suspended after death? Was the hanging the result of accident, homicide, or suicide? For the full discussion of these questions the reader is referred to chap. 53 of Dr. Taylor's volume. In case of strangulation from other causes than that of hanging, the post-mortem symptoms are similar, but the injury done to the parts about the neck is commonly greater. In manual strangulation, the external marks of injury will be in front of the neck, about and below the larynx; and if death has been caused by a ligature, the mark round the neck will be circular, whereas in hanging it is usually oblique. The internal appearances are much the same as in the case of hanging.

STRANGURY (Gr. *strangx*, that which oozes out, *ourco*, I micturate) is perhaps to be regarded as a symptom rather than a disease. It shows itself in a frequent and irresistible desire to pass water, which is discharged, however, in very small quantity, and whose passage from the bladder is accompanied with scalding and cutting pains along the course of the urethra. The pain often extends to the bladder and even to the kidneys, and is sometimes so severe as to implicate the lower bowel (the rectum), and to produce the straining condition known as *tenesmus*. It is usually caused by irritating substances in the urine, especially by *cantharides* or Spanish flies (whose irritant principle is liable to find its way into the renal secretion, whether the above named drug is taken internally or merely applied to the skin as a blistering agent), and by oil of turpentine, when administered internally in small doses, and is generally present in cases of gravel. Severe as the affection is, it is very transitory, and yields readily to treatment. After the removal of the cause, if it can be recognized and the removal is possible, a dram of laudanum in a wine-glassful of starch mucilage should be thrown into the lower bowel, and mild mucilaginous draughts (of barley-water, for example) should be

freely given in order to render the urine less irritating. The warm bath is also useful, and if it cannot readily be obtained, hot local fomentations often tend to relieve the pain and allow the urine to pass more freely.

STRANRAER, a royal and parliamentary burgh, sea-port, and market-town of Wigtownshire, at the head of loch Ryan, 6 m. n.e. of Portpatrick. There are no manufactures, the town depending almost wholly on the agricultural interest. The oyster fishery in loch Ryan was at one time very productive, but has latterly fallen off greatly. A mail-steamer runs daily between Stranraer and Larne, in Ireland, in connection with the railways on either side. In 1875, 1258 vessels of 202,770 tons, entered and cleared the port. Agricultural produce and cattle, leather, and shoes are exported. Pop. of royal burgh (1871), 3,615; of parliamentary burgh, 5,941. Stranraer unites with the Wigtown burghs in sending a member to parliament.

STRAP, in carpentry, an iron band fixed round two or more timbers, sometimes with branches along each, to hold them all firmly together.

STRASBOURG (Ger. *Strassburg*), a fortified t., formerly the capital of the French department of the Bas Rhin, but, since 1871, capital of the new German province of Alsace-Lorraine, stands at the confluence of the Ill and the Bruche, and not far from the left bank of the Rhine, 89 m. n. of Basel, and 312 m. e. of Paris by rail. The citadel, originally built by Vauban, 1684, was demolished by the Germans during the bombardment of 1870, but in 1873 they began to rebuild it, and this in conjunction with a system of 12 detached forts, being erected at several miles' distance from the walls, will make the position one of great strength. The most celebrated building is the minster, or cathedral, founded in 1015, which is one of the most sublime specimens of Gothic architecture. Of the two western towers, one, that at the s. corner, has not been completed. The other, finished in 1399, rises, according to Baedeker, to a height of 495 ft. above the pavement—14 ft. higher than the original top of the pyramid of Cheops, while the towers of Cologne cathedral are to be 514 ft. high. The minster has a remarkable astronomical clock representing the planetary system. Other notable structures are the Protestant church of St. Thomas, with the tomb of marshal Saxe, and various monuments to distinguished Strasbourg scholars; the *temple Neuf*, or new temple, the synagogue of the Jews, the town-house, the palace of justice, the arsenal, the episcopal palace, and the theater. The university of Strasbourg was the only complete university in France—i.e., the only one which has the full complement of faculties—besides that of Paris. It was founded in 1621, became specially famous in the branches of medicine and philology, went to the ground during the great revolution, and had its place supplied by an *ecole centrale*. In 1803 a Protestant academy was established with 10 chairs, for teaching theology, philology, philosophy, and history. Five years later, Napoleon founded an imperial academy, with faculties of law, medicine, physical science, and philosophy; and in 1819 a partial fusion of these academies took place, greatly to the benefit of both. The university was reopened after the Franco-Prussian war, in May, 1872. In 1878 it had 624 students. The famous library of Strasbourg, consisting of nearly 200,000 volumes, and rich in *incunabula* (q.v.), was entirely destroyed by fire during the bombardment in 1870, but has been to some extent replaced by a library of about 120,000 volumes contributed by the Germans. The trade of Strasbourg, especially its transit-trade, is very extensive, and it has a great variety of manufactures—beer, ham, sausages, fat-liver pies, watches and clocks, leather, cottons, woolens, silks, cutlery, musical and mathematical instruments, jewelry, brandy, potash, tobacco, etc. The Basel and Baden railways, the railway to Paris, and the communication with Rotterdam and London by means of the Rhine steamers, as well as with the Danube and all the great rivers of France by means of canals, have greatly added to its facilities for conducting commerce. The country round about Strasbourg is fertile and carefully cultivated, with beautiful gardens, mansions, and villages. Pop. (71), 85,529; (75), 92,379, of whom about one-half are Catholics.

Strasbourg, the *Argentoratum* of the Romans, was extant before the time of Cæsar, but is first mentioned by Ptolemy. The Romans had a manufactory of arms here. In the 5th c. it appears to have received the name of *Strata-Burgum* or *Strata-Burgus*, perhaps from the invading Franks, whence the modern German Strassburg and the French Strasbourg. It became a free town of the German empire, and in 1681 passed with the rest of Alsace into the hands of the French, under whom its population and prosperity greatly increased. On Sept. 28, 1870, after a bombardment of seven weeks, Strasbourg surrendered to the Germans, and in 1871 was annexed to Germany.

STRATEGY is defined by military writers to be the science of manœuvring an army out of fire of the enemy, as *tactics* is the art of managing it in a battle, or under fire. Strategy is the greater science, as including all those vast combinations which lead to the subsequent available displays of tactics. A good strategist has to attend to the establishing of his bases and depots, although some brilliant generals have dared to act without these last aids—notably, Sherman in America in 1864, and Wellington in 1813, advancing from Portugal through Spain into France. The strategist must know how to diffuse the influence of his arms over a broad area, while yet holding his force well in hand to strike crushing blows. Such was Wellington's Salamanca campaign; in which,

though retreating himself to his former base, he compelled the French to evacuate Valentia.

Strategy must not be confounded with stratagem, although there is relationship between the two. Stratagem is any device for deceiving the enemy as to the point or strength of an attack. Such are ambuscades, feints, bugle-calls to imaginary troops, concealment of infantry by clouds of cavalry, and many other efforts.

STRATFORD, a thriving t. of Essex, on the Lea, 3 m. e. of London. It is the seat of various and extensive manufactures. There are flour-mills, distilleries, and chemical works. In the town and its suburbs, many London merchants have built residences. The prosperity of the town has been much increased by its connection with the Eastern Counties railway. Pop. '51, 10,586; '61, 15,994; '71, 23,286. On the opposite side of the Lea is the parish of Stratford-le-Bow, or Bow, with (1871) 26,055 inhabitants.

STRATFORD, a t. in s.w. Ontario; co. seat of Perth co., and port of entry; at the junction of the Buffalo and Goderich division with the main line of the Grand Trunk railway; pop. '71, 4,313. It is 88 m. from Toronto, has valuable water-power, and is the center of a fertile agricultural region. It contains the court-house and county offices, a town-hall, 7 churches, 3 newspapers (1 German), a monthly magazine, 3 branch banks, and several hotels. The leading industries are the manufacture of ale and beer, flour, iron castings, machinery, agricultural implements, wooden goods, steam-engines, and boilers, leather, boots and shoes. It contains the railroad repair shops.

STRATFORD-DE-REDCLIFFE, **STRATFORD CANNING**, Viscount, English diplomatist, is son of a London merchant, and cousin of the celebrated George Canning. He was born 1788, educated at Eton, and entered himself of King's college, Cambridge, in 1806, but left in 1807, on receiving an appointment as *premier* writer in the foreign office. He was appointed secretary of embassy at Constantinople in 1809. He returned to Cambridge in 1812 for the purpose of resuming his studies, and took the degree of M.A. He was sent as envoy to Switzerland in 1814. About this time he published an ode full of spirit and power, entitled *Bonaparte*. It is called by Lord Byron a "noble poem." In 1820 he went as plenipotentiary to the United States, and remained at Washington three years. In 1824 he was sent on special missions to St. Petersburg and Vienna. In 1825 his introduction to eastern diplomacy commenced with his appointment by Mr. Canning, then foreign secretary, as ambassador-extraordinary to the sublime porte. Here his good offices were warmly exerted on behalf of the Greeks. In 1831 he was accredited with a special mission to Turkey, to fix the boundaries of the new kingdom of Greece, and to settle the treaty in virtue of which Otto ascended the Greek throne. He went to Madrid and Lisbon on a special mission in 1832. He had previously sat in the house of commons for Old Sarum and Stockbridge during a brief interval in his diplomatic career. In 1834 he was elected for King's Lynn, which he represented until 1841, when, having twice refused the governor-generalship of Canada, he was appointed by the government of Sir Robert Peel ambassador at Constantinople. Here his influence was strenuously exerted in the cause of civilization and progress. In 1852 the Derby administration recommended the crown to confer upon him the title and dignity of viscount. When the long-standing quarrel between the Greek and Latin monks in Palestine involved the powers of Europe in the struggle, Stratford remembered how the emperor Nicholas of Russia had, from 1829 to 1853, sought to establish a predominant influence, excluding all others, over the porte, with the view of settling the future destinies of Turkey to the profit of Russia when the propitious juncture arrived. At the time when prince Menchikoff was sent to Constantinople upon a mission from the czar, Stratford was absent in England on leave. He returned to Constantinople in April, 1853, and prepared to resist Menchikoff's demands. The keenly contested diplomatic struggle between Stratford and the Russian ambassador extraordinary is narrated with dramatic power by Mr. Kinglake in his *Invasion of the Crimea*, who calls Stratford the "Great Elteli." Stratford's influence with the porte prevailed, for, to adopt the words of Mr. Kinglake, "as though yielding to fate itself, the Turkish mind used to bend and fall down before him;" and he placed on England the responsibility of a defensive alliance with the sultan against the czar. As Russia would not withdraw her troops from the principalities, the sultan declared war against Russia, and France and England came to the aid of the porte. Stratford retired from the Turkish embassy in 1858 upon a pension. He has since taken a frequent part in the debates of the upper house on questions of foreign policy. He was created a knight of the garter in 1869. In 1873 he published *Why am I a Christian?* a work on the evidences of Christianity, and in 1876 a play, *Alfred the Great in Athelney*.

STRATFORD-DE-REDCLIFFE, **STRATFORD CANNING**, Viscount (*ante*). Believing that the independence of Turkey with equal rights to all races and religionists would best promote the peace of Europe and the prosperity of the numerous nationalities embraced under Turkish rule, he labored assiduously to promote these objects. For 14 years he not only ruled the empire of Turkey by his personal influence with the sultan Mahmoud, whose throne had just been saved by the intervention of Europe against Mohammed Ali, but also swayed the policy of Europe in regard to the east.

The hattı-houmayoun, which promised so much for civil and religious liberty in Turkey, was his work; and had he continued to represent England in Constantinople, it probably would not have remained a dead letter. He however was withdrawn to please Napoleon, who sought to make French influence predominant in the east. He was an earnest Christian; warmly appreciated the work of the American missionaries in Turkey, and aided them by counsel and influence. He protected the persecuted, founded the Protestant civil community in Turkey, and secured to them whatever privileges they enjoy. He died Aug. 14, 1880.

STRATFORD-UPON-AVON, a municipal borough and township of England, in the county of Warwick, and 8 m. s.w. of the town of that name, is situated on the right bank of the river Avon. Pop. '71, 3,863. The town is neatly built, and has quite a modern look, most of the old houses having disappeared. Some trade is carried on in corn and malt. Stratford-upon-Avon is the birthplace of Shakespeare. The house in which he was born is still preserved, and is visited by enthusiastic pilgrims from all quarters of the world. The great poet is buried in the parish church.

STRATH, a Gaelic word signifying a broad valley, is often prefixed in the n. of Scotland to the names of rivers, as Strathearn, Strathallan, Strathairn, Strathspey, in each of which cases it signifies the open valley through which the river flows. In such cases, however, as Strathmore (great valley), it simply signifies a valley-like depression. In the s. of Scotland, the word is not used, the Northumbrian word *dale* being used instead, as Clydesdale, Annandale, Teviotdale, Tweeddale.

STRATHAVEN, a t. of Scotland, in Lanarkshire, about a mile w. of Avon Water, and 14 m. s.e. of Glasgow. On the n. side is the picturesque ruin of Avondale castle, and from 5 to 7 m. s.w. are the battle-fields of Drumclog and Loudoun Hill. The more recently built part of the town is neat and spacious. Pop. '71, 3,645, chiefly engaged in weaving and trading in cheese and cattle.

STRATHCLYDE. In the 8th c., the ancient confederacy of the Britains was broken up into the separate divisions of Wales and English and Scottish Cumbria. Scottish Cumbria, otherwise called Strathclyde, thenceforth formed a little kingdom, comprising the country between Clyde and Solway, governed by princes of its own, and having the fortress-town of Alelyde or Dumbarton for its capital. Becoming gradually more and more dependent on Scotland, it was annexed to the Scottish crown at the death of Malcolm I., on failure of the line of native sovereigns. Edgar bequeathed Strathclyde to his youngest brother David, again separating it from the crown of Scotland, which went to his intermediate brother, Alexander I. David held it throughout Alexander's reign in spite of that king's opposition, and on Alexander's death without issue in 1124, it was permanently reunited to the Scottish kingdom under David I.

STRATHMORE (the Great Valley), the most extensive plain in Scotland, is a low-lying tract extending across the country from Dumbartonshire n.e. to Stonehaven in Kincardineshire, is bounded on the n. by the great mountain-rampart of the Highlands, and on the s. by the Lennox, the Ochil, and the Sidlaw hills, and is 100 m. long and from 5 to 10 m. broad. In a stricter sense, however, Strathmore proper extends only from the neighborhood of Perth to that of Breechin in Forfar, a distance of about 40 miles.

STRATHSPEY, a kind of Scottish national dance slower than the reel, which is said to derive its name from having been first practiced in the district called Strathspey.

STRATIO TÉS, a genus of plants of the natural order *hydrocharidaceæ*, having a two-leaved spathe with numerous barren flowers, one female flower in each spathe. *S. aloides*, popularly called **WATER SOLDIER**, is common in lakes and ditches in the e. of England. It is a singular plant with numerous leaves, which are strap-shaped, and spring from the root, from which also springs the two-edged flower-stem, bearing the spathe with beautiful and delicate white flowers. In autumn the whole plant disappears, the root alone remaining at the bottom of the water, from which a number of young plants arise in spring, filling up ditches, so that nothing else can grow in them. It is a very ornamental aquatic plant.

STRATUM, pl. *strata* (Lat. strewn or spread out), the term applied by geologists to the layers into which most of the rocks that form the crust of the earth are divided. It implies that the layers have been spread out over the surface, and that they were formed in this way we may infer from the deposits that are now taking place in lakes and seas into which rivers laden with muddy sediment empty themselves.

All the aqueous rocks, which cover so large a proportion of the earth's surface, are stratified. They were formed from the abraded materials of older rocks (aqueous or igneous), which have been washed down and rearranged. The kind of rock produced depended upon the material to which the carrying agent had access. Fine mud would produce shales, sand sandstones, and calcareous matter limestones. In a section, these different kinds of rocks are frequently found to interchange within a short space. This is produced either by the water obtaining different materials, or changing its velocity. Thus the fine sediment which has fallen from slowly flowing water may be covered by a layer of sand brought down by a flood, and this again may have spread over it a covering of shells and corals, and such changes may go on alternately for an

indefinite period. Each of the different beds composed of the same kind of material is called a stratum. Thus, in the series mentioned, there would be a "stratum" of clay, one of sand, and then one of calcareous matter. An assemblage of strata having a common age is called a "formation," and this term is also extended to rocks which agree in their composition or origin. Thus, we speak of stratified and unstratified, aqueous and igneous, fresh water and marine, primary and secondary, metalliferous and non-metalliferous formations. As a formation is composed of many different beds, so a stratum is frequently made up of several "laminae" or "layers." The laminae have a more or less firm cohesion, but the strata easily separate from each other. Sometimes the cohesion of the laminae is so great that it is as easy to split the rock against as with the grain. In such compact rocks the lamination is obscure, or altogether imperceptible in fresh specimens, but whenever they are exposed to the influence of the weather, it becomes obvious. The laminae have been produced by short interruptions in the deposition, similar to what might be the result of tidal or other intermittent action. The degree of cohesion may be the result of rapid succession in the acts of deposition, but it is frequently produced by metamorphic action subsequent to deposition. The planes of stratification want the complete coalescence characteristic of lamination; when the contiguous layers are closely united, it is the result of the adhesion of two bodies, and not of their coalescence into one.

STRAUBING, a t. of Lower Bavaria, on the right bank of the Danube, 25 m. s.e. of Ratisbon, lies in a very fertile valley, and carries on a river-trade in corn, cattle, and horses. In a little chapel here there is a monument to Agnes Bernauer (q.v.). Pop. '75, 11,590.

STRAUSS, DAVID FRIEDRICH, author of the famous *Leben Jesu*, was b. on Jan. 27, 1808, at Ludwigsburg, in Würtemberg. His education was begun in his native town, and completed in the theological seminaries of Blaubeuren and Tübingen. In 1830, his head filled with Hegel's philosophy and Schleiermacher's theology, he entered on the simple life of a country pastor, but already in the following year he was in Maulbronn acting as professor in the seminary, and went thence to Berlin for six months to continue his Hegelian studies, and hear the lectures of Schleiermacher. Returning to Tübingen in 1832, he became *repetent* in the theological seminary, and in the next years held also philosophical lectures in the university as a disciple of Hegel. Known as yet only to a narrow circle, he became all at once a man of mark by the publication, in 1835, of his *Life of Jesus critically treated* (2 vols. Tüb.; 4th ed. 1840; translated into English, 1846). In this work, written from the point of view of a Hegelian philosopher, and designed only for the learned, he attempted to prove the received gospel history to be a collection of myths gradually formed in the early Christian communities, and, sought by an analytical dissection of each separate narrative, to detect, where it existed, a nucleus of historical truth free from every trace of supernaturalism. The book made a real epoch in theological literature, and produced a violent excitement in and out of Germany, calling forth numberless replies from opponents, frightening many by its bold disregard of consequences back into the ranks of orthodoxy, and stirring up others to similar investigations. The first consequence to the author was his dismissal from his academical position in Tübingen, and transference to the gymnasium of Ludwigsburg. He resigned the new post, however, very soon in 1836, and retired into private life at Stuttgart, to have leisure to defend himself. In 1837 he published his *Streitschriften* against his opponents; and in 1838 *Zwei friedliche Blätter*, a more conciliatory exposition of his views. Early in 1839 he was called by the board of education in Zürich to be professor of dogmatics and church history in the university; but the step raised such a storm of opposition among the public that the proposition had to be dropped, and even the government itself had to resign in the same year. Thrown back on his literary labors, Strauss, who had published during the year his *Charakteristiken und Kritiken*, sent forth shortly afterward his second great work, *Die Christliche Glaubenslehre*, a review of Christian dogma "in its historical development and its struggle with modern science" (Tüb. 1840-41). This formed a natural sequel to the purely critical investigation of the origins of Christianity in the first work. When Strauss, after a long period of silence, next appeared on the literary field, it was no longer as a professed theologian. In 1847 he drew attention by a work entitled, *Der Romantiker auf dem Throne der Cäsaren, oder Julian der Atrännyge*, full of direct allusions to the political situation of the day. His fellow-townsmen put him forward as a candidate for the German revolutionary parliament of 1848, but he was unable to stand against the clerical influence brought to bear upon the country-people of the district. His speeches on this occasion were published under the title of *Sein Theologico-political Popular Addresses*, and his native place compensated the defeat by sending him as its representative to the Württemberg diet. From this position, however, when he unexpectedly displayed conservative leanings, and incurred a vote of censure from his constituents, he retired before the end of the year. A life of the Swabian poet Schubart (1849), and another biographical work, *Christian Märklin, a Picture of Life and Character from the Present* (1851), giving an insight into his own mental development, were his next literary efforts, before another period of silence. His third period of activity was opened in 1858 by a remarkable life of the reformer, Ulrich von Hutten (Eng. trans. 1874), followed up by the publica-

tion of Hutten's *Dialogues* in 1860. These books, though primarily of strictly historical interest, were nevertheless calculated for the present state of religious affairs in Germany, and contained fiercely contemptuous denunciations of the tactics of the reactionary party in the church. A collection of miscellaneous *Minor Writings* appeared in 1862, and a new *Life of Jesus, composed for the German people*, in 1864 (Eng. trans. 1865). The title of the work indicates its popular cast, the peculiar features of it being a long critical statement of the labors of others in the same field down to the present day, and an attempt to construct a life out of all the positive results that have been gained. The mythical hypothesis is retained, but applied differently. Still later publications which appeared in 1865 are *Der Christus des Glaubens u. der Jesus der Geschichte* (Berlin), a criticism of the newly published lectures of Schleiermacher on the life of Jesus, and a brochure, *Die Halben u. die Ganzen*, directed against Schenkel and Hengstenberg. The polemic against Schenkel, professor of theology in Heidelberg, a leader of the liberal party in the church of Baden, and author of the *Charakterbild Jesu* (1864), arose out of an earlier notice of this book by Strauss. In 1872 he published his last work, *Der alte und der neue Glaube*, in which he endeavors to prove that Christianity as a system of religious belief is practically dead, and that a new faith must be built up out of a scientific knowledge of nature. Strauss died in 1874. An edition of his collated works (*Gesammelte Schriften*) began to be published in 1876. The literary, critical, and polemical powers of Strauss must be pronounced to be of the highest order. No more effective German prose than his has been written since Lessing.—See *Life of Strauss*, by E. Zeller (Eng. trans. 1874).

STRAUSS, JOHANN, 1804-49, b. Vienna; was a member of Lanner's orchestra, and then gave concerts with a band he organized in the principal cities of Germany. His three sons have become known as composers of dance music. The eldest son, JOHANN, b. 1825, is music director at Vienna to the emperor of Austria. He organized a band which played with great success in all the large European cities. In 1872 he came to the United States to conduct an orchestra of 1000 performers in his own compositions at the Boston peace jubilee. He composed, besides his well-known waltzes, four operettas: *Indigo* (1871), *Der Carnival in Rom* (1873), *Die Fledermaus* (1874), and *Cagliostro* (1875). The second son, JOSEF, 1827-70, b. Vienna, composed about 300 pieces of dance music.—EDUARD, the youngest son, is the leader of an orchestra in Vienna, and has composed about 200 pieces. Together the four Strausses have published over 1100 compositions, of which those of the younger Johann have become the most popular.

STRAWBERRY, *Fragaria*, a genus of plants of the natural order *rosacea*, suborder *roseæ*, tribe *potentillidæ*, remarkable for the manner in which the receptacle increases and becomes succulent, so as to form what is popularly called the fruit; the proper fruit (botanically) being the small *achænia* which it bears upon its surface. The genus differs from *potentilla* (q.v.) chiefly in having the receptacle succulent. The calyx is 10-cleft, the segments alternately smaller; the petals are five; the style springs from near the base of the carpel. All the species are perennial herbaceous plants, throwing out runners to form new plants; and the leaves are generally on long stalks, with three leaflets, deeply toothed. One South American species has simple leaves. Only one species, the WOOD STRAWBERRY, (*F. vesca*), is truly a native of Britain. It is common in woods and thickets. Its fruit is small, but of delicious flavor. Another species, the HARTWIG'S STRAWBERRY (*F. elatior*), is not unfrequently to be seen in woods and hedges, but has probably escaped from gardens. It is really a native of North America. The many kinds cultivated in gardens are regarded as varieties of these species, and of the CAROLINA STRAWBERRY (*F. Caroliniana*), the PINE STRAWBERRY (*F. grandiflora*, or *F. ananas*), and the CHILI STRAWBERRY (*F. Chilensis*), American species, the leaves and fruit of which are larger than those of the wood strawberry. In no genus, however, are the species more uncertain to which the cultivated kinds are to be referred. Some of these are remarkable for the large size of the fruit. New varieties are continually coming into notice, and the utmost care is necessary to keep the larger and finer varieties from degenerating. The cultivation of the strawberry is most extensively carried on in Britain and in Belgium. New kinds are produced from seed; but plantations of strawberries are generally formed of the young plants, which are abundantly produced by runners. The rows are from 18 in. to two ft. apart, according to the kind. The finest fruit is said to be produced when the plants are kept distinct from each other in the rows, but this is not generally done. Tiles are sometimes placed around the plants and under the fruit; and it is an old English practice to lay straw between the rows, to preserve the fruit from rotting on the wet ground, from which the name strawberry has been supposed to be derived; although more probably it is from the wandering habit of the plant, *straw* being a corruption of the Anglo-Saxon *stræ*, from which we have the English verb *stray*. Strawberry beds require to be renewed after a few years. Strawberries are often forced in hot-houses, in order to produce the fruit at a very early season. The uses of the strawberry as a dessert fruit and for preserves are well-known. There is no more wholesome fruit.

The ALPINE STRAWBERRY (*F. collina*), a native of Switzerland and Germany, differs considerably from the other kinds in its taller stems and more erect manner of growth.

The fruit, which is either red or white, is not very large, but is produced in great abundance, and unlike other strawberries, parts from its calyx almost on being touched. The Alpine strawberry continues to produce fruit long after the other kinds.

The INDIAN STRAWBERRY (*F. Indica*), a native of the Himalaya, requires only a little protection in Britain from severe frost, and with this care grows luxuriantly and produces fruit in abundance. The flowers are yellow, not white, as in other strawberries, and are not produced upon common flower-stalks rising from the center of the plant as in the other species, but upon single-flowered stalks, which spring from the axils of the leaves upon the runners. The fruit is very beautiful, growing with its apex upward. It is not, however, of good quality.

STRAW-MANUFACTURES. The industrial applications of the straw of wheat are of great commercial importance, especially that of plaiting, which is one of the oldest arts practiced by mankind, many specimens having been found in the tombs of the ancient Egyptians, and mention being made of plaiting by Herodotus and other early writers. The earliest notice we have of its systematic use in Europe as an article of clothing is in the records of the reign of Mary, queen of Scots, who, we are told, observed that the peasants of Lorraine wore hats made of straw plait, and that this manufacture was beneficial to them, and she consequently conceived the idea of introducing it into Scotland, which was done about the year 1562, but without much success. Her son, James I., however, carried it into England, where it soon thrived, and has been from that time a permanent branch of industry. It was first regularly established in Bedfordshire, which has ever since been the chief seat of the trade.

At first, the plait was what is called *whole straw*; that is, the straw was cut into suitable lengths without knots, and merely pressed flat during the operation of plaiting, and so it continued until the reign of George I., when it was in great demand for ladies' hats, and some plait was made of split straw. Since that time, this kind has been chiefly used, and a much improved method has been substituted for the clumsy one of using a common knife for splitting it. The instrument now employed is made of steel, and consists of a number of little square blades set in a circular manner around a stem, which at one end terminates in a point, and at the other is bent and fixed into a handle. The point being inserted into the hollow of the straw, is pressed forward, and cuts it into as many strips as there are blades in the cutting-tool; these vary in number according to the fineness of the work to be produced.

It is found that the fine straw-plaiting, which is now produced better in England than in any other country except Italy, can only be made from one or two varieties of wheat, that called the White Chittim being generally preferred, and next to it the Red Lammas, which only succeed as a straw-crop upon the light rich soils of the more southern of the midland counties. The harvesting is a matter of great anxiety, as the straw is liable to many injuries from wet and other causes. The value of this crop can be best understood by the fact that an acre will yield from 25 to 40 bushels of wheat, and from 15 cwt. to a ton of straw, which, when in good condition, is worth £7 or £8.

The crop is bought up by straw-factors, who employ people to draw the straw, and remove the ears, which are all cut off by hand for threshing. The straws are afterward cut into lengths and cleared of the outer sheath or leaf; they are then sorted into various thicknesses by an apparatus consisting of a series of sieves about eight inches in diameter; the boys who usually do this work hold a handful on end over the first sieve, which has the narrowest spaces, and the thinnest straws only fall through it; they are next placed on the second, and so on to the last. As they fall through each successive sieve, they pass down through hollow shafts, through shoots of tin or sheet-zinc into boxes, from which they are removed and tied into bundles ready for the splitters, who next take them in hand and reduce them to strips of the sizes required.

The plaits are made by women and children in their own cottages, and are collected by the dealers and sold in the Luton and Dunstable markets, in which the chief part of this business is transacted. They are very various in pattern, and are sold by the *score* of 20 yards, the prices ranging from 2d. to 3s. per score for the ordinary kinds, but very fine plaits have been known to fetch as high as £3 to £4 per score.

It is computed that 70,000 persons are employed in this trade, of whom nearly 60,000 are females and boys, and that they produce annually about 12,000,000 scores, or 240,000,000 yards of plait. The plait is made up into bonnets and hats chiefly at Luton and Dunstable, and sent up to the London warehouses for sale, whence they are sent to all parts of the world. A large trade is also done in the fine plaits of Tuscany; the Leghorn plaits are very fine, and fetch high prices.

Besides its value for plaiting, straw is now much used in the manufacture of paper (q.v.).

STRAW MANUFACTURES (*ante*). From a very early period in the colonial times, the plaiting of straw and its manufacture into suitable goods for domestic use was a common home industry in many New England and other northern households. As these goods were necessarily crude and ungraceful, the wants of the wealthier classes were usually supplied by importation from abroad—principally from Italy. In the early part of this century, however, when the protracted European wars cut off communication with Italy, more attention began to be paid to this branch of industry, and

various manufactories were started which supplied a limited and local trade. But it was not until 1825-30 that the business grew to any real importance or covered any great extent of territory. About that time some of the more enterprising New York and Massachusetts houses sought to develop their facilities so as to reach those portions of the country where straw goods were little known, and the business soon assumed immense proportions. For many years goods were made largely from the straw raised and plaited in this country—the plaiting being done chiefly by females during the intervals of household work—but the cheapness and superiority of foreign braids, in some cases, again drove this form of American labor out of the market. The chief domestic braids now left are the “Mackinaw” straw, which is raised and plaited in Canada and in a few localities in the north-western states, and the palm-leaf, grown in Cuba and split and braided in New England. More than 50 per cent of all the straw goods manufactured in this country are made from the Canton straw imported from China. The Luton straw from England, and the Leghorn from Italy, are also largely used, and small quantities of other varieties are imported from Switzerland, Bohemia, France, Malaga (Spain), Manila, and Central and South America. The total value of the importations is estimated at about \$2,000,000 annually. Straw hats and bonnets are sewn chiefly by the Knowlton and Bosworth sewing machines, which are run by steam and which can turn out as many as 100 hats each in a day. These machines are of American invention and their use is gradually extending abroad. The goods are pressed and blocked into shape at the rate of four a minute, by another machine of American origin. The total value of the straw goods manufactured in the United States, was, in 1860, \$4,395,616, and in 1870, \$7,282,086. The increase in the last ten years has been even more rapid, but the official figures have not yet been published. More than one-half of the entire amount of American straw goods are manufactured in Massachusetts alone, the census of 1870 valuing the products of that state at \$4,869,514, the remainder being divided among the following eight states: Connecticut, \$1,026,000; New York, \$1,006,000; Pennsylvania, \$189,242; California, \$60,700; New Jersey, \$54,530; Rhode Island, \$40,000; Wisconsin, \$34,500; Vermont, \$1,600.

STRAZNICKY, EDWARD R., PH.D., 1820-76; b. Moravia; graduated at a university in Vienna, where he became an expert linguist, and took the degrees of M.D. and PH.D. He was made intendant of an estate belonging to a wealthy Austrian nobleman, but, becoming involved in the struggle of Hungary for liberty, was compelled to leave his country, notwithstanding the fact that one of his near relatives was a field-marshal in the Austrian service. He arrived in New York penniless, and was forced to submit to severe privations during his first years in America. His ability and education, however, at length secured him influential friends, and he was made secretary of the American geographical society, and in 1859 second assistant librarian in the Astor library. He rose through the different grades until, on the retirement of hon. Francis Schroeder, superintendent of the library, he was appointed to that position, which he held until his death.

STREET, ALFRED BILLINGS, 1811-81; b. N. Y.; studied law and practiced a few years at Monticello, N. Y., but after 1838 lived at Albany. He wrote many poems of considerable merit, some of which have been translated into the German. Among his writings were: *The Burning of Schenectady*, and *other Poems* (1842), and *Frontenac, a Tale of the Iroquois in 1696* (1849). In prose, he wrote biographical and historical sketches, *Forest Pictures in the Adirondacks* and *The Indian Pass* (1869). He was for many years state librarian.

STREET, AUGUSTUS RUSSELL, 1791-1866; b. New Haven, Conn.; graduate of Yale college, 1812; studied law; inherited a large estate; gave \$300,000 to Yale college, founding the Street professorship of modern languages. He erected, and partially endowed, the Yale school of fine arts, and left a sum of money to establish the Titus Street professorship. He lived in Europe, 1845-48; returned to this country and died in New Haven. His daughter married admiral Foote.

STREET, GEORGE EDMUND, b. England, 1824; educated at the collegiate school, Camberwell, and afterward studied architecture under G. G. Scott. Among his works are the theological college at Cuddesden, and the churches of St. Philip and James, at Oxford, and of St. Margaret, at Liverpool. Among his restorations are Jesus college chapel, Oxford; and Wantage church. Most of his works are in the Gothic style, upon which he has written much. Among his writings are *The Brick and Marble Architecture of North Italy in the Middle Ages* (1855), and *Gothic Architecture in Spain* (1865).

STRELITZ, more properly *streltzi* (arquebusiers), the ancient Russian militia-guard, first raised by Ivan Vassilevitch the terrible, in the second half of the 16th century. At that time, and for long afterward, they were the only standing army in Russia, and at times amounted to between 40,000 and 50,000 men. They were located at Moscow in time of peace, in a quarter of the capital which was set apart for them, and, being the bravest and most trustworthy troops in the army, were made objects of special favor and distinctions. But like all such petted corps, the Roman pretorians, the Turkish janizaries, and the Egyptian memluks, their general turbulence, frequent revolts against the government (notably during the Demetrian insurrections), and incessant conspiracies

rendered them more formidable to the Russian government than to external enemies. The strelitz having, at the instigation of the grand-duchess Sophia and the chiefs of the Old Muscovite party, revolted against Peter the great, that iron-handed ruler caused them to be decimated (1698) in the great square of Moscow, and the remainder to be banished to Astrakhan. The feeble remnant still manifesting their characteristic turbulence and disloyalty, Peter exterminated them almost completely in 1705. Few Russian families at present can claim kindred with the old streltzi, but to this the family of Orloff (q.v.) forms a prominent exception, being descended from a strelitz who was pardoned by Peter the great while the axe was being raised over him.

STRENGTH OF MATERIALS. The strength of materials depends upon their physical constitution—viz., their form, texture, hardness, elasticity, and ductility.

The resistance of materials in engineering works is tested in reference to various strains; such are—1. Extension or tension; 2. Compression or crushing; 3. Transverse or cross strain; 4. Shearing strain; 5. Torsion or twisting strain.

1. *Extension.*—When a rod is suspended vertically, and a weight attached to its end tending to tear it asunder, all its fibers act equally, and its strength evidently depends on the strength of the individual fibers and their number, that is, the area of cross-section of the rod. The following table gives the resistance to *rupture* of some of the most common materials:

	Per Square Inch.
Fine sandstone.....	200 lbs.
Brick.....	300 “
Common lime.....	50 “
Portland cement.....	240 “
Deal (timber).....	5 tons.
Cast iron (ordinary).....	6½ “
“ Stirling's toughened.....	12½ “
Wrought iron, boiler-plate.....	20 to 24 “
“ bars.....	25 “
Cast steel.....	60 “
Ropes (hemp), four-fifths ton per pound weight per fathom.	

With regard to the elongation of materials under tensional strain, it has been observed that up to a certain limit, which is different for different substances, the elongation is proportional to the extending force, a physical truth the promulgation of which is due to Hooke (q.v.); up to this limit also the body nearly recovers its original form on the removal of the force: this limit is called the limit of elasticity. When this limit is passed, the permanent elongation or destruction rapidly increases until rupture takes place.

The extension of wrought iron is about $\frac{1}{100000}$ of its length per ton of strain per square inch, and that of cast iron $\frac{1}{30000}$. The limit of elasticity of wrought iron is attained under a strain of 12 tons per square inch; and in the case of American pine $1\frac{1}{2}$ ton per square inch.

2. *Compression or Crushing Strain.*—The strength of pieces of stone, wood, or iron, whose height is small in proportion to their area, and which absolutely crush under the strain, is proportional to the area of their horizontal section. The following table gives the resistance to crushing of some of the more common materials:

Cast iron.....	50 tons per square inch.
Wrought iron.....	16 “ “ “
Brickwork.....	30 tons per square foot.
Sandstone.....	200 “ “ “
Limestone.....	490 “ “ “
Deal.....	450 “ “ “
Oak.....	650 “ “ “

Up to a certain strain, which is called the limit of elasticity, the diminutions in length of the body are proportional to the compressing force; and are practically the same in amount as the elongations in the case of tensional forces. In the case of wrought iron, the limit is 12 tons per sq. in.; after that strain, its shape and proportions become permanently altered; and where these are of consequence, as in most practical cases, we come to the limit of its utility, which is reached when the load is about 16 tons per sq. inch. It then oozes away beneath additional strain, as a lump of lead would do in a vise.

The mode of ultimate failure of cast iron is quite distinct from that of wrought iron. It crushes suddenly by the sliding off of the corners in wedge-shaped fragments, being a crystalline mass, without sufficient ductility to allow of its bulging horizontally; the angle of rupture at which these wedges slide off being tolerably constant, and varying from 48° to 58°. The limit of elasticity is attained in cubes of deal under a compression of 100 tons per sq. ft.; and in those of oak, 150 tons per sq. foot.

Pillars, round or square, may be divided into three classes—1. Those whose height is not more than 5 times their diameter; 2. Those whose height is between 5 and 25 times their diameter; 3. Those whose height is at least 25 times their diameter. The

first follow the same laws as cubes or pieces of small height above discussed, and are absolutely crushed; their strength being proportional to their cross section. The second are broken across, partly by crushing and partly by bending. The third give way purely from bending as with a transverse strain, and their strength is found by experiment to be directly proportional to the fourth power of their diameter, and inversely proportional to the square of their length. Thus, in the case of two long pillars of equal length, but of which one has its diameter double that of the other, the strength of the former will be 16 times that of the latter; from which will be apparent the advantage of the tubular form for pillars, as it gives a large diameter, combined with lightness.

In the case of long columns whose length is 25 or more times their diameter, if we represent the strength of a long cast-iron column of any dimensions by 1000, the strength of a wrought iron column of the same dimensions will be 1750; of cast steel, 2,500; of Danzig oak, 110; of red deal, 80.

3. *Transverse or Cross Strain.*—When a beam fixed at one end is loaded with a weight at the other, it is bent from its original form, and takes a curved shape. The fibers on the upper or convex side of the beam are extended, and those on the under or concave compressed; while at the middle of the beam, there are fibers which are neither extended nor compressed, where the compression ends and the extension begins: this surface of fibers is called the neutral surface. As long as the beam is not strained beyond the limit of its elasticity, the extensions and compressions for a given strain are nearly equal, and therefore the neutral surface passes through the center of gravity of the cross section of the beam.

If we strain the beam beyond this limit, and approach the breaking strain, the extensions and compressions are no longer equal, and therefore the position of the neutral surface is not readily determined. For example, in the cases of stone and cast-iron, the amount of compression is much less than that of the extension, and in the case of timber greater. Also the extensions and compressions are no longer proportional to the strains. From these causes the position of the neutral axis, and the amount of strain on the different parts of the cross section at the moment of rupture, cannot be determined by theory.

Different theories have been proposed to determine the relative strength of similar beams, while their absolute strength is left to experiment. That of Galileo consists in supposing the beam incompressible, and that it gives way by extension turning round the lower edge, each point of the section giving an equal resistance before rupture. That of Mariotte and Leibnitz supposes the beam in like manner to turn round its lower edge, but considers that the resistance given out by each point of the section is proportional to its distance from that edge.

The theory now generally adopted consists in supposing the extensions and compressions to continue up to the point of rupture proportional to the strains, as is actually the case up to the limit of elasticity, and therefore, that the beam turns round a neutral axis, passing through the center of gravity of the cross section, the force given out by each point being proportional to its distance from the neutral axis. This last theory is found to give the best results in the case of timber and wrought-iron, especially wrought-iron arranged in the forms usual in girders. The second represents nearly the method of failure of stone, and the first that of cast iron.

Though none of these theories give accurate results, they yet give us means of determining, from particular experiments, the strength of any other beam whatever. For example, these theories agree in giving the strength of a rectangular beam to be proportional to the area of cross section multiplied by the depth, and inversely proportional to the length of the beam, since the strain increases directly as the length. This, when expressed mathematically, is

$$W = C \frac{bd^2}{l} \quad (I.)$$

Where w = breaking weight in tons.

b = breadth of beam in inches.

d = depth of beam in inches.

l = length of beam in inches.

C = a constant number for beams of the same material, to be determined by experiment.

This result is borne out by experiment—that is to say, the constant C being determined by experiment on one beam, the strength of any other is found by multiplying its breadth by the square of its depth and by the constant C , and then dividing by its length. In the case of a beam supported at each end and loaded by a weight in the middle, the strength is also given by the formula,

$$W = c \frac{bd^2}{l} \quad (II.);$$

but c , in this case, is 4 times the value of C in the formula for a beam loaded at one end

The truth of this may be seen from the consideration that the beam may be treated as if it were two beams, each fixed at the middle point at one end, and pressed upward by the reaction of the supports at their other ends. This reaction is evidently equal to $\frac{W}{2}$; so that the breaking weight of the whole beam, supported at both ends, resolves itself into that of a beam of length $\frac{l}{2}$, acted on by the weight at one end $\frac{W}{2}$; this by formula (I.) is,

$$\frac{W}{2} = C \frac{bd^2}{\frac{l}{2}}$$

$$\text{or, } W = 4C \frac{bd^2}{l} = c \frac{bd^2}{l};$$

therefore, $c = 4C$ or $C = \frac{1}{4}c$.

Experiments on the transverse strength of beams are generally made by loading in the middle beams supported at both ends. The following table, from experiments by Mr. Barlow, gives the value of c for beams supported at each end and loaded in the middle:

	Tons.
Cast-iron.....	13½
Wrought-iron.....	12
English oak.....	2½
Red pine.....	2½

These numbers when substituted in the formula give the breaking weight, one-third of this will be the safe load in practice. The transverse strength of cast iron is considered so good a test of its value, that in specifications of iron work, it is generally required to be of such a quality that a bar of it, of certain dimensions, will bear a specified weight at the center; for example, "that a bar of it, 42 in. long, 2 in. deep, and 4 in. wide, set on bearings 36 in. apart, shall bear, without breaking, 30 cwt. suspended in the middle." If a beam be loaded uniformly over its length, it will bear twice as much as if the load be condensed at the center. Also if the load be placed some distance from the center, the load it will bear is to the load borne at the center inversely as the rectangle of the segments into which the beam is divided by the point of application of the load are to one another, from which it follows that it will bear less weight at the center than at any other point.

Since the strength of a rectangular beam is proportional to the square of the depth, multiplied by the breadth, it is evident that by increasing the depth and diminishing the breadth we shall, up to a certain limit, increase the strength of a beam without increasing its weight; for example, let A and B be the sections of two beams, of which A is 2 in. broad and 2 deep, and B 4 in. deep and 1 in. broad, they are of the same sectional area—viz., 4 sq. in., but the strength of B is to the strength of A as $4^2 \times 1$ is to $2^2 \times 2$, or as 16 to 8, that is to 1, that is to say, B is twice the strength of A. Hence arises the advantage of the double T forms so generally used in iron girders, the strength of which forms are proportional to the area of the top or bottom plates multiplied by the depth. For a beam of this form loaded at the center, the following formula will give the breaking weight:

$$W = C \frac{ad}{l}$$

Where a = the area of the top or bottom flange in sq. inches.

C = { 4 times the destroying load per sq. in. of the material, under direct ten-

sion or compression in tons.

d = depth of the beam in feet.

l = length between supports in feet.

W = breaking weight at the center in tons.

For cast-iron beams, when the area of the bottom flange is made 6 times that of the top, which has been found by experiment to be the best arrangement, and the strength is measured by the tensional strain, supported by the bottom flange, that is, $6\frac{1}{2}$ tons per sq. inch.

$$C = 6\frac{1}{2} \times 4 = 26 \text{ tons.}$$

For wrought-iron beams,

$$C = 4 \times 20 = 80 \text{ tons for the lower flange,}$$

$$\text{and } C = 4 \times 16 = 64 \text{ tons for the upper flange.}$$

FIG. 1.

Another way of throwing the great body of the material at a distance from the neutral axis is, to make it into the shape of a tube or hollow cylinder. Let B be the section of a hollow cylinder, the thickness of whose walls is represented by the shaded ring; and A be the section of a solid cylinder of the same material. If the area of A is equal to that of the ring in B, the two cylinders will contain the same quantity of matter, but B will be stronger than A, nearly in proportion as cg is longer than dg .

The principle of hollow structure prevails both in nature and art, wherever strength and lightness have to be combined. It is seen in the stems of plants, especially of the grasses; the bones of animals are also hollow, and those of birds, where great lightness is required, are most so. A feather, with its hollow stem, is perhaps the best instance of the union of strength and lightness that could be given. In art, again, we have hollow metal pillars; and sheet-iron for roofing and other purposes is *corrugated*, or bent into ridges and furrows, to give it depth. Each ridge or furrow is, as it were, half a tube, and resists bending with twice or thrice the energy it would if flat.

The most striking application of the principle of hollow structure is seen in tubular bridges. The object being to resist a vertical strain, the form is made rectangular, and the chief mass of the material is thrown into the top and bottom. The tube may, in fact, be considered as an immense beam or girder constructed on the principle of the double T-iron girder, the top and bottom being the two flanges, and the two sides serving to connect them instead of the one rib in the middle. As it is constructed of plate-iron, the top requires more metal than the bottom, in order to resist the compression; but instead of putting the metal into one thick plate, or into several plates, laid the one on the other, it is made to form a set of minor tubes or cells, which give additional stiffness and strength to the whole tube. The floor, in like manner, contains cells. Each of the tubes over the Conway bridge is 24 ft. high, 14 ft. wide (outside), and 420 ft. long, and weighs 1,300 tons; yet these enormous hollow beams sustain not only their own weight, but the heaviest railway-trains without sensible deflection.

FIG. 2.

Fig. 2 represents an ingenious contrivance for strengthening the wooden beams supporting a bridge. An iron rod fixed to the beam AB at the two ends, is kept at a distance by struts c, c' . The beam cannot now be bent downward without stretching the rod; which thus has to bear the tensile strain while the beam itself sustains only the compressive strain.

Another way of removing part of the strain from a girder, is to fix a king-post and two oblique pieces on its upper side. The whole is now one composite girder; and

when any weight bears upon it, the whole of the compressive strain is thrown upon the oblique pieces, and only the tensile strain is left for the beam to sustain.

When a beam AB is fixed at one end, and loaded at the other, the strain is greatest at B, and is less at other points c, c' , in proportion as Ac, Ac' , the levers at which it acts, are less than AB. The beam may therefore be made to taper off toward the end, and we may determine the exact form the beam should have, in order to be equally strong at every point. For supposing the breadth uniform, the strength increases as the squares of the depths $c'd', cd$, while the strain increases as the levers Ac', Ac ; and thus, if $Ac : Ac' :: cd^2 : c'd'^2$, the strengths are equal at those points. This proportion will always hold good, if the curve of the beam is that of a parabola; and, accordingly, this is the shape given to the beams of steam-engines.

In beams supported at both ends, the strain is greatest in the middle; girders are therefore made strongest in the middle, and taper toward the ends.

4. *Shearing Strain.*—This force is called into play when a plate is cut by shears, or when a riveted or bolted joint is torn asunder, in which case the rivets are sheared across. The effect of it is to cause the particles in one plane to slide over those in another; this is resisted by their mutual coherence, and the magnitude of the resistance depends on the number of the particles, that is on the area of cross-section of the body sheared. The following laws are the result of experiment: 1. The ultimate resistance to shearing is proportional to the area of section of the bar sheared. 2. The ultimate resistance of any bar to a shearing strain is nearly the same as the ultimate resistance of the same bar to a direct longitudinal strain.

5. *Torsion.*—If one end of the axle or shaft of a wheel is immovably fixed, and a power acts at the circumference of the wheel (or at the end of a lever or winch), the power may be so increased as to twist the shaft asunder at its weakest point. If a shaft A has twice the diameter of another shaft B, there will be four times as many fibers in the section of fracture of A, to resist the twist, as in that of B. But as the separation takes place by the one end of the fracture turning round upon the axis of the shaft, making the ends of the separating fibers describe circles, those fibers that are furthest from the center will have the greatest power of resistance, and the sum of their moments,

FIG. 3.

or their united effect, will be in proportion to their mean distance from the center. This mean distance in A is twice that in B; therefore, the resistance in A is 2×4 , or 8 times the resistance in B. Generally, the strength of shafts to resist torsion is as the cubes of their diameters. The torsive strengths of shafts 1 in. diameter, and with weights acting at 1 ft. leverage, being found by experiment for different materials; the strength of shafts of other dimensions is found from these "constants" by multiplying by the cube of the diameter, and dividing by the length of the lever. It is evident that the torsive strength of a hollow shaft will be greater than that of a solid one of the same quantity of material, on the same principle that its transverse strength is greater. The rule used by Boulton and Watt for calculating the diameters of their wrought-iron shafts was as follows:

$$\text{Diameter of shaft in inch.} = \sqrt[3]{\frac{120 \times \text{horse-power.}}{\text{Revolu. per minute.}}}$$

This is found to make the shafts rather too light; and the following variation gives safer practical results:

$$\text{Diameter of shaft in inch.} = \sqrt[3]{\frac{240 \times \text{horse-power.}}{\text{Revolu. per minute.}}}$$

STREPSIPTERA (Gr. twisted-wings), an order of insects called RHUPIPTERA (Gr. fan-winged) by Latreille, but first established by Kirby. The first-known species were observed by Rossi, and referred by him to the order *hymenoptera*. The order strepsiptera consists of a small number of species, very singular in structure and habits, apparently forming a connecting link between *coleoptera* and *hymenoptera*. The species are all small, and in their larval state, live parasitically in the bodies of bees and wasps. Their natural history has been the subject of much attention since they were discovered; but much still remains obscure. The species form the two genera, *stygops* and *zenos*.

STRETCHING-COURSE, in masonry or brick-work, is a course in which the stones or bricks are placed with their longest sides along the face of the wall. The stones are called *stretchers*, as those placed at right angles to them with their end exposed are called *headers*.

STRETTO (Ital. bound), in music, a term which signifies that the movement to which it is prefixed is to be performed with rapidity gradually accelerating toward the close.—The term *stretto* is also applied to the recurrence in a fugue of the subject in one part before it has come to a close in another. See **FUGUE**.

STRIFE, the fillets between the flutes of columns, pilasters, &c.

STRICKLAND, AGNES, an English authoress, the daughter of Thomas Strickland, esq., was b. at her father's seat, Reydon hall, near Southwold, in Suffolk, in the year 1806. She was the third daughter of a family of six daughters and two sons, nearly all of whom have contributed something to the literature of our time. Her first compositions were mostly in the poetical vein, and consisted of anonymous contributions to periodicals. About the year 1825, however, she published, in conjunction with her sister Susanna (afterward Mrs. Moodie), a volume of *Patriotic Songs*; which was followed, in 1826, by a little volume bearing her own name exclusively, and entitled *Worcester Field, or the Cavalier; a Poem, in Four Cantos, with Historical Notes*, which was favorably received by some of the reviews. *Worcester Field* was followed by *The Seven Ages of Woman, and other Poems* (Lond. 1827); and this by *Demetrius, a Tale of Greece, in Three Cantos* (Lond. 1833), written in the meter of Byron's *Corsair*. In 1836 she published a little volume entitled *Floral Sketches, Fables, and other Poems*; republished in 1861. With this the list of Miss Agnes Strickland's poetical works ends. Among her prose works are: *The Rival Crusoes*, published without date; *The Pilgrims of Walsingham, or Tales of the Middle Ages, an Historical Romance* (2 vols., 1835); *Tales and Stories from History* (1836); *Alida, the British Captive* (1841); *Historical Tales of Illustrious British Children* (1847; new ed., 1858); *Historic Scenes and Poetic Fancies* (1850); *Old Friends and New Acquaintances* (2 series, 1860–61). All these, however, are but of small import in comparison with her well-known work, *Lives of the Queens of England from the Norman Conquest, with Anecdotes of their Courts*, in 12 vols. (Lond. 1840–48; new ed., 8 vols., 1851–52). In this work, the materials for which she discovered by diligently ransacking among the treasures of the British museum and other great public repositories of historic documents, Miss Strickland was largely assisted by her sister Elizabeth, an assistance which she gratefully acknowledges in her preface. It was dedicated to queen Victoria; and as each volume successively appeared, its picturesque style and anecdotal character made it a general favorite, especially among that class of readers whose object in reading history is rather amusement than philosophical instruction. At the same time it must be owned that in these *Lives* she has added materially to our stock of historical information. Miss Strickland's *Lives of the Queens of England*, concluding with the biography of queen Anne, have been followed by the *Lives of the Queens of Scotland, and English Princesses connected with the Royal Succession of Great Britain*, in 8 vols. (Edin. and Lond. 1850–59); and these by her *Lives of the Bachelor Kings of England* (Lond. 1861), containing the lives of William Rufus, Edward V., and Edward VI. Miss

Strickland published a novel entitled *How will it End?* (1865); *Lives of the Seven Bishops* (1866). In 1871 she received a pension of £100. She died in July, 1874.

STRICKLAND, HUGH EDWIN, 1811-53; b. England; studied with Dr. Arnold at Laleham; graduate of Oxford, 1832; gave his attention to the special study of geology and ornithology. In 1850 he became reader in geology in the university of Oxford, succeeding Dr. Buckland, and retaining the post till his death. He was one of the founders of the geological society, and of the Ray society, which on account of his representations undertook the publication of Agassiz's *Bibliographia Zoologie et Geologie*, 3 vols. of which he edited. He contributed to scientific periodicals, and was associated with sir Roderick Q. Murchison in his *Silurian System*. He was killed by a railway train while making investigations near Claborough tunnel, on the Gainsborough and Retford railway.

STRICTURE is a term employed in surgery to denote an unnatural contraction, either congenital or acquired, of a mucous canal, such as the urethra, œsophagus, or intestine. When, however, the affected part is not mentioned, and a person is stated to suffer from stricture, it is always the urethral canal that is referred to. Contraction of this canal may be either permanent or transitory; the former is due to a thickening of the walls of the urethra, in consequence of organic deposit, and is hence termed organic stricture; while the latter may be due either to local inflammation or congestion, or to abnormal muscular action; the first of these varieties may be termed inflammatory or congestive stricture; and the second, spasmodic stricture. The last-named form seldom exists except as a complication of the other kinds of stricture. There are two principal causes of organic stricture—the first being inflammation of the canal, and the second injury by violence. Inflammation is by far the most common cause, and gonorrhœa is the common agent by which it is excited. Not unfrequently, stimulating injections thrown into the urethra, with the view of checking the gonorrhœal discharge, excite an inflammatory action, which gives rise to stricture. Fortunately, it is only in exceptional cases that a stricture results from inflammation of the urethra, the inflammation, in the great majority of cases, terminating by resolution, and leaving the canal as healthy as before the attack. It is when the complaint assumes a chronic character that it most commonly lays the foundation of stricture. Stricture from the second cause arises from such cases as falling across spars, scaffolding, ladders, etc., or on some sharp object which punctures the perineum, as from earthenware vessels which break under the sitter.

The earlier symptoms of stricture are a slight urethral discharge and pain in the canal, behind the seat of the stricture, at the time of micturition. The stream of urine does not pass in its ordinary form, but is flattened or twisted; and as the disease advances, it becomes smaller, and ultimately the fluid may only be discharged in drops. The straining efforts to discharge urine often induce tenismus (q.v.).

As the case advances, the urine becomes alkaline and ropy, and deposits a precipitate when allowed to stand; and attacks of complete retention (q.v.) occur with increasing frequency. But these symptoms are not in themselves sufficient to establish the presence of stricture. It is necessary to examine the urethral canal with a catheter (q.v.) or bougie (q.v.), to ascertain whether an organic obstruction exists, whether one or more strictures are present (as many as eight have been recorded, although four are rare; and one is the most common number), and their caliber. The treatment of organic stricture is too purely surgical to be discussed in these pages: it is sufficient to state that its object is twofold, viz., first, to restore the natural caliber of the canal, so far as this can be safely effected; and, secondly, to maintain this patency, after it has been established.

Spasmodic stricture may occur from any of the following causes: The presence of organic stricture or of inflammation of the mucous membrane; from an acrid condition of the urine; from the administration of cantharides, turpentine, etc.; and from the voluntary retention of urine for too long a time. The treatment consists in the removal of the causes as far as possible, and the hot bath. The inhalation of chloroform sometimes gives immediate relief; and several cases are recorded in which, when the spasm occurred periodically, it was cured by quinine. Inflammatory or congestive stricture commonly arises when a recent purulent discharge from the urethra has been checked by external cold or wet. The patient complains of heat, fullness, and soreness in the perineum; the passage of the urine is extremely painful, the stream being small, and ceasing before the bladder empties. The treatment is much the same as that for retention of urine (q.v.).

STRIGAU, or STRIEGAU, a t. of Prussia, province of Silesia, and government of Breslau, is situated on Strigau Water, 32 m. w.s.w. of Breslau. It has manufactures of woollens and linens. Pop. '75, 10,614.

STRIGIDÆ, the family of nocturnal birds of prey, or owls (q.v.).

STRIKE, a term borrowed by geologists from the German *streichen*, to extend, and adopted with the technical meaning it has in that language. It is applied to the direction of the outcrop of a stratum—the line which it makes when it appears on the surface of the earth. This line is always at right angles to the dip of the bed. The angle of dip and the direction of strike are determined by a clinometer and compass. A perfectly horizontal stratum can have neither dip nor strike.

STRIKES. Beginning as early as the middle of the 14th c., the opposition of combined labor to the efforts of employers to regulate the price and hours of labor, has been prominent in economic history; though, indeed, the earliest incident recorded in such history, had a peculiar origin, the reverse of what we have just indicated. The terrible plague of 1348 which continued during eight years, destroyed, it is believed, nearly two-thirds of the human race then existing. In London, 50,000 bodies were buried in one grave-yard; in Venice the number of deaths is said to have been 100,000; in Lübeck 90,000; in Spain the disease raged three years, and carried off two-thirds of the people; in the east 20,000,000 perished in one year. One result of this protracted "dance of death" was a scarcity of labor so great that it became a question as to the possibility of providing for the living. Such a condition, not unnaturally, encouraged the craftsmen to increase the price of their services, with the increase of the demand and of the scarcity. In England this assertion of a claim which could not but be obnoxious, was met by parliamentary enactments, "statutes of labor," and other exercise of the power of the governing class. It was the first "strike," and, as ever since, it was met by force. It was an attempt to take unfair advantage of disaster and death. Subsequent strikes for a rise in wages have been occasioned mostly by a preceding act of cutting them down. The introduction of machinery and the factory system into British labor, was the occasion of serious resistance on the part of skilled labor; as was the case also on the continent of Europe and in America. From this time strikes have been common, whenever laborers wished an increase of wages, or a lessening of the hours of labor. The organization of trades-unions made it possible to conduct these movements on a large and powerful scale; and in many instances—particularly in flush times, and when prices were high—they were successful. Not always conducted, however, with a due regard for existing economic conditions, they have frequently proved abortive for their purpose, and powerful only in creating added and permanent distress among the laboring classes. Little record has been kept of the strikes which have occurred in America, but we know that as early as 1830 they occurred in Boston to secure shorter hours of labor; the trades engaged being carpenters and masons. Strikes have occurred since in various manufacturing towns in Massachusetts about every year; sometimes for shorter hours, sometimes for more pay. In some instances these were accompanied by rioting, and sometimes the militia were ordered out to suppress this. In 1834 several hundred laborers employed in building the Providence railroad, struck for higher wages, and became riotous. This was probably the first railroad strike. As a rule, all the early strikes were unsuccessful, though the continual effort after the "ten-hour" rule for daily labor was eventually successful. In Lowell, Lawrence, Fall River, and other cotton-manufacturing towns in Massachusetts, strikes have been frequent; many of them being accompanied by much bitterness and ill-feeling; and all resulting in serious pecuniary loss to all concerned. In all the large cities strikes have formed a prominent feature of the history of labor. Type-setters, stage drivers, railroad-hands, shoe-makers, and nearly all trades and callings have at one time or another in the past half-century experienced these unfortunate aberrations. But the most important event of this nature, was the memorable railroad strike of 1877; when for two weeks, beginning July 14, 100,000 railroad men and 40,000 miners were "on strike" at once; 6,000 m. of railroad, covering several of the trunk lines, were in the hands of an infuriated mob; the state militia and the U. S. army were found necessary to put down the accompanying riotous conduct, murder, and incendiarism; and more than 2,000 freight cars in Pittsburg alone, with their contents, were destroyed, the destruction of railroad property being estimated at \$10,000,00; while in Chicago, Buffalo, Cincinnati, Albany, and other cities, the amount of loss has never been fully estimated. See COMBINATION, *ante*.

STRING-COURSE, a thin projecting course of stone or brickwork in a wall, generally ornamented with a molding, and made to go around windows or other openings in the wall.

STRINGENDO, a term used in music to denote a gradual acceleration in the time.

STRINGHALT is a peculiar catching up of the horse's limbs, usually of one or both hind limbs. It is most noticeable when the animal is first brought out of the stable, when he is excited, or made to turn suddenly round; it is a variety of chorea or St. Vitus's dance. Although a serious eye-sore, it does not interfere with usefulness, and is quite incurable.

STRINGHAM, SILAS HORTON, 1798-1876; b. N. Y.; entered the navy as midshipman, 1809; was in several actions in the *President* and *Spark*, under Decatur and Rodgers; and in 1819-21 as lieutenant in command of the *Cyane* and the *Hornet* conveyed the first settlers to Liberia and captured many slavers. He was promoted to a captaincy in 1841, and participated in the bombardment of Vera Cruz. On the breaking out of the civil war he was made flag-officer of the Atlantic blockading squadron, and the *Minnesota* was his flag-ship. He commanded the naval force which in connection with the land forces of gen. Butler, captured forts Hatteras and Clark. In 1862 he was retired as rear-admiral. In 1871 he became port-admiral of New York, and resided in Brooklyn at the time of his death.

STRÖBILA. See TAPE WORMS.

STROMBIDÆ, a family of gasteropodous mollusks, of the order *pectinibranchiata*, nearly allied to *buccinidæ* (whelks, etc.) and *muricidæ*. The shell has a canal, the external lip of which, as it attains maturity, becomes more or less dilated, and is marked with a sinus, whence the head issues when the animal comes out. The foot is narrow and small, but is employed in active leaping movements, during which the shell oscillates from side to side. The species are numerous, and are mostly inhabitants of tropical seas. Some of them are among the largest of mollusks. *Strombus gigas* is the largest known univalve. It is found in the West Indies, on reefs in shallow water, and is fished both for the table and on account of the shell. Great numbers of the shells are imported into Britain; 300,000 have been brought to Liverpool in a year. They are sometimes called fountain-shell, from their occasional use as a garden ornament. Their chief use, however, is by cameo-makers, by whom they are valued for their solid and delicately tinted substance. A shell sometimes weighs four or five pounds. Pearls of a delicate pink color are sometimes found in this shell. The *strombi* are sometimes called wing-shells, from the dilated margin of the lip.

STROMBOLI, one of the group of the Lipari islands (q. v.), the most north-easterly of the group, is about 12 m. in circumference, circular in shape, and contains 2,000 inhabitants. It is wholly of volcanic formation, and rises to the height of 3,100 ft. above sea-level. On its western side is a volcano of considerable activity. Sulphur and pumice-stone are gathered in large quantities, and among the chief agricultural products are cotton, wine, and excellent fruits.

STROM NISS. See ORKNEY ISLANDS.

STRONG, GEORGE C., 1832-63; b. Vt.; graduated at West Point, 1857, and held the position of 1st capt. of cadets there for 3 years. In 1861 he was attached to the staff of gen. McDowell and acted as his *aide* at the battle of Bull Run. He afterward served with McClellan and Butler, and distinguished himself at Biloxi, Tangipahoa river, and in the assault on fort Wagner, where he was fatally wounded. He rose to the rank of capt. of ordnance and brig. gen. of vols. Gen. Strong was the author of *Cadet Life at West Point*.

STRONG, GEORGE TEMPLETON, 1820-75; b. New York; educated at Columbia college, and called to the bar. He was prominent in his profession, especially in the department of real-property law. He was one of the founders of the Columbia school of mines, a trustee of Columbia college, a vestryman and the controller of Trinity church, New York, and treasurer of the U. S. sanitary commission during the war of the rebellion.

STRONG, JAMES, S.T.D., b. New York, 1822; graduated at Wesleyan university, Middletown, Conn., 1844; settled at Flushing, L. I., and taught Hebrew and Greek to private pupils; received, though a layman, the degree of S.T.D. from Wesleyan university, 1856; professor of biblical literature and acting president of Troy university, 1858-61; professor of exegetical theology in Drew theological seminary, Madison, N. J., 1868; traveled in the east, 1874. In 1853 he became associated with the rev. Dr. John McClintock in the preparation of the *Cyclopædia of Biblical, Theological, and Ecclesiastical Literature*, he having the department of biblical literature. Since the death of Dr. McClintock he has been the chief editor. He has published also *Harmony and Exposition of the Gospels*; *Greek Harmony of the Gospels*; *Manuals of Greek and Hebrew Grammar*; *Outlines of Theology*; *Appeal to Sunday-school Efforts*; also, articles in the *Methodist Quarterly Review* and *Christian Advocate and Journal*. He prepared the translation of the Book of Daniel for Lange's commentary, and is a member of the Anglo-American committee on the revision of the Bible.

STRONG, JAMES H., b. Canandaigua, N. Y., 1814; son of judge Elisha B.; entered the navy as midshipman, 1829; served in the Mexican war; commander, 1861; capt., 1865. He commanded the steamer *Mohawk*, 1861; the *Pttag*, 1862; and the steam sloop *Monongahela*, 1863-65. In 1863 he transported a division of the secret expedition of gen. Banks's army to Brazos, and aided the troops in taking the battery at Arkansas pass. He was in command of the *Monongahela* during her engagement with the ram *Tennessee* in the battle of Mobile bay; commodore, 1871.

STRONG, NATHAN, D.D., 1748-1816; b. Conn.; graduated at Yale college, 1769; tutor there, 1772; ordained pastor of First church (Congregational), Hartford, 1774, where he remained till his death; was a chaplain in the army in the revolutionary war. He published *The Doctrine of Eternal Misery Consistent with the Infinite Benevolence of God*; *Sermons*, 2 vols.; *The Hartford Selection of Hymns*. He originated and edited the *Connecticut Magazine*, and was principal founder of the Connecticut missionary society. He held a high rank for learning and usefulness, and was noted for shrewdness and wit.

STRONG, THEODORE, LL.D., 1790-1869; b. Mass.; graduated at Yale in 1812, taking the mathematical prize; tutor in mathematics at Hamilton college, 1812-16; professor of mathematics at Hamilton, 1816-27. A new geometrical demonstration by him of the values of sines and co-sines of the sum and difference of two arcs, and a solution of a difficult problem in diophantine analysis, were published in the *American Journal of Science* in 1818. Other important papers appeared in subsequent numbers.

After having mastered the *Principia* of Newton and the subjects added by its commentators, he addressed himself to the study of the more modern analysis of La Grange and Laplace. This required a knowledge of the French language which he did not possess, but he soon taught himself sufficient to be able to read mathematical works in French as well as in English or Latin. In 1827, upon a second invitation from Rutgers college, N. J., he became professor of mathematics and natural philosophy in that institution, and removed to New Brunswick, where he remained during the rest of his life, performing the duties of his chair till 1862. Prof. Strong made many important contributions to mathematical science, among which may be mentioned the solution of what is known as the irreducible case of cubic equations of Cardan, a result which had long been sought in vain. He also devised a method for the application of the binomial theorem for the extraction of the roots of whole numbers. His two principal systematic works are: *A Treatise on Elementary and Higher Algebra* (1859); and *A Treatise on the Differential and Integral Calculus* (1869). Both of these treatises contain much original work. In the Algebra, besides what is mentioned above, there is: 1. A direct investigation of the binomial theorem; 2. A simple method of finding integral algebraic roots; 3. A method of solving quadratic equations without completing the square. 4. The doctrine of continued fractions deduced immediately from the form of the quotients and remainders in common division. 5. A new demonstration of the method used for finding the limits of the real roots of equations, including the theorem of Descartes. 6. A new and much more simple method than that of Sturm for finding the first figures of the real roots of an equation. The work on Calculus, written in his 78th year, and without the aid of notes or books, has many original features, and is divested of technicalities and formulas which have become the accretions of time. It contains a solution, by a new and beautiful method, of the problem, "To find the area bounded by the ordinate of a plane curve drawn through the origin of the co-ordinates by any other ordinate and the intercepted parts of the axis and the curve, supposing the ordinates to be constantly positive between the preceding limits." Prof. Strong was a contributor to various mathematical and scientific journals for the greater part of his life. To the *American Journal of Science* he contributed 22 papers between 1818 and 1845. To the *Mathematical Diary*, published at New York and edited at first by Dr. Robert Adrian and afterward by James Ryan, he also contributed. To the *Mathematical Miscellany*, edited by Mr. Charles Gill at Flushing, L. I., he contributed 22 papers; to the *Cambridge Miscellany*, edited by profs. Peirce and Lovering, seven papers; and to the *Mathematical Monthly*, edited by I. D. Runkle, two papers. He also communicated five different papers to the National academy of sciences from 1864 to 1867 inclusive. Among the papers contributed to the *American Journal of Science* are a systematic discussion of the laws regulating the action of a central force, the path of the curve produced thereby, and the mutual action of a system of bodies; a discussion of the parallelogram of forces, their composition and resolution, and the statical equilibrium. In volume xvi. of the journal, on p. 286, there is a deduction of the differential equation which constitutes the fundamental formula for expressing the angular velocity of a planet in terms of its radius vector, and thence, the force being given, the law of the curve of revolution, and of all curves produced by a central force, corresponding to the result given by Laplace in the first part of his second book of the *Mécanique Céleste*, and to that of Newton in the 41st proposition, section viii., of the *Principia*. He was one of the original members of the National academy of science, and was also a member of the Connecticut academy of arts and sciences at New Haven, of the American academy of arts and sciences at Boston, and of the American philosophical society at Philadelphia.

STRONG, WILLIAM, LL.D., b. Conn., 1808; graduated at Yale college, 1828. He studied law, and after his admission to the bar, 1832, began practice in Reading, Penn. In 1849 he was elected to congress and served two terms, after which he re-sumed practice. In 1857 he was elected a judge of the Penn. supreme court, but resigned four years before the full term (15 years) had elapsed. After two years of practice in the higher branches of the profession, he was appointed associate justice of the U. S. supreme court by pres. Grant.

STRONGYLIDE, a family of nematode worms, possessing the following common characters: The body is round, and sometimes very much elongated, and almost thread-like. The mouth is round, oval, or triangular, and situated at the extreme anterior end of the body. The tail of the male is commonly furnished with a bursa, usually emitting two spicules. The whole family is parasitic, and contains a number of genera. Some of the strongylide are parasitic in man, some in mammals, birds, reptiles, etc.

STRONGYLUS (from the similar Greek word signifying *round*) is the term applied to a genus of the family *strongylidæ* (q.v.) of nematode parasitic worms. The only true strongylus infesting man is the *S. bronchidis* of Cobbold, previously known as *filaria hominis bronchialis*, *humanaria compressa*, etc. The male usually measures rather more than half an inch, while the female is upward of an inch in length. For the general and specific characters of this rare entozoon, the reader is referred to Cobbold's *Entozoa*, p. 357. The worm was originally discovered by Treutter in 1790, who found several

individuals in the bronchial glands of an emaciated subject. In 1845 it was again found by Dr. Fortsitz at Klausenberg in Transylvania, in the lungs of a boy six years old. These are the only two cases recorded by Küchenmeister and Cobbold of its occurring in the human subject; but closely-allied species, *S. paradoxus* and *S. micrurus*, are occasionally found, according to Cobbold, in the lungs and air-passages of the pig and the calf respectively, and Küchenmeister states that he has found a species in the lungs of the sheep.

Closely allied to strongylus is the genus *eustrongylus* of Diesing and Cobbold, which contains the species *E. gigas*, more commonly known as the *strongylus gigas* of Rudolphe, Cuvier, and others. This is the largest nematode worm at present known to infest man or any other animal; "the male measuring from ten inches to a foot in length, and $\frac{1}{2}$ of an inch in breadth; while the female is said to attain a length of over 3 feet, its transverse diameter being fully half an inch; body cylindrical, and more or less tinged with redness; head obtuse, and furnished with a simple oval aperture surrounded by six chitinous nodules: mode of reproduction, probably viviparous; eggs broadly oval, measuring about $\frac{1}{300}$ " from pole to pole."—*Op. cit.*, p. 358. This worm occurs, according to Bremser, in the kidneys and bladder, sometimes in the abdominal cavity and the omentum, more rarely in the lungs and liver of "martens, dogs, wolves, seals, otters, oxen, and horses." Fortunately it is very rare in man, and, according to Cobbold, weasels are the animals in which it is most commonly found. The symptoms to which it must give rise must be much the same as those arising from abscess and degeneration of one of the kidneys, or from renal calculi. The diagnosis in a suspected case could only be established by the detection of the eggs or embryos in the urine.

STRONSAY, one of the Orkney islands, lies 15 m. n.e. from the town of Kirkwall. It is $7\frac{1}{2}$ m. long, and 6 m. in extreme breadth. Pop. '71, 1267.

STRONTIA. See STRONTIUM.

STRONTIUM (symb. Sr, equiv. 43.8—new system, 87.6—sp. gr. 2.54) is a ductile and malleable metal, somewhat harder than lead, and of a pale yellow color. When heated in the air, it burns with a crimson flame, and becomes converted into its oxide, strontia. It is unaffected by the action of dry air, but it decomposes water at an ordinary temperature, hydrogen being explosively developed; and it burns in chlorine gas, and in the vapor of iodine, bromine, and sulphur. It dissolves in dilute nitric acid, but the strong acid has scarcely any effect on it. This metal does not occur in the native state, but exists as a carbonate in the mineral *strontianite* (so called from its being first found near Strontian, in Argyleshire), and as a sulphate in the mineral known as *celestine* (so called from its delicate blue tint). It is obtained by the voltaic decomposition of the chloride of strontium. This metal bears to barium the same close relation that sodium bears to potassium; and the compounds of strontium resemble those of barium not only in their composition but in their properties.

The oxide of strontium, commonly known as **STRONTIA**, is obtained in the same way, and resembles in almost all respects the corresponding oxide of barium, except that it is inert when taken into the system, while baryta is poisonous. When a small quantity of water is poured upon it, it slakes, giving out heat.

The salts of strontia resemble those of baryta in their general characters, and in their being precipitated from their solutions by sulphuric acid and the soluble sulphates; but they differ from them in not being thrown down by silico-fluoric acid or hyposulphite of soda, and in their communicating to the flame of the spirit-lamp and to burning substances generally, a brilliant purple-red color. The salts of strontia occur only in the mineral kingdom, and are never found as normal ingredients of organic bodies. *Carbonate of strontia* ($\text{SrO} \cdot \text{CO}_2$) occurs native both in a massive and crystalline form, and may be obtained artificially as a white powder by precipitating a soluble salt of strontium with carbonate of soda. *Sulphate of strontia* occurs native in *celestine*, a mineral which is found in beautiful rhombic prisms in Sicily. *Nitrate of strontia* ($\text{SrO} \cdot \text{NO}_3$) separates from a hot concentrated solution in large colorless transparent anhydrous octahedral crystals, which dissolve freely in water. By the addition of nitric acid, it is precipitated from its aqueous solution. This salt is insoluble in alcohol; but when finely powdered, and mixed with it, it communicates to the alcoholic flame a beautiful red or crimson color. In consequence of this property, it is employed by the makers of fireworks. A mixture of 40 parts of nitrate of strontia with 10 of chlorate of potash, 13 of sulphur, and 4 of sulphide of antimony, deflagrates with a magnificent red color, and constitutes what is popularly known as *red Bengal fire*; but the mixture is dangerous both to prepare and to preserve, having more than once been the occasion of frightful accidents to the manufacturers from its becoming ignited spontaneously.

The most important of the haloid salts of strontium is the *chloride* (SrCl), which may be obtained in crystals containing six equivalents of water. The water is expelled at a moderate heat, leaving the chloride anhydrous. The chloride is the only salt from which the metal has hitherto been obtained.

Regarding the history of this metal, it may be observed that strontia was discovered as an independent substance almost simultaneously by Hope and Klaproth in 1793. In 1807 Davy obtained barium and strontium from their oxides, but not in a pure state;

and it was not till 1855 that Bunsen and Matthiessen succeeded in procuring perfectly pure specimens of the metal.

STROPHULUS. See RED GUM.

STROSSMAYER, JOSEPH GEORGE, b. Eszek, 1815. After being educated at Pesth, Vienna, and Padua, he became Roman Catholic bishop of the united sees of Bosnia and Sirmia in 1850. He attended the Vatican council of 1869, and the text of a violent speech, opposed to the introduction of the question of papal infallibility, was published in several journals as having been made by bishop Strossmayer. In 1872, however, he wrote a letter to the *Frangais*, in which he denied having made such a speech. He has been for 30 years a zealous promoter of Slavic interests.

STROTHER, DAVID HUNTER, b. Va., 1816; came to New York in 1845 and studied art for several years. In 1853 he first became known to the public as "Porte Crayon," the author of a series of very amusing papers illustrative of travel, scenery, and manners in the south and elsewhere, some of which were afterward collected in *Virginia Illustrated* (1857). He entered the union army as capt., in 1864, resigned, and in 1867 was brevetted brig. gen. After the war he published in *Harper's Monthly* (where all his writings had appeared) a series of *Personal Reminiscences of the War*. In 1879 he was appointed consul-general to Mexico.

STROUD, a parliamentary borough and market t. of Gloucestershire, 9 m. s.e. of the city of Gloucester, stands in a beautiful and extensive valley, at the confluence of the Frome and Slade, which unite to form the Stroudwater or Frome. It is the center of the woolen manufactures of Gloucestershire, and contains a number of woolen and silk-mills. The water of the Frome is peculiarly adapted for use in dyeing scarlet and other grain colors; and on this account cloth-factories and dyeworks have been built along its banks for the distance of 20 miles. The borough of Stroud forms part of the great west of England cloth districts. Pop. of parliamentary borough, which sends two members to the house of commons, '71, 38,610.

STROUSBERG, BETHEL HENRY (DR.), b. Prussia, 1823; of Jewish parentage; original name Baruch Hirsch Strausberg; in early life converted to Christianity; entered the office of his uncles, commission merchants, in London, 1835; married an English woman; failed in the insurance business in 1847; became a teacher of languages in New Orleans, 1848; speculated in damaged goods to such advantage that he was able to return to London in 1849, and assist in publishing *The Chess Player* and other magazines. In 1855 he went to Berlin on insurance business, and negotiated for the East Prussian railway. He became a railroad magnate, building railroads in Germany, Hungary, and Rumania, and owning immense factories for manufacturing railroad materials. He established beet-sugar and porcelain factories, and was the proprietor of the Berlin cattle yard, the citadel grounds at Antwerp, and an immense estate in Bohemia. He engaged in vast speculations, employed 100,000 persons at one time, and has been known in Berlin as *Der Wunderdoctor*. In the war of 1870-71 he met with enormous losses; failed in 1875 in consequence of some transactions with the Rumanian government, and was imprisoned at Moscow in the same year for certain irregularities connected with a bank.

STRUENSEE, JOHANN FRIEDRICH, Count of, a man who, in last century, attracted the attention and excited the sympathy of the whole of Europe, by his elevation and downfall at the Danish court. Struensee was born Aug. 5, 1737, at Halle on the Salle, where his father, Adam Struensee, the author of the old Halle Hymn-book, was pastor of the Ulrichskirche. Young Struensee studied medicine, and when scarcely 19 years old passed as doctor. Early alienated from positive Christianity, he zealously embraced the philosophy which had then arisen in France, and became a disciple of Helvetius and Voltaire. When his father removed to Altona he accompanied him, and was soon afterward appointed traveling physician to the young king, Charles VII. of Denmark; and on their return from a tour, physician in ordinary. At first the young queen, Caroline Matilda, sister of George III. of England, looked upon him with mistrust; and it was not till 1770, when Struensee successfully managed the inoculation of the two-year old crown-prince, afterward king Frederick VI., that she came round to him, intrusted him with the education of the prince, and by degrees made him the confidant of her unhappy position. Struensee removed the estrangement between the royal pair, which was the work of the favorite Holck, and, in consequence, rose still higher in favor with both. He was appointed reader to the king, and private secretary to the queen. Since the revolution of 1660, Denmark had been under the domination of the nobility, who, as a council of state, governed the country. Struensee saw the disadvantages of this government of the nobles, and formed the ambitious resolve to come forward in this land of his adoption as an enlightened reformer after the model of Frederick II. To begin with, he effected the downfall of the favorite Holck, in whose stead his friend Brandt was appointed royal companion and director of the court amusements. In order to gain the love of the people, Struensee proclaimed the freedom of the press. The council was dissolved, and a proclamation issued to the effect that the royal power in all its purity, as it had been handed down from olden times, was to be re-established. These measures amounted in reality to a revolution, and to a declaration of war against the aristocracy. The queen and Struensee, in whose hands the whole power now was, chose new ministers, and excluded

the feeble Christian entirely from the management of affairs. In July, 1771, Struensee received the title of cabinet minister, along with unlimited power. He brought several men from Germany, whom he appointed to different offices. This introduction of strangers caused great dissatisfaction among the people. In opposition to the politics of his predecessors, Struensee endeavored to free Denmark from Russian influence, and to find a natural ally in Sweden. The changes which he undertook in the internal affairs were directed to the advancement of the prosperity of the country, of civil liberty, and enlightenment. He put the finances in order, reduced the expenditure, loosened the fetters in which industry and trade had been bound, encouraged education, mitigated the penal laws, and brought order into the administration. An act passed in 1771 to a certain extent abolished serfage. All these reforms, which are in operation in the Danish dominions at the present day, were excellent; but the haste and want of statesmanlike skill with which they were carried out made them appear as the acts of the most vexatious tyranny. Struensee committed a great mistake, too, in recklessly obtruding his philosophy of enlightenment in the face of the strict orthodox clergy and the pious prejudices of the people.

Struensee had scarcely been in power a year when the symptoms of reaction appeared in all quarters. The queen gave birth to a daughter in 1771, which, in the condition of the king, gave rise to most scandalous reports. The British ambassador, lord Keith, who saw the catastrophe approaching, proposed to Struensee, by the advice of George III., to take refuge in England; but Struensee declined doing so. At the head of the hostile party was Christian VII.'s step-mother, Juliana Maria, princess of Braunschweig-Wolfenbüttel, who was impatient of the domination of the queen and Struensee. A bold stroke was to precipitate Struensee and ruin the queen, and the night when a court ball was to take place was fixed upon for carrying out the plot. The conspirators assembled at the king's stepmother's, and by a secret door entered the bedroom of the king, and obliged him to make out 15 warrants of arrest, among others for Struensee. Christian was prevailed upon, but with much difficulty, to write out orders to arrest and convey his consort the queen to Kronenburg. Struensee and the queen were then taken prisoners, and the former was treated with extreme harshness, put in chains, and brought to the citadel. He was accused of an assault on the person of the king; of the intention to compel Christian to abdicate the throne; of criminal intercourse with the queen; of using a fatal system in the education of the crown-prince; and of the usurpation and abuse of supreme power. Not one of these points could be legally proved. In a second examination, however, Struensee, with tears, confessed to having had improper intercourse with the queen; but some of his contemporaries affirm that he made the confession under threat of torture. On this important confession, a second commission was sent to the queen at Kronenburg, from whom, however, not the slightest confession of guilt could be extorted. When one of the commissioners at last remarked that if she made Struensee guilty of falsehood he would be put to a disgraceful death for slandering majesty, the queen seized a pen, and began to sign a paper which contained the confession of her guilt. She had not finished when she sunk in a swoon in her chair; and it is said that some one put the pen in her hand, and guiding it, finished the name, "Caroline Matilda." Struensee was found guilty of a great and capital crime, and was sentenced to a cruel death. It was wished by some to proceed further against the queen; but the commissioners were satisfied with the simple separation of the royal pair, especially as the British ambassador threatened the appearance of a British fleet. After the king had confirmed the sentence, not without being urged by the Russian ambassador, it was carried into execution, April 28, 1772, amid the rejoicings of the multitude. In the prospect of death, Struensee is said to have returned to the Christian faith. There is no doubt that he did not deserve his fate, but that he fell a sacrifice to the party of the nobles. The execution of his friend Brandt, which took place at the same time, was a still clearer case of legal murder, as he never took any part in the affairs of government. Struensee's brother would have shared the same fate had not Frederick II. claimed him in a menacing manner as a Prussian subject. Queen Caroline Matilda left Denmark in May, 1772, and died of grief in 1775, in the castle of Celle in Hanover.

In recent times Struensee's history has been recalled to memory in a tragedy by Mich. Beer and Heinr. Laube. See HÖST, *Count Struensee and his Ministry* (1824; Germ. Copenh. 1826); Falkenköld, *Mémoires* (Paris, 1826).

STRUTHIONIDÆ. See OSTRICH, *ante*.

STRUTS, straining pieces of timber in a roof, used to strengthen the principal trusses (q.v.).

STRUTT, JOSEPH, 1742-1802; b. England; studied painting, but afterward devoted himself to antiquarian researches. Among his works are *The Royal and Ecclesiastical Antiquities of England* (1773); *The Chronicle of England* (1777-78); *Complete View of the Dress and Habits of the People of England from the Establishment of the Saxons in Britain to the Present Time* (1796-99); and *The Sports and Pastimes of the People of England* (1830).

STRUVE, FRIEDRICH-GEORG-WILHELM, a celebrated astronomer, was b. at Altona, April 15, 1793, educated at the university of Dorpat (Russia), and appointed to a post in the observatory of that place in 1813. He became director of the Dorpat

observatory in 1817, and continued with the utmost assiduity his observations and researches respecting double and multiple stars, adding immensely to our knowledge of these systems; and earning for himself the reputation of being one of the most skillful of practical astronomers. The instrument with which he observed was a Fraunhofer's (q.v.) refractor, of 10 in. aperture, and $13\frac{1}{2}$ ft. focal length; and with this telescope, in gleaning from the depths of space the materials for his three important works on double stars (1822 and 1828, 1837 and 1840, 1852), he examined no fewer than 120,000 of these twinkling luminaries. His investigations have led him to the conclusion, that the number of true double stars is much larger than was previously supposed (see STARS). Struve also executed a number of important geodetic operations, such as the triangulation of Livonia, in 1816-19, and the measurement of an arc of the meridian in the Baltic Provinces, in 1822-27; which was subsequently (1828-56) extended by him in conjunction with Hansteen (q.v.) and Selander, to the North Cape; and by gen. Tenner southward to Ismail in Turkey. This latter undertaking, the most extensive trigonometrical operation ever performed, when completed, gave the length of a meridian arc of 20° , and enabled geometers to determine with increased accuracy the exact form of the earth. Meanwhile, Struve had been appointed, in 1839, director of the best organized observatory in the world, that of Pulkova (q.v.), and also chosen *correspondant* in the astronomical section of the academy of sciences of Paris. He died at St. Petersburg Nov. 23, 1864.—His son, OTTO-WILHELM STRUVE, also an eminent astronomer, was born at Dorpat, May 7, 1819, was educated under his father's direction, became his chief assistant at Pulkova, and the director of the observatory after his death. He has made numerous astronomical discoveries, among which are more than 500 new double stars, and (1847) a satellite of Uranus, and has written numerous important papers, the most noticeable of which set forth his researches on the inner or dusky ring, and on the variation in breadth of the bright rings of Saturn, and on the periodic motions of double stars.

STRYCHNIA, or STRYCHNINE. See NUX VOMICA.

STRYCHNOS, a genus of trees of the natural order *loganiaceæ*, having a five-lobed calyx, a tubular funnel-shaped or salver-shaped corolla, with a five-partite limb, five stamens, a filiform style, numerous ovules, and a one-celled berry, with a leathery rind, many-seeded, or, by abortion, one-seeded, the seeds discoidal and compressed. To this genus belongs the *S. nux vomica*, a tree of middling size, with ovate-stalked leaves, a native of India, the fruit of which is produced in great abundance, and is about the size of a small orange; the seeds are the *nux vomica* of commerce, and yield *strychnine*. The bark partakes of the poisonous quality of the seeds. The wood of the tree is very hard and durable. The clearing-nut (q.v.), and St. Ignatius' (q.v.) bean are produced by species of this genus, to which also belongs the tree (*S. torjera*) which produces the woorai or curare (q.v.) poison of South America. Another species is the *UPAS TIETÉ* (*S. Tieté*) of Java, a large climbing shrub, the bark of which is extremely poisonous, containing a very large quantity of strychnine. The wood of a species found in the north of India (*S. colubrina*), which is also a climber, is an imaginary cure for snake-bites. The bark of *S. pseudo-quina*, a Brazilian species, is used as a substitute for cinchona.

STRYPE, Rev. JOHN, a voluminous ecclesiastical historian, was b. in London in 1643. He studied at Cambridge, entered the church, and held for many years, with other smaller livings, the rectory of Low Leyton, in Essex. He died at Hackney in 1737, having reached the great age of 94. His works fill thirteen large folio volumes. The most important are—*Memorials of Archbishop Crammer* (1694); *Life of Sir Thomas Smith, secretary of state to Edward VI. and Elizabeth* (1698); *Lives of Bishop Aymer* (1701), *Sir John Cheke* (1705), *Archbishop Grindal* (1710), *Archbishop Parker* (1711), and *Archbishop Whitgift* (1718); *Annals of the Reformation* (vol. i. 1709, vol. ii. 1723, vol. iii. 1728, and vol. iv. 1731); *Ecclesiastical Memorials*, relating to religion and the church of England under Henry VIII., Edward VI., and queen Mary, in 3 vols. folio, published in 1721. This is his best work, forming, with Burnet's more readable *History of the Reformation*, a consecutive and full account of the reformed Anglican church. Strype also published an enlarged edition of Stow's *Survey of London*, with several sermons and pamphlets. As a writer, he is heavy, but honest and plodding, and he was a faithful transcriber of the ancient papers he published, which, he says, were all copied with his own hand.

STUART, Lady ARABELLA, or ARBELLA, 1575-1615, b. England, daughter of Charles Stuart, earl of Lennox, and cousin of James I. Her relationship to Elizabeth gave rise to a number of plots to put her on the throne. Several schemes to marry her were defeated by Elizabeth. In 1603 sir Walter Raleigh was charged with a plot to place her on the throne. In 1610 it was discovered that she had made a secret marriage with William Seymour, grandson of the earl of Hertford. Seymour was imprisoned in the Tower, and she was put in the custody of the bishop of Durham, but escaped to a French vessel, in which her husband, who had escaped from the Tower, was also to sail. He did not reach it, and it sailed and was captured. He escaped, however, in another vessel. Arabella spent the rest of her life in the Tower, and finally became insane.

STUART, CHARLES EDWARD LEWIS CASIMIR, often called the younger pretender, the eldest son of James Francis Edward, prince of Wales, known as the elder pretender, or chevalier St. George (see **SREWART, FAMILY OF**), and his wife Clementina Sobieski, granddaughter of the celebrated Polish monarch, John Sobieski. He was born at Rome, on Dec. 31, 1720, and bore among the Jacobites the title of prince of Wales. He served under don Carlos in Spain, and in his youth is described as having been handsome, affable, and engaging in manners. In 1743 28 years after his father's unsuccessful attempt to regain the crown, a scheme was contrived in France, with the support of the Jacobites in England, by which Charles Edward was to recover the throne of Great Britain for his family. The first contrived project was to land an army in Kent, where were many adherents of the exiled house; and troops to the number of 15,000 were assembled, and transports provided at Boulogne, Dunkirk, and Calais to carry them to England. But the squadron which was to have convoyed the transports fled before the British fleet under sir John Norris; a storm destroyed the transports, and most of the troops were drowned. Charles, however, only awaited a favorable opportunity to make a fresh attempt. In July, 1745, when George II. was in Hanover, and Scotland almost without military, he sailed from Nantes, in company with the marquis of Tuillibardine, and a few other devoted followers, and landed in the bay of Lochnanuagh, whence he proceeded to Kinlochmoidart, where the Highland clans attached to his cause were summoned to rise. Ten days later, Charles's standard was set up at Glenfinnan; and he marched southward at the head of a large body of hardy mountaineers. Government offered a reward of £30,000 for the apprehension of the pretender's son, who retaliated by offering a like reward for the apprehension of the elector of Hanover. At Perth, the insurgents were joined by the duke of Perth and lord Strathallan, with a numerous retinue of followers; and on their approach, Edinburgh surrendered without resistance, the castle, which was in possession of the king's troops, still holding out. Charles took up his residence at Holyrood palace, where he proclaimed his father king of Great Britain, and him-self regent.

Meanwhile, sir John Cope, the commander-in-chief of the king's troops in Scotland, having collected some re-enforcements in the n., came from Aberdeen to Dunbar by sea, and encamped at Prestonpans. He was there unexpectedly attacked by the Highlanders, and ignominiously routed, leaving baggage, cannon, and camp equipage on the field. Contrary to the advice of his council, Charles, who could not bear opposition, resolved to advance into England, though his force hardly exceeded 6,500 men. Carlisle surrendered at his approach, and he proceeded unmolested as far as Derby. In the mean time, three English armies, each larger than his own, were preparing to meet him. Being unable to raise any recruits in England, he found it necessary to retreat into Scotland, where he hoped to meet a re-enforcement under lord John Drummond. On their way n., the Highlanders were pursued by the duke of Cumberland, whom they defeated near Penrith. Finding that Edinburgh was now in possession of the king's troops, Charles, joined by lord John Drummond and lord Strathallan, made his way to Stirling. That town surrendered to him, and he laid siege to the castle. Gen. Hawley, in endeavoring to raise the siege, was utterly routed by lord George Murray, at the head of the Macdonalds of Keppoch. But the advance of the duke of Cumberland obliged the rebels to retreat further n., and for a time they carried on a desultory war with the king's troops in the neighborhood of Inverness. On April 16, 1746, the duke of Cumberland encountered Charles's army on Culloden moor, and opened a heavy cannonade on them. The Highlanders at first rushed boldly forward; but on the advance of the royal infantry, they gave way; the battle soon became a rout, and the fugitives were pursued and slaughtered by the dragoons, who gave no quarter, and spread carnage and desolation over the country. The rebels lost that day at least 1000 men of the bravest and most devoted to the cause. Charles escaped to the Hebrides, hunted by the king's troops; disguised in female attire, he was conveyed to Skye in an open boat by Flora Macdonald, daughter of Macdonald of Milton. For months he wandered in concealment among the mountains of Skye and the mainland, where he had many hairbreadth escapes; and though his secret was known to hundreds of the poorest of the people, no one was tempted by the £30,000 reward to betray him. He eventually escaped to France, and no further attempts were made to reinstate the exiled family.

Charles Edward remained in France till the peace of Aix-la-Chapelle (1748). It was made a condition of that treaty that France should abandon the cause of the Stuarts; and Charles, refusing to quit France voluntarily, was conducted with a guard out of the kingdom, and retired to Rome.

He married on April 17, 1773, Louisa Maximiliana de Stolberg-Guedern, daughter of Gustavus Adolphus, prince of Stolberg Guedern. The union did not prove a happy one, and the princess withdrew herself from him. See **ALBANY, COUNTESS OF**. In the latter years of his life, the prince was addicted to intoxication. When his claims ceased to be supported by any foreign power, he dropped the title of prince of Wales, and assumed that of count of Albany. He died at Rome, Jan. 31, 1788, and was buried at Frascati. There was no issue of his marriage, but he left a natural daughter, on whom he bestowed the title of duchess of Albany, and to whom he bequeathed considerable property.

Two brothers, generally known as John Sobieski Stuart and Charles Edward Stuart,

endeavored, some years ago, to persuade the world that they were legitimate grandsons of Charles Edward. In point of fact, they were sons of captain Thomas Allen, R.N., and grandsons of admiral John Carter Allen, who died in 1890. Their story, as set forth, with some slight mystifications, in a work called *Tales of the Century, or Sketches of the Romance of History between the Years 1746 and 1846*, was to the effect that their father, in place of being admiral Allen's son, was a son of prince Charles and the princess Louisa, whose birth was kept secret, from fear of the Hanoverian family, and who was intrusted to admiral Allen, and passed off by him for his own son. The life of Charles Stuart is detailed in *History of the Rebellion, 1745-46*, by R. Chambers.

STUART, GEORGE HAY, b. Ireland, 1816; educated at Bainbridge, emigrated to the United States, and engaged in business at Philadelphia; is distinguished as an active Christian philanthropist; during the rebellion was president of the U. S. Christian commission, and afterward of the Indian commission; is president of the Philadelphia branch of the evangelical alliance; a vice-president of the American Sunday-school union, Bible and tract societies. For many years he was very prosperous in business, and is now president of a national bank in Philadelphia.

STUART, GILBERT CHARLES, American painter, was b. at Narragansett, Rhode Island, in 1756. In his boyhood, he went to Edinburgh with a Scotch painter named Alexander, with whom he studied his art; but his master dying, he worked his passage home, and began to paint portraits at Newport. In 1778 he made his way to London, where he led for two years a wild Bohemian life; but his talent was recognized by his countryman, Benjamin West, president of the royal academy, who took him into his family, and whose full-length portrait he painted for the national gallery. In 1781 he opened his studio in London, and painted the portraits of his majesty George III., R.R.H. the prince of Wales, the duke of Northumberland, sir Joshua Reynolds, John Kemble, col. Barré, and many other celebrated characters. He also made a professional visit to Dublin, and in Paris painted a portrait of Louis XVI. In 1793 in the fullness of his powers and fame, he returned to America, and painted portraits of Washington, Jefferson, and many of the distinguished men of the period, and commenced a portrait of John Quincy Adams, which at his death was finished by Sully. He died at Boston, July, 1828.

STUART, JAMES E. B., 1832-64; b. Va.; graduated at the U. S. military academy, West Point, 1854. He was engaged on the frontier fighting Indians, under Sumner and Joseph E. Johnston, and became noted for his daring. In 1857 he was severely wounded while fighting a party of Cheyennes. In May, 1861, president Lincoln appointed him a capt. in the U. S. cavalry, but he declined the appointment to accept from the confederates that of col. of a Virginia cavalry regiment. He commanded the confederate cavalry at the battle of first Bull Run; and in September was appointed brig. gen., and given command of all the Virginia cavalry. He made several successful raids on the union positions, and was appointed maj. gen. in the confederate army, and placed in command of a division of cavalry. On Aug. 22, 1862, he made his famous dash at the right flank of gen. Pope's army, at Catlett's station. During a heavy storm he penetrated to Pope's headquarters, where he succeeded in capturing important papers, besides obtaining the private effects and dress uniform of gen. Pope, and of several of his officers. He made important raids after Antietam; in the Chancellorsville campaign; and during Lee's invasion of Pennsylvania; and covered the confederate retreat after the battle of Gettysburg. He was defeated by Sheridan's cavalry in the Wilderness; and on May 12, 1864, was mortally wounded in an engagement with them near Richmond; to which city he was taken, and where he died on the evening of the same day.

STUART, MOSES, American divine and author, was born at Wilton, Conn., Mar. 26, 1780, and educated at Yale, where he remained for some time as a tutor. He began the study of law, but abandoned it for theology; was ordained as pastor of a Congregational church at New Haven in 1806; and in 1809 was appointed professor of sacred literature at the theological school at Andover, a position he filled till 1848. During this period, in addition to his professorial duties, he wrote a *Grammar of the Hebrew Language*, without points; *Letters to the Rev. W. E. Channing; Hebrew Grammar*, with points (based on Gesenius); *Commentaries on the Epistle to the Hebrews*, and the *Epistle to the Romans*; on the books of *Ecclesiastes*, *Proverbs*, *Daniel*, and the *Apocalypse*; *Hebrew Chrestomathy*; *Essay on the Liquor Traffic*; *Essay on Christian Baptism*; *Hints on the Prophecies*; *Conscience and the Constitution*—manifesting in all acuteness, vigor, and versatility. He died at Andover, Mass., Jan. 4, 1852.

STUART, MOSES (ante), has been called the father of biblical science in this country. While his own contributions to it are of great value, he accomplished still more by the impulse which he gave to others. Studying the Hebrew language with enthusiasm, he infused the same spirit into his classes. He quieted apprehensions concerning the "various critical readings" by announcing that almost all related to unimportant matters, and that the rest, while they change the sense of some particular passages and omit phrases and words, disprove no doctrine, take away no precept, and alter no important fact. To him belongs the honor of opening the treasures of German literature to American minds. His great work was to redeem theology from iron handed metaphysics and call it back to the Scriptures.

STUCCO, a composition used for the finer parts of plaster-work, such as cornices, enrichments, etc. Gypsum (q.v.), or plaster of Paris, is used for this purpose. A coarser kind of stucco is also used for making floors, and for plastering the exterior of buildings.

STUFFING, in cookery, means force-meat used for filling the bodies of small animals, such as poultry, or for stuffing openings made for the purpose in large joints. It usually consists of bread-crumbs, savory herbs, and other seasonings, minced very fine, and made into a paste.

STUHLWEISSENBERG (Hung, *Székes Fejérvár*, Slav. *Bielhrad* or *Bialigrad*, Lat. *Alba Regalis* or *Alba Regia*), a royal free town of Hungary, and seat of a bishop, lies in a swampy plain in the neighborhood of the marshes of Sár-Rét, 16 m. n.e. of lake Balaton. The principal buildings are the splendid cathedral of the Virgin Mary, the church of St. John, and the bishop's palace. It has several Catholic schools, a military academy, and a theater. The inhabitants manufacture cotton cloths, flannels, leather, silk, and knives ("Stuhlweissenburg clasp-knives"), and extract soda from the swamps, which are, moreover, rich in fish, crabs, tortoises, and water-fowl. Pop. '70, 22,683. Stuhlweissenburg is built on the site of the Roman *Floriana*, and from 1027 to 1527 was the place where the kings of Hungary were crowned and buried, 14 of whom repose here. In later times it suffered much from the ravages of war, and was for some years in the hands of the Turks.

STÜPA. See TOPE.

STURDY, or the *Gr.*, affects sheep, and occasionally cattle, and is caused by the presence within the brain of a hydatid, reaching sometimes the size of a hazel-nut, and floating in a watery fluid inclosed in a membranous sac. This hydatid, when given to dogs, is known to produce tape-worms, and conversely itself originates from the ova of the tape-worm ejected on the pastures by dogs, rabbits, or even by sheep themselves. In the state of ova, or in some of its earlier minuter transitional forms, the hydatid embryo is picked up along with the grass, passes into the blood, and is thence laid down in the soft loose textures of the brain. It is most common in low damp pastures, and amongst sheep from six to twenty months old. The animal cannot properly seek its food, loses condition, staggers when moved, turns stupidly round almost in one spot, and usually toward the side on which the hydatid lies. The parasite and its sac may generally be safely removed by placing the sheep, with its feet tied, on a table or bench, searching for the softened portion of the skull, which generally overlies the hydatid, laying back a flap of skin, and introducing the trochar and canula, and when the sac is deep-seated, cautiously withdrawing it with the help of a small syringe. Protected by a leather cap and simple water-dressings, the wound speedily heals.

STURGE, JOSEPH, 1793-1859; b. England; began business in 1820 as a corn-factor in Birmingham, where he amassed a large fortune. He belonged to the society of Friends, and was deeply interested in securing the abolition of slavery. He visited the West Indies and the United States for the purpose of studying the slavery question. He wrote *The West Indies* in 1837, and *Visit to the United States* in 1841.

STURGEON, *Acipenser*, a Linnean genus of cartilaginous fishes, now forming the family *sturioidæ*, and placed by Müller in the order of *ganoids*, distinguished by the ganoid (q.v.) scales or bony shields which form the external covering. The gills are free, as in the osseous fishes. The vertebral column is soft; and there are no evident sutures in the skull. Reproduction is by roe, as in osseous fishes. The form of sturgeons is elongated and angular; the plates are arranged in regular rows; the head is cuirassed; the snout long and conical; the mouth is on the under surface of the head, tubular, protractile, and without teeth. The upper lobe of the tail is much larger than the under. The dorsal and anal fins are opposite to one another, behind the ventrals. The air-bladder is very large, and communicates with the gullet by a large hole. The species of sturgeon are numerous, and inhabit both the sea and fresh water, ascending deep muddy rivers at certain seasons, and temporarily inhabiting lakes. Numerous species are found in the northern parts of the world, although there are none in the Arctic ocean, or the rivers which flow into it, but the s. of Siberia and North America particularly abound in them. They are plentiful in the Caspian and Black seas, and in the rivers connected with them, where the sturgeon fishery is of great importance, supplying the inhabitants of large districts with their chief article of subsistence, and producing great quantities of caviare (q.v.), or preserved sturgeon roe, and of isinglass (see GELATINE), for sale. The COMMON STURGEON (*A. sturio*) is sometimes caught in the mouths of British rivers, most frequently in salmon-nets; and is a large fish, 6 or 8 ft. in length, with five rows of flattened plates; the muzzle long and pointed. Another species (*A. latirostris*), with broader muzzle, also visits the British coasts, but they are not popularly distinguished. The sturgeon is more abundant on the northern coast of Europe. It is also found in the more southern parts, and was in very high repute for the table among the Greeks and Romans. At their banquets it was introduced with particular ceremonies. In England, when caught in the Thames, within the jurisdiction of the lord mayor of London, it is a *royal* fish, reserved for the sovereign. Its flesh is white, delicate, and firm. It is used both fresh, generally stewed, and pickled or salted.—The

largest species of sturgeon is the BIELAGA, or HUSO (*A. huso*) of the Black and Caspian seas, and their rivers. It attains the length of 20 or 25 ft., and has been known to weigh nearly 3,000 lbs. It enters the rivers in winter, while they are still covered with ice. Great part of the caviare of commerce is made from it, and much isinglass, which is merely the air-bladder washed, cut into strips and dried. The STERLET (*A. ruthenus*) is a comparatively small species, only about 3 ft. in length, found in the same regions, and particularly esteemed for the delicacy of its flesh, and of the caviare obtained from it. There are several other European and Asiatic species; and some of the North American rivers and lakes abound at certain seasons in species of sturgeon which are peculiar to them.—Sturgeons spawn in fresh water, but the young are seldom seen there, and are supposed to descend very early to the sea.

STURGES, JONATHAN, 1802-74; b. Conn., 1821; became a clerk in a New York mercantile firm, of which he became the senior partner in 1836, and with which he remained until 1868, when he retired with large wealth. He was noted for his support of the course of the government during the war, and for his activity in the cause of reform in city government, as well as for his liberal contributions for benevolent purposes.

STURGIS, SAMUEL DAVIS, b. Penn., 1822; graduate of West Point, 1846; served through the Mexican war; taken prisoner during the operations before Buena Vista; exchanged after a short confinement. He was on duty in California, New Mexico, and the w. frontier; capt., 1855. In the war of the rebellion he was obliged to abandon fort Smith, Arkansas (his officers having resigned to join the confederate army), taking with him his command and saving the government property. As maj. 4th cavalry, 1861, he served under Lyon, and succeeded to his command at Wilson's creek. In 1862 he was assigned to the command of the fortifications at Washington. He was prominent at South mountain, Antietam, Fredericksburg, and in the operations in Kentucky and Ohio, 1863-64, joining in the expedition against gen. Forrest; col. 7th cavalry, 1869; maj.-gen., 1865.

STURT, Sir CHARLES, 1806-69; b. England; entered the British army, and in 1825 was stationed in New South Wales, then holding the rank of capt. In 1828 he headed an exploring expedition which penetrated the interior of Australia and discovered the Macquarie, Castlereagh, and Darling rivers, and in 1830, the Murray river, which he descended to lake Alexandrina. Another expedition in 1844 reached the desert in the center of the continent. For these explorations he was honored with high colonial positions and on his return to England was knighted. He published two books describing his explorations.

STURTEVANT, JULIAN M., D.D., b. Conn. 1805; became professor of mathematics in Illinois college, and in 1844 was elected its president, still retaining the professorship. He published a lecture on *The Present Attitude of England toward the United States*, and has contributed to the *New Englander*, *Biblical Repository*, and other religious periodicals. He is original and vigorous as a thinker.

STUTSMAN, a co. in n. Dakota, drained by the Dakota river and Pine Stem creek; 2,304 sq. m.; pop. '80, 1007—694 of American birth, 3 colored. It is intersected by the Northern Pacific railroad. It contains the fort Seward military reservation. The surface in the vicinity of its co. seat is much diversified, in other portions stretching into level fertile prairies for miles on either side of the railroad track. Co. seat, Jamestown.

STUTTGART, the royal residence and metropolis of Würtemberg, is beautifully situated in a widening of the Nesenbach valley, the hills forming a semicircle of eminences clothed with vineyards, orchards, and gardens. The basin in which Stuttgart nestles is 897 ft. above the sea-level, and enjoys a mild and healthy climate.

Except the very oldest part of the city, the streets are broad, and the buildings handsome. The schloss, or palace, is a fine modern building. The royal park and gardens extend from the n.e. side of the palace for 2 m. in the direction of Canstatt, have an area of 560 acres, are adorned by fine groups of trees, and intersected by shady avenues, in which all classes may freely walk. The cathedral, built in the 15th c., was gifted by the king, in 1852, with several beautiful painted windows. Other principal buildings are the royal theater, public library, mint, museum of art, polytechnic school, erected in 1860-65, the royal stables for 300 horses, etc. A fine statue of Schiller has been erected in the palace place. The royal library contains 300,000 volumes, 3,600 MSS., 9,000 Bibles in 80 languages, and 2,400 specimens of early printing.

Stuttgart has many benevolent institutions and societies. There is direct railway communication with the leading cities of Germany, Switzerland, France, Belgium, and the Netherlands. Pop. in 1871, 91,623; of whom 78,624 were Protestants, 10,708 Roman Catholics, and 1817 Jews; in 1875, 107,273. Since 1866, and especially since the Franco-Prussian war, trade has increased in a remarkable degree. The principal industries are the manufacture of cotton and half-wool fabrics, iron and tin work, gold and silver articles, chemicals, tobacco, beer-brewing, etc. The export of Stuttgart manufactures to North America alone, averaged in late years 4,000,000 to 5,000,000 thalers. Stuttgart has a high position in the book-trade, and is the place of meeting of the booksellers' union of southern Germany. Stuttgart was the birth-place of Hegel;

here, also, Schiller's youth was spent. The name of the city occurs for the first time in 1229. It was besieged by king Rudolph of Hapsburg, 1286-87, and appears then to have been a place of strength. Between 1634-38, nearly 9,000 people died of the plague; and during the wars of Louis XIV., Stuttgart was thrice taken; and again in 1796, 1800, and 1801.

STUYVESANT, PETER, 1602-82, b. Holland; in early manhood entered the military service of the Dutch in the West Indies, and in 1634 was made director of the colony of Curacao. In 1647 the Dutch West India company appointed him director-general of their American colonies. He soon gained the confidence of the colonists, and reconciled the Indian tribes who had been made hostile by former unjust treatment. He also succeeded in arranging with the English commissioners, in 1650, the boundaries between their respective territories. A convention of delegated colonists in 1653 demanded for the people, among other things, a confirming voice in the appointment of local officers. Stuyvesant, with characteristic boldness, ordered them to disperse forthwith, claiming that his authority was not from the people, but from God and the Dutch West India company. The people submitted, but with mingled feelings of chagrin and discontent. The protracted contentions of the Dutch and the Swedes, dwelling near the Delaware river, about governmental jurisdiction, became more critical in 1654 when the Swedish governor seized the fort built by the Dutch, where Newcastle now stands. To end this trouble, Stuyvesant with 600 men sailed up the Delaware, re-captured the fort, and established the Dutch authority over the entire territory. After ten years of undisturbed quiet, in 1664 an English vessel arrived with an armed force under col. Nicholls, who demanded a surrender of the government, on the ground that the whole territory was given by royal charter to the duke of York. Stuyvesant at first refused, but finding the people anxious to exchange rulers, he yielded to the English demand. Thus abruptly terminated the Dutch control over the New Netherlands, and both the town and the territory was thenceforth called New York. Stuyvesant reported personally to the authorities in Holland, but soon returned to New York for the remainder of his life. He cultivated an extensive farm called the Bouwerij, giving its name to one of the busy streets of the city. A pear tree in his garden, which he brought from Holland, bore fruit more than 200 years. As an interesting relic of the past and of the man so highly and so justly honored, the city authorities for many years protected this pear tree by a tall iron railing. Stuyvesant died in 1682, aged 80 years. He was buried where St. Mark's church now stands, and the elaborately inscribed stone that covered his grave is built into the eastern wall of the church.

STYE, or **STY**, is the popular name for a minute boil occurring at the edge of the eyelid, and known to surgeons under the term *hordeolum*. It begins as a small, red, tense swelling, accompanied with considerable itching, and a feeling of stiffness. As the inflammation goes on, the lid may become so swollen as to keep the eye closed. In a few days, matter forms, a white point appears at the apex of the swelling; and when the cuticle gives way, pus and a small slough of connective tissue escape, after which there is a general remission of the symptoms, and the eyelid soon resumes its natural state.

This common affection is chiefly confined to scrofulous and delicate children, but it is sometimes observed in persons of more advanced age. The best local treatment consists in the application of warm-water dressings with lint and oiled silk; and if any hardness remains after the discharge of the matter, dilute nitrate of mercury ointment may be applied. The sty should never be rubbed (notwithstanding the common prejudice in favor of rubbing it with a gold ring), nor, in general, is it necessary to puncture it. To prevent the recurrence of these little boils, attention should be paid to the diet, which should be abundant and nourishing, to the state of the bowels, and to the general health; and tonics may usually be prescribed with advantage. The old form of the word was *stiun*. See Holland's *Plinie*, book xxviii, ch. xi.

STYLE, OLD AND NEW. NEW CALENDAR.

STYLITÉS. See **PILLAR SAINTS**.

STYLOBATE, the substructure of a temple beneath the columns. It is sometimes continuous all round the peristyle in the form of three high steps; sometimes it resembles a continuous pedestal along each side, with flights of steps at either end.

STYPTICS (Gr. *styptikos*, astringent) are agents employed in surgery for the purpose of checking the flow of blood by application to the bleeding orifice or surface. See **BLEEDING**.

STYRAX. See **STORAX**, *ante*.

STYRIA (Ger. *Steiermark*), a duchy forming one of the German crown-lands of Austria, is bounded on the n. by upper and lower Austria, e. by Hungary and Croatia, s. and w. by Carinthia, Carinthia, and Salzburg. Its area is 8,671 English sq.m., and pop. '70, 1,137,990, who are partly of German and partly of Slavic origin. Styria is a mountainous country, being traversed in the w. and center by branches of the Noric Alps, which spread out into numerous ramifications: while the southern portion between the Drave

and the Save is occupied by branches of the Carnic Alps. The climate of Styria, like that of most mountainous countries, is variable, but is generally raw and cold in the northern and more mountainous portion, and mild in the south. But in spite of its physical character, agriculture is so zealously prosecuted that $\frac{2}{3}$ of the country are under cultivation, producing rye, wheat, oats, and maize. Vines are largely cultivated in various parts, and orchards are numerous. The chief wealth of the country, however, lies in its mineral products, which include, besides immense quantities of iron, lead, copper, gold, silver, marble, limestone, and slate, with abundance of salt and coal. The chief industries are thus necessarily in connection with the production of iron and steel, and their manufacture into articles of such excellent quality as to be in great demand in other countries. There are also manufactures of brass and lead articles, earthenware, paper, tobacco, glass, white-lead, copper hammers, and of cotton, linen, cloth, etc. Styria was anciently divided between Noricum and Pannonia, and has generally followed the fortunes of the two provinces of Upper and Lower Austria.

STYX (Gr. *stug-*, to hate, abhor), a water-fall in Greece, near the town of Nonaeris, in the n.e. of Arcadia, descends perpendicularly over lofty and precipitous rocks, and forms a small torrent, which falls into the Crathis. The scenery around it is weird and desolate, so that the Greeks regarded the Styx with superstitious awe; the water being supposed to be poisonous, and to break every vessel into which it was put, except those made of the hoof of a horse or an ass. It was reported that Alexander the great had been poisoned by it. It is now called *ta Mavraneria* (the black waters), and also *ta Drakoneria* (the terrible waters), the belief in its poisonous qualities still surviving.—In mythology the Styx was a river of Hades, round which it flowed seven times, and over which Charon (q.v.) conveyed the shades of the departed. As a goddess Styx was the daughter of Oceanus and Tethys, dwelling in a grotto at the entrance of Hades. She was the confirmer of the most solemn oaths of the gods.

SUABIA. See **SWABIA**.

SUAKIN, a sea-port belonging to Turkey, on a small rocky island in the Red sea, off the w. coast of Africa, but near the shore, in lat. about 19° 10' north. It has a good harbor, and a considerable trade, especially in gums; and it is a station for pilgrims passing to and from Africa. Population estimated at 8,000.

SUARES, FRANCISCO, the most celebrated of the modern scholastic and polemical divines of the Roman Catholic church, was born at Granada in 1548. His early studies were singularly unpromising; and it is remarkable, in the history of a man afterward so eminent, that it was not without great difficulty, and after repeated trials, that he obtained admission into the society of the Jesuits. His later career, however, was brilliant, quite in proportion to the dullness of his first beginnings; and he taught philosophy and theology with remarkable success, first at Alcalá, and afterward at Salamanca, Rome, and Coimbra. The accounts given of his habits of application to study are almost beyond belief. He is said to have habitually devoted seventeen hours a day to study. Of his power of memory, the marvels related are scarcely less prodigious. He is said to have been able to repeat at will any portion of the whole 23 folio volumes of his own works, even to the quotations from the fathers and other theological writers with which they abound. Suarez may truly be described as the ablest and greatest of the modern scholastics; but in his works scholasticism appears in its best form; for although they abound in discussions uninteresting, and indeed unintelligible, to persons unacquainted with scholastic terminology, yet they may also be truly said on each subject to exhaust the whole of the learning, ancient and modern, which existed relating to that subject at the date of their publication. On the philosophy of the ancients, Suarez is especially copious and accurate; and of most of the modern German philosophy we may find the germ in the pages which he devotes to the account of the opinions of the ancients.

In the scholastic controversies on grace and free will, Suarez was strongly opposed to the Thomistic doctrine; but he also rejected the opposite system of Molina. See **MOLINISM**. The scheme of reconciling the freedom of the will with the efficacy of grace, and of saving at the same time, the doctrine of "special election," devised by Suarez, is called *congruism*, and is explained under the head **MOLINA**. The works of Suarez are entirely theological, or ascetic, and were printed in 23 volumes folio at Lyons, Mainz, and Venice. An edition in 28 volumes 4to was completed at Paris in 1861. His treatise *De Legibus* is much esteemed, and has been reprinted in England. Suarez died at Lisbon in 1617.—See Des Champs, *Vie de Suarez* (4to, Perpignan, 1671).

SÛ BAHDÂR was, under the mogul government, the title of a governor of a province. It now designates a native officer, holding a rank equivalent to that of captain under the European officers.

SUBALTERN, in the army, or rather in a regiment, is a company officer below the rank of captain; i.e., a lieut. or sublieut.

SUBDOMINANT, in music, the fifth below the tonic; the note whose dominant is the tonic. Thus F is the subdominant of C, and C of G. One of the keys most nearly related to any key is its subdominant; and the easiest of all modulations is that from a key to its subdominant, which is effected by adding the dominant seventh to the com-

mon chord, and the resolution of this chord is the common chord of the subdominant; e.g., in modulating from the key of C to the key of its subdominant F, we have

See DOMINANT.

SUBIACO (anc. *Sublaqueum*), a city of the province of Rome, on a hill by the Teverone, 30 m. from Rome. Subiaco possesses a fine cathedral, and many monuments of antiquity. There was a famous Benedictine monastery in Subiaco, and here, in the 15th c., one of the earliest printing-presses in Italy was established. Pop. 7,000.

SUBJECT. See OBJECT.

SUB-KINGDOMS, ANIMAL, a term applied to the great primary divisions of the animal world. The sub-kingdoms are also named "morphological types," and this latter term serves to indicate their constitution more definitely than the name "sub-kingdom." As an example of the manner in which a "sub-kingdom" of animals is constituted, we may select that of the *Annulosa* or *Articulata*, a group of animals which was clearly defined by Cuvier himself, and which has remained since his day, with few alterations, as one of the most distinctive groups of the animal creation. A lobster may be selected as a typical example of this group. In the detailed examination of this animal, we may note that the jointed nature of the tail is perceptible in the fore part of the body, notwithstanding that the latter region consists apparently of a single piece. A further examination of the lobster's body would reveal the fact that each joint and its appendages—the latter being "paired"—agrees in essential or fundamental structure with every other joint of the body. The investigation of the plan of structure of the lobster's frame would show a very typical arrangement of parts. The *heart* lies dorsally, or on the back. The *digestive system* occupies a median position; and the *nervous system* lies ventrally, or on the floor of the body. The nerve-axis of the lobster further consists, typically, of a double chain of nervous masses (or *ganglia*) united by nervous cords, and from which branches proceed to the various parts of the body. The ideas we may gain regarding the *general type of structure* of the lobster's body, or plan on which that body is built up, may be thus summarized: (1.) The body is jointed; (2) the joints and their appendages are fundamentally similar or homologous; (3) the heart lies dorsally, the nervous system ventrally, while the digestive system occupies the median position; (4) the appendages are in pairs. Now, if we examine the body of any insect, we shall find it to essentially resemble that of the lobster in the general arrangement of its parts. The body of a spider or a scorpion exhibits a similar disposition of organs to that of the lobster, and shows a fundamentally similar structure beneath variations in appearance and form; and a centipede's body would be found to be also constructed on the lobster-type. The barnacles, water-fleas, crabs, and a whole host of animals more or less nearly allied to the lobster, and belonging to the lobster's class (that of the *Crustacea*), exhibit a near relationship with the typical animal; while worms generally (leeches, earth worms, etc.) would present a fundamental similarity in their characters to those described as existing in the lobster. We thus discover uniformity of type beneath variations in form and appearance, and it is exactly this uniformity or broad structural likeness between apparently different animals which enables us to group them together to form "sub-kingdoms" or "types." A sub-kingdom or type of animals may therefore be defined as consisting of a *number of animals whose bodies are constructed on the same fundamental plan*. Lobsters, crabs, barnacles, etc., insects, spiders, scorpions, centipedes, and worms thus form the "sub-kingdom" *Annulosa*, on account of their agreement in fundamental structure, and in the essential characters just described as being typically exhibited by the lobster. The animal world is thus divided into five or six sub-kingdoms. Between some of these groups recent research—altogether unfavorable to the construction of defined sub-kingdoms or types—has demonstrated connecting links to exist. But by the great majority of zoologists, the following divisions are recognized:

- I. PROTOZOA—Ex.: Sponges, infusoria, amœbæ, and other animalcular forms.
- II. COELENTERATA—Ex.: Sea-anemones, corals, zoophytes, jelly-fishes, etc.
- III. ECHINOZOA—Ex.: Sea-urchins, star fishes, crinoids, sea-cucumbers, tape-worms, flukes, etc.
- IV. ANNULOSA—Ex.: Worms, insects, centipedes, spiders, crustacea.
- V. MOLLUSCA—Ex.: Sea-mats, sea-squirrels, lamp-shells, shell-fish, cuttle-fishes.
- VI. VERTEBRATA—Ex.: Fishes, amphibia, reptiles, birds, mammals.

SUBLAPSARIAN (Lat. *sub-lapsus*, after the fall), the name given to one section of the school of divines, who maintain the doctrine of absolute decrees of election and reprobation. It is possible to conceive God making such a decree in two different ways, either on the hypothesis of his foresight of the fall of Adam, and thus of original sin, or independently of such foresight on his part, and without any reference to such foresight, and entirely out of his own free will and determination. The sublapsarian system supposes the former; and thus refers the eternal election or reprobation of men by God to his foreseeing that all men would fall in Adam, and thus would deserve eternal reprobation. Out of the entire mass of mankind thus fallen, he freely pre-lects some

to life, and equally freely predooms others to death. This distinction is not confined to the Calvinistic schools; it is also found among the Roman Catholics. See SUPRALAPSARIAN.

SUB-LIEUTENANT is the junior combatant commissioned officer in the royal navy. When a midshipman has served six years, and can pass in seamanship and certain other subjects, he becomes a sub-lieutenant, and is eligible for promotion to lieutenant on opportunity occurring. The pay of a sub-lieutenant is £91 5s. a year, and the half-pay, £45 12s. 6d. An officer usually serves but a short time in this rank; and, if not promoted earlier, he must retire at 40 years of age. Until within a few years, the sub-lieutenant was called a mate (q.v.). The establishment is in process of reduction to 250 as a fixed number. In the army cornets and ensigns are now sub-lieutenants.

SUBLIMATION is a chemical process similar to distillation, but differing from it in the nature of the substances to which it is applied. While in distillation *liquids* are converted by the agency of heat into vapor, which is condensed in the liquid form usually by the cooling action of water; in sublimation, *solid bodies* are reduced by heat to the state of vapor, which reassumes the solid form on cooling. Sublimation is usually conducted in a single vessel of glass or iron, the product being deposited in the upper part of it in a solid state, while the impure residue remains at the bottom; but in the case of sulphur, the vapor is condensed on the walls of a large chamber. Iodine affords a good example of sublimation. On gently heating the lower part of a Florence flask containing a little of this substance, a purple vapor rises, which almost immediately condenses in small brilliant dark purple crystals in the upper parts of the flask, while any impurity that may be present remains at the bottom. Among the substances obtained by this process, and employed in the pharmacopœia, are arsenious acid, benzoic acid, corrosive sublimate, and sublimed sulphur.

SUBLIME. Objects indicating great power, vast expanse, or lofty elevation, excite in the beholder a feeling of pleasurable elation; and the name "sublime" is applied both to the objects and to the feeling.

The precise quality in things that arouse this mode of pleasurable excitement has been variously assigned. According to Burke, *terror* is, in all cases whatsoever, either more openly or more latently the ruling principle, or, at all events, one of the chief sources of sublimity; Blair suggested that *mighty power or force* is the cause; Payne Knight ascribed it to *mental energy*; Kaimes considers it due to *height or elevation*; Dugald Stewart, in an elaborate essay, affirms that *elevation* is the leading characteristic, and that expanse and power are sublime by suggesting or implying great height; Sir W. Hamilton says that sublimity requires *magnitude* as its condition, and exists in three forms—space, time, and power.

The feeling itself has also been described variously. If this could be fixed, we should have a key to the objective quality. Longinus characterized it, in reference to literary composition, as "filling the reader with a glorying and a sense of inward greatness." Some would call it a "sense of security" in circumstances of terror or danger. Hamilton describes it as "a mingled feeling of pleasure and pain—pleasure in the consciousness of the strong energy, pain in the consciousness that this energy is vain." The connection with the sentiment of power is generally admitted; but as the comparison of the object with self suggests our own littleness at the same time, there may be a doubt as to whether the emotion is due to the power, to the littleness, or to the combination of both.

Referring to the generic sentiment of power, which is evidently at the foundation, we find that the feeling of superior might in ourselves is cheering, elating, stimulating; and that the sense of littleness or inferiority is a depressing and enfeebling state of mind, a state of pure pain, redeemable in certain circumstances by other feelings, as when our inferiority is only in the comparison with an object of love or veneration, or when it is the condition of some compensating superiority—"the courtier stoops to rise." The presumption, therefore, is that the elation of the sublime is connected with the notion of power. It may be felt although the power is not actually possessed, but imagined, borrowed, or conceived, through a sort of sympathy with the *appearances* of great power or might. If this account of the feeling be correct, power must be a principal quality in its objects; and if with this we combine voluminous sensation (and the corresponding ideas, vastness of expanse and greatness of time), we shall probably be able to explain the sublime in all its forms.

SUBMARINE FORESTS occur at several places around the shores of Britain and Ireland. They consist of beds of impure peat, containing the stools of trees which occupy the sites on which they grew; but by change of level, the ancient forest surfaces are now covered by the tide even at low water. No kind of tree has been found in these forests which does not exist at the present day in the country, and the underwood and herbaceous plants, so far as determined, agree specifically with those found now in similar localities. Submarine forests belong to the recent or quaternary period, and occur above the boulder clay.

SUBMARINE NAVIGATION. When the diving-bell (q.v.) had shown that air for respiration can be supplied to persons placed in adequately arranged vessels under

water, ingenious men began to speculate on the possibility of navigating closed ships or boats in similarly exceptional circumstances. Cornelius Drebbel made a vessel to be rowed under water in the time of James I. In 1774 an inventor named Day lost his life during an experimental descent in Plymouth sound, in a vessel of about 50 tons burden. Mr. Bushnell, of Connecticut, in 1775, and Robert Fulton, about 1796, contrived submarine vessels, intended to be used in warfare. The vessel patented in 1859 by Mr. Delaney, of Chicago, was egg-shaped in transverse section, and diminished nearly to a point at each end. It had two iron tanks in the interior; one had air forced into it by an air-pump; the second contained water. The engineer of the boat, by pumping water into or out of the second tank, through the action of the air in the first, could raise or lower the boat to different depths in the water.

SUBMAXILLARY GANGLION, one of the four sympathetic ganglia lying in the cephalic region, sometimes called cranial ganglia; but the latter term is rather misleading, as none of the ganglia are within the cranial cavity. The submaxillary ganglion is situated above the deep portion of the submaxillary gland. See **SALIVARY GLANDS**, *ante*. It is connected by filaments with the lower border of the gustatory nerve (nerve of taste, supplying the tongue). It also receives motor filaments from the chorda tympani nerve, a branch of the facial. It is small, rounded, and of a reddish-gray color; its filaments of distribution, five or six in number, arise from the lower part of the ganglion, and supply the mucous membrane of the mouth and Wharton's duct, some being lost in the submaxillary gland.

SUBORDINARY, or **SUBORDINATE ORDINARY**, in heraldry, a name given to a certain class of charges mostly formed of straight or curved lines. Heralds vary a little in their enumeration, but the following are generally held to come within this category: the bordure, the orle, the tressure, the flaunch, the pile, the pall, the quarter, the canton, the gyron, the fret, the inescutcheon, the lozenge, the fusil, and the mascle. See these heads; also **ORDINARIES**.

SUBORNATION or **PERJURY** is the offense of procuring another to take such a false oath as constitutes perjury (q.v.) in that other. It is a misdemeanor, punishable anciently by death; afterward banishment, or cutting out of the tongue; then forfeiture of goods; and latterly, as at present, by fine and imprisonment.

SUBPENA, in English law practice, means the writ or process by which the attendance of a witness in a court of justice is compelled. It is a writ in the queen's name, commanding him to lay aside his business and all excuses, and attend at the time and place indicated, under a penalty of £100. If the witness is required to produce a document, the writ is called a *subpœna duces tecum*. If the witness do not attend, and has not a good legal excuse, such as dangerous illness, he may be sued in an action of damages or committed to prison.

SUBROGATION, in law, the substitution of another person in the place of the original creditor. The person thus taking the creditor's place succeeds to all the rights of the latter. Subrogation is taken from the Roman law, and belongs to equity rather than to common law jurisprudence. It may be conventional, where it takes place from the agreement of the parties; or may result from the action of the law, as where it takes place for the benefit of co-promisors and for the benefit of sureties against their principals. When a second mortgagee pays the first mortgagee's claim, he at once becomes the equitable assignee of the first and can compel actual assignment, and so in all cases where a prior creditor is paid by a subsequent one. If an entire debt be paid by one of several joint debtors, he is entitled to contribution from the others and subrogation takes place.

SUE ROSA, "under the rose"—i.e., between ourselves, or in secrecy. It was customary among the ancient Germans, on occasions of festivity, to suspend a rose from the ceiling above the table, as a symbol that whatever was said during the feast by those present would be afterward forgotten, or at least be kept as a secret among themselves.

SUBSCRIPTION, in law, a written contract by which a person agrees to contribute a sum of money for a specified purpose; as a subscription for a college or a newspaper. If the contract be legal and grounded on good consideration a subscriber may be sued for his subscription as soon as the condition upon which he made the promise is fulfilled. It has even been held that subscribers for a common purpose may be regarded as contractors with each other, and the consideration of each subscription the promises of all the other subscribers, so that each subscriber may be sued by all the others. This seems to be scarcely tenable, and it is customary to make subscriptions payable to a treasurer. Wherever action has been taken upon the subscription by the expenditure of moneys or otherwise, before notice received of the withdrawal of a subscription, there is a consideration sufficient to support the promise, which may then be enforced.

SUBSIDIES, a term in politics, used in two different senses: 1. It is applied in English political history to taxes levied not immediately on property, but on persons, in respect of their reputed estates in lands or goods; or customs imposed on any of the staple commodities in addition to the *costuma magna et antiqua*. Thus 30,000 sacks of wool were granted to Edward III. in 1340, in aid of the war with France. Subsidies were granted on various occasions to James I. and Charles II. 2. The same word is

used to denote money paid by one state to another, in order to procure a limited succor of auxiliary troops, ships of war, or provisions. In the time of the war with the revolutionists of France and Napoleon I., Great Britain furnished subsidies to foreign powers to a large extent, in order to engage them to resist the progress of the French. In questions regarding subsidies, it is held that the state furnishing the succor does not thereby become the enemy of the opposite belligerent; it may remain neutral in all respects, except as regards the auxiliary forces supplied. Such, for example, was long the attitude maintained by the confederate cantons of Switzerland: while granting troops to the various European powers, they were in the habit, at the same time, of preserving a rigorous neutrality. The service of Swiss regiments abroad is no longer sanctioned. The federal constitution of Switzerland, of Sept. 12, 1848, prohibited the conclusion of military capitulations; and on July 30, 1859, a proclamation was issued by the federal council, forbidding any Swiss subjects from taking service under a foreign power, without the authorization of the council.

SUBSTANCE, a word connected with certain discussions in logic and metaphysics. Substance is correlative with quality or attribute. Every substance must have attributes, and every attribute must be the attribute of some substance. The substance gold has the attributes weight, color, etc. But as every power or property of a thing, every way that the thing affects us, may be called an attribute or quality, if all the attributes are counted off, there is nothing left; and the question then arises: What is the *substance*? To avoid this seeming inconsistency, it was assumed that everything whatsoever possesses, besides its attributes, an unknown substratum that they rest upon, or inhere in—a mystical and inscrutable bond, that holds the attributes together, without being itself an attribute. This gratuitous assumption of what is, after all, a nonentity, was repudiated by Locke and others, who found a meaning for substance without departing from the knowable. Every object has some *essential* or *fundamental* quality, which being present, it preserves its identity; and which being removed, it is no longer the same object, but another. Thus the substance of body or matter is not the remnant after all the qualities are subtracted; it is the two fundamental and inerasable qualities, extension and resistance; size, shape, color, heat, odor, etc., may all be varied; but so long as extension and resistance in any degree are found, we have a piece of matter. On the same view, the substance of mind is whatever we regard as its fundamental essence, or distinguishing marks. We may adopt feeling, or volition, or intellect, or require a share of all three, according to our mode of defining the mind. It would, then, be a mere confusion of language to talk of feeling, volition, and intellect as *inhering* in mind; they *are* mind, and there is nothing besides.

Notwithstanding the obviousness of this explanation, the employment of the words substance and attribute has led to such an inveterate demand for something that shall underlie all attributes—a substance of body, and a substance of mind—distinct from anything meant by the names, that many philosophers have considered it necessary to preserve the phantom as a thing of belief, if not of knowledge. The doctrine of an unknowable substance in the abstract very early allied itself with the popular theory of the perception of a material world (see PERCEPTION), and the same arguments are good, for or against both. Other names for expressing the same contrast are *noumenon* and *phenomenon*. The phenomenon is what shows itself to our senses, or is conceived by our intelligence—the qualities of extension and resistance in body; and of feeling, etc., in mind. The noumenon is something apart and beyond, something inconceivable and unknowable, but which, say some, we are instinctively led to believe in. Thus, in the great question above alluded to—the belief of an independent material world—the phenomenal manifestations are inextricably involved with our mental powers of conceiving, and would vary, if these were to vary; consequently, they cannot be the absolute, independent, self-existent reality; which drives one school of philosophy upon the expedient of believing in such a reality, although it must be for ever incomprehensible to us.

SUBSTITUTE, MILITARY. In nations where conscription is resorted to for the supply of soldiers for the army, the lot often falls on those unwilling to serve in person. In such a case the state sometimes agrees to accept the services of a substitute who is of equally good physique. Unless the levy be very extensive, or the term of military service very long, substitutes are readily found among military men who have already served their prescribed period. Of course, the substitute must be paid for the risk he runs. His price depends, like all other saleable articles, on the demand and supply. Happily, in Great Britain, few of those now living have ever known when substitutes were necessary. It is, however, to be remembered that the act for a militia ballot hangs continually over us, and is only suspended by a special act of parliament from year to year.

SUBSTITUTION is one of the three principal methods employed in examining the chemical composition of organic bodies, and in tracing their relation to other compounds; the two other methods being those of *oxidation* and of *reduction*. Although the term is restricted to organic chemistry, the ordinary method of preparing insoluble inorganic compounds by double decomposition is in reality a case of substitution of one base or one acid for another. If, for instance, solutions of nitrate of lime and sulphate

of soda are mixed together, the resulting compounds are sulphate of lime and nitrate of soda, in which the lime is substituted for the soda, and the soda for the lime. In some cases an element may be replaced (or, more correctly, displaced) by a compound group; thus, cyanogen, C_2N , may take the place of oxygen, as, for example, in the reaction that ensues between hydrocyanic acid and red oxide of mercury, when cyanide of mercury and water are formed, as shown in the equation $H(C_2N) + HgO = Hg(C_2N) + HO$. Similarly, the groups NO_3 , SO_2 , and NH_2 may often be substituted for hydrogen. In various organic bodies, one or more atoms of hydrogen may be displaced by one or more atoms of chlorine, a fact which was originally observed by Gay-Lussac in noticing the action of chlorine on wax. The new product thus formed is almost always analogous in its nature to the compound from which it is produced; thus, according as the substance acted on by the chlorine is an acid or a base, the resulting product is an acid or a base, and the number of atoms is always the same in the original substance and the product. The following examples will elucidate the above remarks: If acetic acid, $C_4H_4O_4$, be exposed to the action of chlorine, we obtain, according to the duration and modifications of the action, the two compounds, monochloroacetic acid, $C_4H_3ClO_4$, and trichloroacetic acid, $C_4HCl_3O_4$, in the former of which, one atom, and in the latter, three atoms of hydrogen, are displaced by a corresponding number of atoms of chlorine. Hydrochloric ether, C_4H_5Cl , may be made to yield the following succession of compounds, in which a gradually increasing amount of the hydrogen is displaced by chlorine, until, in the final result, the hydrogen has altogether disappeared. The consecutive compounds thus resulting from hydrochloric ether, C_4H_5Cl , are (1) chlorinated ether, $C_4(H_4Cl)Cl$; (2) dichlorinated ether, $C_4(H_3Cl_2)Cl$; (3) trichlorinated ether, $C_4(H_2Cl_3)Cl$; (4) tetrachlorinated ether, $C_4(HCl_4)Cl$; and (5) sesquichloride of carbon, $C_4(Cl_5)Cl$. "The chlorine," says prof. Miller, "appears to have taken the place of hydrogen in the group without disturbing the relative position of the other elements which enter into its formation; just as a brick in an edifice may be conceived to admit of being removed, while its place is supplied by a block of wood or of stone, without altering the form or symmetry of the building." Substitutions of bromine and iodine for hydrogen may be effected in the same way as has been shown to occur in the case of chlorine. The study of the artificial formation of organic bases has led to the discovery of many remarkable instances of substitution products. If, for example, bromide of ethyl, C_4H_5Br , is heated in a sealed tube with a solution of ammonia in alcohol, hydrobromate of ethylia (or ethylamine) is formed, and on distilling this vapor with hydrate of potash, one of the products is a new base, ethylia, C_4H_7N , which may be regarded as ammonia, NH_3 , in which one atom of hydrogen has been displaced by one atom of ethyl, C_2H_5 . By a similar proceeding, we may successively displace the second and the third atoms of the hydrogen in the ammonia; and we thus obtain two more complex bases, diethylia, C_6H_9N , and triethylia, $C_8H_{11}N$.

SUBTRACTION, one of the four fundamental processes of arithmetic, is the diminution of a quantity by the removal of a certain portion of it. It is consequently the reverse of *addition*, and determines how much of any quantity remains after a certain quantity has been taken from it. In cases where the digits of the number to be subtracted are greater than the corresponding ones of the number to be diminished, two methods of operation may be adopted.

(1)	(2)	(3)
7324	7 (13) (12) 4	6 (13) (12) 4
1843	(2) (9) 4 2	1 8 4 2
5482	5 4 8 2	5 4 8 2

For example, in subtracting 1842 from 7324, the numbers are written as in form (1). The method of operation usually followed is to make an addition mentally to the upper figure when necessary, and then compensate for this by an equivalent addition to the next under figure, as represented in form (2). Thus 10 "tens" are added to 2 "tens," to enable 4 "tens" to be subtracted; and this addition is compensated for by an equal increase of the under line by 1 "hundred," through the change of 8 "hundreds" into 9 "hundreds." The more simple and directly intelligible plan, shown in form (3), is to borrow a unit of the next higher degree in the upper line, care being taken to remember in the partial subtraction immediately succeeding, that the upper digit must be considered as less by unity than it appears.

SUBWAYS. The system of engineering *beneath* the public streets has not by any means yet reached its full development. Subways for foot passengers are occasionally constructed in connection with railway termini: one such connects the Bishopsgate street station of the Metropolitan railway with the Liverpool street station of the Great Eastern; another connects two Victoria stations at Pimlico, belonging to different lines and companies. The *Tower Subway* is a remarkable instance of a passage under the Thames for foot-passengers. The Metropolitan or underground railway, opened in 1863, was the first example of its kind; the passengers going down stairs from the side-pavements to stations underneath the carriage-way. The pneumatic propulsion of mail-bags (see PNEUMATIC DISPATCH) has given rise to projects for a similar mode of propelling railway trains beneath streets and roads. One such, the Waterloo and Whitehall railway,

was commenced about 1865, to pass under the Thames; want of funds led to its abandonment after shafts had been sunk. The term *subways* is usually applied, not to such tunneled passages for traveling, but to roomy archways that will contain sewer-pipes, water-pipes, and gas-pipes. It has been long considered a defective system that whenever such pipes need repair, the surface of the street has to be broken up to get at them, thereby causing great expense and great interruption to traffic. When the metropolitan board of works commenced their series of improvements, they resolved on the trial of subways for this useful purpose. They began with a new street, extending from Covent Garden market to St. Martin's lane, opened in 1861. Underneath the carriage-way of this street, there is a subway, a central arched passage or tunnel 12 ft. wide by 6½ ft. high; with arched side-openings for house service-pipes connected with the cellars of the several dwellings. In this subway are water-pipes, gas-pipes, and electro-telegraphic wires, all easy of access by side entrances to the subway, of sufficient size to admit workmen, pipes, etc. In this instance, the main sewer is not in the subway itself, but underneath it, provided with man-holes, gullies, ventilating shafts, etc. A second example is afforded by Southwark street, lately formed from Blackfriars road to the southern foot of London bridge. Underneath this street extends a subway, excellently planned for the purposes above mentioned. Two street lamp-posts, of unusually elegant design, one at each end of the street, act as ventilating shafts for the subway, and there are other ventilators along the route, besides side entrances for workmen. A curious proof has been furnished, however, of the anomalies which so frequently mar our public works. In 1865, a gas company broke up the roadway, and broke through the well-built crown of the arch of the subway, to get at their gas-pipes for purposes of repair or adjustment. It was found, on investigation, that no one had power to prevent them. The act empowered the metropolitan board of works to make a subway for the use of gas companies, water companies etc.; the gas company, on the other hand, were empowered by *their* act to break up the public roadways to get at their pipes; the board could not compel the company to adopt the new plan, because the powers were only permissive, not obligatory. The water companies and gas companies fear incurring additional expense; and there is known to be a difference of opinion among engineers concerning the danger from leakage and explosion when the two sets of pipes are inclosed in the same archway.

The subway system, after overcoming these and other difficulties, has made a great advance within a recent period. Queen Victoria street, and several other new streets, have been provided with subways similar to that under Southwark street. The Victoria or northern Thames embankment presents some fine examples of subway engineering. Between the masonry of the river-wall and the former line of high water, there are no less than three tunnels or arched passages under the surface of the ground parallel to the course of the river. One is the metropolitan district railway; another is the low-level sewer of the Great Main Drainage system; while a third is a subway to contain gas and water-pipes, telegraph wires, etc. The most extraordinary plan, perhaps, ever seriously proposed in subway engineering is connected with the spot where Tottenham Court road, Euston road, and Hampstead road join. The Metropolitan railway is here flanked on either side by sewers; above it, but below the level of the street, are several gas and water pipes, drains, and ventilating shafts; while crossing immediately over the Metropolitan railway, at right angles, is the tube of the (still abortive, 1879) pneumatic dispatch (q.v.). Beneath all this is the section of another tunnel, intended to join the Midland and North-western railways with the South-eastern. Civil engineers and contractors are ready to grapple with the difficulties of this extraordinary work whenever financial circumstances are favorable.

SUCCESSION is a legal term used in Scotland, but not used technically in England, where the same subject is spoken of under the name of next of kin (q.v.), and descent; see also **INTESTACY**, **STATUTES OF DISTRIBUTIONS**, **EXECUTORS**, **ADMINISTRATOR**. In Scotland the term is used to denote the taking of property by one party in place of another. Where the devolution takes place in consequence of a conveyance from the proprietor, the acquirer is termed a singular successor, as the conveyance is the single title under which he acquires. Where, however, the person dies intestate, his heir succeeds to the whole of the heritage, and is called the universal successor. Where no will or disposition by the owner is executed, the law makes a disposition for him, and distributes the property according to certain rules of relationship by blood. 1. In the case of heritable succession, primogeniture (q.v.) is the rule, the eldest son and his issue taking the property; and after that stock is exhausted, the next eldest son; and so on. When males fail, then the succession opens to the daughters, who take not in order of seniority, but all together, and are called heirs portioners (q.v.). When descendants fail, then the succession goes to collaterals; thus, brothers and sisters succeed first—the brothers according to a certain priority, and, failing them, the sisters all together as heirs-portioners. When the descendants and collaterals are exhausted, the succession then goes to ascendants (the mother, however, being entirely excluded), the father first, and then uncles and aunts, etc. In heritable succession, the right of representation exists, i.e., when an heir is dead, his children represent him, and take that share which, if alive, he would have taken. Brothers and sisters consanguinean, i.e., by the same

father, but not by the same mother, succeed after brothers and sisters german (i.e., by the same father and mother), before the remoter line of the full blood. The English law of descent or succession differs considerably from the above. See *INTESTACY*, and Paterson's *Comp. of English and Scotch Law* (2d ed.), s. 751, *et seq.*—2. As to succession in movables, or to the personal property of the intestate, see *KIN, NEXT OF*. There are taxes called succession duties, which are payable to the revenue on all property, real and personal, acquired by succession. The duty payable on lineal issue or lineal ancestors is 1 per cent; by brothers and sisters and their descendants, 3 per cent; and so on, the duty increasing as the relationship is more distant. The husband or wife of the proprietor is exempted from the duty.

SUCCESSION ACTS. From a comparatively early period in English history, parliament occasionally exercised the power of limiting or modifying the hereditary succession to the throne. The first instance of such interference occurred in the reign of Henry IV., who possessed himself of the crown, to the prejudice of the descendants of Lionel, duke of Clarence, second son of Edward III. Act 7 Henry IV. c. 2 confirmed the title of that monarch, and declared prince Henry heir-apparent of England and France, with remainders to Henry IV.'s other children. Parliamentary interposition was subsequently exercised in the case of Henry VII. and in regard to the immediate successors of Henry VIII. The respective rights of James I., Charles I., and Charles II. were acknowledged by parliament; and in the case of Charles II. the crown was held to have devolved on him immediately on the death of his father.

The revolution of 1688 was founded on the so-called abdication of the government by James II. See *ABDICACION*. The convention bestowed the crown on William and Mary for life, and regulated the claims of Anne. On the impending extinction of the Protestant descendants of Charles I., the crown was settled by 12 and 13 Will. III. c. 2, in the event of the death of William and Anne without issue, on the next Protestant line, according to the regular order of succession—viz., the descendants of the electress Sophia of Hanover, granddaughter of James I.; and it was at the same time enacted, that whoever should hereafter come to possession of the crown, should join the communion of the church of England as by law established. This is the latest parliamentary limitation of the crown; but the right of parliament to limit the succession has been secured by 6 Anne, c. 7, which attaches the penalties of treason to the "maliciously, advisedly, and directly" maintaining, by writing or printing, that the king and parliament cannot make laws to bind the succession to the crown, and the penalties of a *præmunire* (q.v.) to maintaining the same doctrine by preaching, teaching, or advised speaking.

SUCCESSION WARS were of frequent occurrence in Europe, between the middle of the 17th and the middle of the 18th centuries, on the occasion of the failure of a sovereign house. The most important of these wars was that of the Orleans succession to the Palatinate (1688-97), closed by the peace of Ryswick; of the Spanish succession (1700-13); of the Polish succession (1733-38), closed by the peace of Vienna; of the Austrian succession (1740-48); and of the Bavarian succession (1777-79), called, in ridicule, the potato-war. Of these, the second and fourth were by far the most important, and a brief notice of their course and conclusion is subjoined.

SUCCESSION, WAR OF THE SPANISH, arose on the death, without issue or collateral male heirs, of Charles II., king of Spain, Nov. 3, 1700. The nearest natural heir to the throne was of the royal line of France, Charles's elder sister having married Louis XIV.; but to prevent any possible union of the two crowns, a solemn renunciation had been exacted both from Louis and his queen, for themselves *and their heirs*; and this renunciation having been ratified by the king and cortes of Spain, was made as binding as legal forms could make it. Failing the Bourbons, the next heirs were the descendants of the younger sister of Charles, who had married the emperor Leopold I., and from whom no renunciation had been exacted; and the only issue being a daughter, who had married the elector of Bavaria, and borne a son, Joseph Ferdinand, this prince was during his lifetime regarded both by Charles II. and the Spanish people as the rightful heir. But, dying in 1699 without issue, the question of succession was reopened, Louis XIV., failing his wife's rights, claiming for himself, as the son of Philip IV.'s elder sister (being, however, again legally barred here by another solemn renunciation); while the emperor Leopold, maintaining with justice that the Bourbons were by these two renunciations wholly deprived of all their rights of heirship, claimed the throne as the son of Philip IV.'s younger sister. The other powers of Europe, especially Britain, Holland, and Germany, warmly interested themselves in the matter, as a question of policy, and with good reason; for not only was the crown of Spain a valuable prize in itself, carrying with it the sovereignty of the Netherlands, the Milanese, Naples, and Sicily, and immense possessions in America, but its union with France or Austria would of a certainty endanger the independence of every other sovereignty in Europe. Both claimants bade for the support of the maritime powers, the one by renouncing his claims in favor of his second grandson, Philip of Anjou, the other by putting forward his second son, Charles, as his substitute, while both solemnly promised never to undertake the union of the two crowns. The Austrian party at first preponderated in Spain; but Louis, by able and unscrupulous policy, succeeded in undermining the Austrian influence at Madrid, and in having Philip declared the heir (Oct. 2, 1700). On the death of king Charles, a month

after, Philip appeared in Spain, and was well received by all classes, and at once recognized as monarch, an example gradually and unwillingly followed by all the European powers excepting the emperor; for at that time the dread of Louis XIV.'s power pressed like an incubus on the nations of Europe. However, the French monarch, by various ill-advised acts, chiefly by his support of the elder pretender (the son of James II.), whom he recognized as sovereign of Britain, and by occupation of the Netherlands and menacing treatment of Holland, stirred up such general resentment, that William III. was enabled to revive the *grand alliance*, and his successor, Anne, to join with Holland and Austria in declaring war against France and the "Spanish usurper," May 15, 1702.

Hostilities at once commenced; a combined British-Dutch-German army under Marlborough attacked the French in Belgium, and captured one by one their fortresses on the Maes, while the Reichs army (Germany having declared for Austria), under the Markgraf of Baden, crossed the Rhine, and took Landau. Austria herself had, however, commenced the contest in the previous year by sending into Italy prince Eugene (q.v.) of Savoy-Carignan at the head of a veteran army of 32,000 men, who did a good deal of hard fighting, with no adequate result. Meanwhile, the elector of Bavaria raised an army and declared for France, and a French army under Villars marched to join him. Both were kept in check by the Markgraf for some time; but, in the summer of 1703, Villars burst through the Black Forest, and joined the elector, with the view of penetrating through Bavaria into Austria, but his obstinate ally, the elector, was determined to invade the Tyrol instead, and join Vendome in northern Italy—a scheme which ended most disastrously; and Villars returned in disgust to France. In the Low Countries, Marlborough employed himself in gradually depriving the French of their strongholds: in Italy the Austrians were driven from point to point, till nothing remained to them but a few districts on the Po; they were, however, relieved toward the close of the year by the defection from France of the duke of Savoy, who joined the grand alliance Oct. 25, 1703, an event which compelled Vendome to return to Piedmont. The first great blow was struck in the following year, when the combined Austrian-German-British army, under Marlborough, totally defeated the French and the elector at Blenheim (q.v.), driving the débris of their forces almost to the foot of the Vosges. After this the French never obtained a permanent footing in Germany. The campaigns of Marlborough in Germany, and of Eugene in Italy, in 1705, were successful but not very important. The year 1706 was another great epoch in this protracted contest; the British and Dutch having freed the valley of the Maes, had forced the French into South Brabant, and Marlborough having, by a stratagem, caused them to march toward Namur, suddenly attacked them at Ramillies (q.v.) and, after a brief combat, put them completely to rout with great slaughter, the elector and Villeroy, the joint commanders, narrowly escaping capture. Louis hastily re-enforced his army, and recalled Vendome from Italy to take the command, a step which, however necessary, cleared the way for Eugene who completely out-generaled his opponent Marsin, and after a memorable march of 34 days, appeared before Turin, and united with the duke of Savoy. The battle of Turin, in which the gallant Marsin was slain, was one of the most obstinate of the whole war, but its result was as decisive, and from this period the French power in northern Italy was shattered: and the following year saw the country completely cleared of both French and Spaniards. From 1706 the war in Germany was purely defensive, and no battle worthy of notice was fought. In Italy also the contest on the whole languished, though the Austrian arms were for the most part successful, Mantua and Naples (1708) being subdued, and the pope compelled to preserve neutrality by dread of another sack of Rome. But since the commencement of 1704, another theater of war had been established by the landing of the archduke Charles at Lisbon with 8,000 British and 6,000 Dutch troops, who were joined by the Portuguese (their king having acceded to the alliance against France), and invaded Spain from the west; but nothing of consequence was accomplished till a landing had been effected by the earl of Peterborough (q.v.), with a small body of troops, in Catalonia. Then attacked both from the w. and e., the Bourbon forces were beaten and driven across the Pyrenees, and it was only after the departure of Peterborough that Berwick (q.v.) made head against his antagonists. By his victory at Almanza (April 25, 1707), he recovered the whole of Spain except Catalonia. In 1710 Berwick finally left Spain; and the Carlists under Stanhope and Starhemberg again got the upper hand, repossessing themselves of the e. of Spain, and of Madrid (Sept. 28). But the arrival of Vendome speedily changed the face of affairs. Stanhope was defeated and captured (Dec. 9) at Brihuega, and Starhemberg was forced to retreat on the following day. The war was thenceforth confined to Catalonia, and was distinguished by no noteworthy incidents. The most important part of the struggle had been meanwhile taking place in the Netherlands, where Marlborough (1707) drew up in concert with Eugene a secret plan of operations which affected a division of the Moselle army under the elector and Berwick from that of the north under Vendome; whereupon the British and Germans swiftly uniting fell upon Vendome's army at Oudenarde (q.v.) (1708), and before Berwick could come up to its aid, inflicted upon it a severe defeat. The capture of Lille, Ghent, and Bruges necessarily followed. France now began to show symptoms of exhaustion, and made overtures of peace, but these being elixily illusory, were rejected; and the emperor having largely re-enforced Eugene, the allies took the field with 110,000 men,

while the French, equal in strength, were now directed by Villars, the most enterprising and fortunate of their generals; but his star, which had hitherto been constantly in the ascendant, fell before that of Marlborough at Malplaquet (q. v.) (Sept., 1709). After some further campaigning, besieging, and negotiating, the opportune death of the emperor (April 17, 1711) rescued France from the brink of destruction; for Britain became immediately lukewarm in support of a cause which would effect the reunion of Austria and Spain; and the tories having come into power, private preliminaries of peace were signed between Britain and France, Oct. 8, 1711. Eugene, however, continued the war, aided by Holland, and captured Quesnoy; but the defeat and capture of the earl of Albermarle and the British contingent at Denain (July, 1712) so weakened his force, that he was compelled to give way; and in the following spring the Dutch joined the British as parties to the peace of Utrecht (q. v.). The emperor Charles was also forced to conclude a treaty of peace at Baden, Sept. 7, 1714, which ended the struggle, leaving Philip in possession of the Spanish throne (see *UTRECHT, PEACE OF*); while Austria obtained the Spanish Netherlands and the Milanese.

SUCCESSION, WAR OF THE AUSTRIAN. The death of the emperor Charles VI. (Oct. 20, 1740), by which the male line of the house of Hapsburg became extinct, was the signal for a general uprising of the powers of Europe, some to prey on the Austrian possessions, and others to aid the eldest daughter and heir of the deceased emperor. The probability of such a contingency had long been foreseen by Charles VI., for as early as 1713 he had published a *Pragmatic Sanction* (q. v.), stipulating that, in default of male heirs, the whole of his dominions should descend undivided to his eldest daughter, Maria Theresa (q. v.); and it was almost his sole aim, during his subsequent reign, to gain the consent of all parties having proximate claims to any of the Austrian domains, and of the principal powers of Europe, to this arrangement. The elector of Bavaria, Charles Albert, alone refused to resign his pretensions. On the death of her father, Maria Theresa intimated her accession to the various European powers, and from all of them, except France and Bavaria, received assurances of good-will and support; but notwithstanding, two months did not elapse till Frederick II. of Prussia, without a declaration of war, invaded Silesia. The Austrian treasury was at this time exhausted, and the army much disorganized; so that little or no effective resistance could be made to the Prussians; while the state of alarm into which this sudden attack had thrown the court of Vienna was increased by doubts as to the intentions of France. These doubts were soon resolved by the latter, in the spring of 1741, forming a confederacy of all the claimants to the Austrian dominions—the electors of Bavaria and Saxony, sons-in-law of the emperor Joseph I.; Philip V. of Spain; Charles Emmanuel of Sardinia, who claimed the Milanese; and Frederick II. of Prussia, who *now* demanded almost the whole of Silesia. On the other hand, Britain granted Maria Theresa an annual subsidy of £300,000; the Dutch were willing to aid her when opportunity offered; and Hungary gallantly responded to her pathetic appeal by sending in thousands her motley population, Magyars, Croats, Slavs, and Tzpatches, to fight in defense of their heroic queen. Meantime the Bavarians, in conjunction with the French under Belleisle, overran the greater part of Bohemia. This invasion compelled the queen to buy off her most formidable opponent, Prussia, by the surrender of Silesia and Glatz; and then, while prince Charles of Lorraine kept the French at bay in Bohemia, Khevenhuller, the most enterprising of the Austrian generals, advanced up the valley of the Danube, captured 12,000 French in Linz, overran Bavaria, and on the very day of the elector's coronation as the emperor Charles VII., took Munich his capital (Feb. 12, 1742). But this great success alarmed Frederick II. for the security of his new possessions, and abruptly breaking the treaty, he poured his forces into Bohemia and upper Austria, and gained the battle of Chotusitz (May 17). The same year witnessed increased activity on the part of Britain (the Walpole administration being now in power) and Holland on behalf of Austria; the expulsion of the French and Bavarians from Bohemia; the severance of the king of Sardinia from the coalition against Austria, produced by the bribe of some districts of the Milanese, which, however, he did not obtain till some time afterward; the enforcement of neutrality upon Naples by the threatening attitude of a British fleet off the capital; and, on the other hand, the recovery of Bavaria by the elector.

In May, 1743, Bavaria again fell into the hands of prince Charles and Khevenhuller; count Saxe was driven with great loss from the Palatinate; the "emperor" Charles Albert and the Swedes, disgusted at their ill-success in the war, retired from the contest, so that France and Spain now remained the sole representatives of the once mighty coalition. In 1744, France and Britain, which had hitherto engaged in the conflict only as allies, declared war on each other; and the latter proceeded to destroy piecemeal the French and Spanish shipping on the high seas, and to attack their colonial possessions. For this, however, the successes of Saxe in the Netherlands were a compensation. However, the great successes of Austria on the Rhine, and the ill-concealed ambitious projects of Maria Theresa, again alarmed Frederick II. for Silesia; and he resolved on another attempt to rivet his hold on the much-coveted province before it was too late. Accordingly, he concluded at Frankfurt (May 13, 1744), a secret convention with France, the emperor, the elector-palatine, and the king of Sweden. Bursting into Bohemia with his usual celerity, Frederick II. forced the Austrians at once to return from Alsace, thus enabling the elector to recapture Bavaria; but before prince Charles had time to reach

Bohemia, a fresh levy of 44,000 men, which had been raised by the chivalrous and patriotic Hungarians, joined by 6,000 Saxons, had reached the Prussians, and by cutting off their supplies, and capturing their stragglers and foraging parties, compelled them to evacuate the kingdom with considerable loss. In Italy, the Spaniards, who were now joined by the Neapolitans, were defeated repeatedly, and compelled to retreat down the peninsula; and the king of Sardinia succeeded in preventing the French from effecting a permanent lodgment in n.w. Italy. In January, 1745, the emperor-elect died, and his son, Maximilian Joseph, profiting from his father's misfortunes, declined to take part in the contest, or to allow himself to be nominated emperor, and made peace with Austria. Frederick II., displeased with the meddling and overbearing conduct of France with respect to the approaching imperial election, also sought to come to terms with Austria, by the mediation of Britain, and the peace of Dresden (Dec. 25, 1745) finally withdrew Prussia from the conflict. In Flanders, the fortunes of Austria also declined; and after the victory of Fontenoy (May 11, 1745) she could not prevent Saxe from capturing the chief Belgian fortresses in succession. In Italy, also, fortune declared for the coalition; for the Spanish-Neapolitan army, now re-enforced by the Genoese and Modenese—70,000 men in all—defied all opposition, overran the whole of Lombardy and much of the Sardinian territories, driving the king under the walls of his capital. Similar reverses befell the allies in Flanders during the campaign of 1746; but these were more than counterbalanced by the great successes obtained in Italy, where all the lost fortresses of Lombardy, Parma, and Guastalla, were recaptured, the coalition army totally routed in a great battle near Placentia (June 16), and Genoa overrun and occupied. Another of fortune's favors to Austria was the death of Philip V. of Spain (July 9), which, by depriving that arch-plotter, his queen, of the supreme power, considerably diminished the zeal of the Spanish court in the prosecution of the war. In 1747, the Dutch, who had hitherto escaped the ravages of war, were made practically acquainted with them by Saxe, who, having completely subdued the Austrian Netherlands, invaded and overran Dutch Flanders, routed the unfortunate duke of Cumberland at Lafeldt (July 2), while his celebrated chief of engineers, count Lowendal, after a two months' siege, took Bergen-op-Zoom, Cohorn's masterpiece, a fortress believed by the Dutch to be impregnable. At the commencement of 1748, Britain, France, and Holland sought to bring about a peace, and agreed among themselves to certain preliminaries, which were submitted to Austria and Sardinia; but as one of them was the surrender of Parma and Placentia to don Philip of Spain, the former refused her consent; and her two allies, disgusted at her disregard of the sacrifices they had made on her behalf, at once signed the preliminaries (April 30), and Austria sullenly followed suit on May 18. Much discussion followed, but on Oct. 18, 1748, the treaty of Aix-la-Chapelle (q.v.) put an end to this most disastrous war, which left the Hapsburgs in possession of their hereditary dominions, with the exception of Silesia and some of their Italian provinces. See AIX-LA-CHAPELLE.

SUCCINIC ACID ($C_4H_4O_4 \cdot 2H_2O$) derives its name from its having been originally found in amber (Lat. *succinum*), and is one of the group of dibasic acids of the oxalic acid series, whose general formula is $C_nH_{2n-4}O_4 \cdot 2H_2O$. Succinic acid occurs as a natural constituent not only in amber, but also in the resins of many of the pine tribe, in the leaves of the lettuce and wormwood; and, in the animal kingdom, it has been detected in the fluids of hydatid cysts and hydrocele, in the parenchymatous juices of the thymus gland of the calf, and of the pancreas and thyroid gland of the ox.

One of the most important points in connection with succinic acid is its convertibility into tartaric acid, while tartaric acid may in its turn be reconverted into succinic acid.

SUCCORY. See CHICORY, *ante*.

SUCCULENT PLANTS are those plants remarkable for the thick and fleshy or succulent character of their stems and leaves. This character prevails in the natural orders *cactaceæ*, *mesembryaceæ*, and *crassulacæ*, but frequently appears also in genera of other natural orders, as in aloe and some other *liliacæ*. It consists in a peculiar development of cellular tissue. Succulent plants are remarkable for the small number of stomata (q.v.) on the green surface. They are generally found in dry climates, often as almost the only vegetation of the most arid places; although some of them occur in situations where moisture is often abundant; their peculiar structure, however, being apparently intended to adapt them for enduring occasional droughts. Thus, there are not only succulent plants in the Sahara and other deserts, but in Britain, and some of them form a conspicuous feature of the flora of the mountains of Europe—as species of *sedum*, *rhodiola rosea*, etc.—where they are found in situations sometimes abounding in moisture, but occasionally parched—on bare rocks, steep slopes with scanty soil, and the like. By the want of stomata and the store of moisture in their own cellular tissue, they are adapted for the endurance of long droughts. Yet they live in great part by nourishment derived from the atmosphere, rather than from the soil; a fact which may easily be proved by suspending a specimen of the common yellow stonecrop (*sedum acre*) by means of a string, when it will be found to flourish for a considerable time, and sometimes to preserve its vitality as long as those planted in the ground. In dry tropical countries, succulent plants perform in part the same office which lichens and mosses do in colder regions, in preparing the first mold for future vegetation.

SUCHET, LOUIS-GABRIEL, Duke of Albufera, and marshal of France, was descended from an honorable family, and b. at Lyons, Mar. 2, 1770. He volunteered as a private into the cavalry of the Lyons national guard in 1792, and subsequently became attached to the army of Italy. His rare intelligence and brilliant valor, displayed at Lodi, Rivoli, Castiglione, Arcola, and in numerous battles of less note, laid the foundation of his military reputation, and in 1798 he became gen. of brigade. The able manner in which he, with a force not one-sixth of that of the Austrians, kept Melas in check (1800), preventing the invasion of the s. of France, and ultimately capturing 15,000 prisoners, is one of the most brilliant military feats on record. Suchet also took a distinguished part in the campaigns against Austria (1805) and Prussia (1806), and was subsequently (April, 1809) appointed generalissimo of the French army in Aragon, where, for the first time, he appears as holding an independent command. The part of Spain committed to his charge, though inhabited by a people distinguished by their obstinacy and patriotism above all others in Spain, was completely subdued, more, however, through his just and able administration, and the strict discipline which he maintained, than by military talent. The latter quality he was only called upon to exercise against Spanish troops, which he had little difficulty in annihilating. In the first few days of 1812 he conquered Valencia, and obtained in addition to his dignity of marshal (July 8, 1811) that of duke of Albufera, and the grant of a magnificent domain. The five campaigns which he made in the peninsula are considered perfect models of the kind of service he had to perform—viz., to rivet the chains of a foreign domination on the necks of a patriotic and high-spirited people. The details have been well given by him in his *Mémoires sur ses Campagnes en Espagne* (Paris, 1829–34, 2 vols. with atlas). But the misfortunes of the other French armies in Spain compelled Suchet gradually to relinquish all his conquests. He was created a peer by Louis XVIII., but took service under his old master after his return from Elba, and was charged with the defense of the s.w. frontier. Deprived of his peerage at the second restoration, he did not return to court till 1819, when it was restored, and he soon rose high in royal favor. He died at the château of Saint Joseph, near Marseilles, Jan. 3, 1826. Napoleon's high opinion of Suchet's military talents is recorded by O'Meara and Las Casas, and, according to his classification, Suchet ranked second, Massena being first.—His son and successor in the dukedom of Albufera was a member of the corps législatif, and a supporter of the Napoleonic policy under the emperor Napoleon III.

SUCKING-FISH, a name sometimes given to the remora (q.v.), and to fishes of the family discoboli (q.v.), which have a sucker formed by the union of the ventral fins, and are capable of attaching themselves by it to stones or other substances. The best known of the British species, and the only one which is of any value as an article of food, is the lump-sucker (q.v.). Several other species occur on the British coasts, to which the name **SUCKER** is generally given, as the **CORNISH SUCKER** (*lepidogaster Cornubiensis*), and the **UNCUTS SUCKER** or sea-snail (*iparis vulgaris*). They are small fishes, destitute of scales.

SUCKLING, Sir JOHN, one of the brilliant cavalier poets of the court of Charles I., was born at Whitton, in Middlesex, and baptized Feb. 10, 1608–9. His father, also a knight, held office as a secretary of state, and comptroller of the household, but died in 1627, when the poet was in his eighteenth year. The latter inherited large estates; and having completed his education at Trinity college, Cambridge, he went abroad, and served for some time in Germany under Gustavus Adolphus. He returned about 1632, and was soon distinguished for his wit, gallantry, and lavish expenditure. To aid the king against the Scots he raised a troop of 100 horsemen, whom he clad in a rich and gaudy uniform of white and red, with plumes of red feathers in their caps. This loyal corps is said to have cost the poet about £12,000. They rode n.; but no sooner had the cavalry come within sight of the Scots' army at Dunse than they turned and fled without aiming a blow! This disgrace gave occasion to numerous lampoons, and to a clever though coarse ballad against Suckling's gay horsemen; but in reality they behaved no worse than the rest of the English army. Their loyal commander next joined in a scheme to rescue Strafford from the Tower, and this being discovered, he fled for safety to the continent. He died, while yet in the flower of his life and genius, in 1641 or 1642. Various accounts are given of the circumstances attending his death, but the most painful of these, viz., that he poisoned himself in Paris, is confirmed by family tradition. See the memoir by the rev. Alfred Suckling (1836), prefixed to a volume of *Selections from the Works of Sir John Suckling*. He had probably run through his fortune, and dreaded want, as well as despaired of the success of the royal arms. The works of Suckling consist of four plays, now utterly forgotten, a prose treatise entitled *An Account of Religion by Reason*; a collection of *Letters*, written in a stiff, artificial style; and a series of miscellaneous poems, beginning with *A Session of the Poets*, published in 1637, which is original in style, and happily descriptive of the author's contemporaries. But the fame of Suckling rests on his songs and ballads, which are inimitable for their ease, gaiety, and pure poetic diction. His ballad of *The Wedding* is still unsurpassed, and one simile in his description of the bride—

Her feet beneath her petticoat,
Like little mice, stole in and out,
As if they feared the light—

has had the honor of being copied by Herrick and Congreve.

SUCRE. See CHUQUISACA.

SUCRÉ, ANTONIO JOSÉ DE, 1793-1830; b. Venezuela; educated at Caraccas. When 18 years old he entered the patriot army, and in 1822 held a command at Pichincha. In 1823 he became the chief of the Peruvian patriots, and the next year won the battle of Ayacucho, which brought about the independence of Peru. By the legislature of Bolivia he was chosen president for life in return for his efforts in rendering that republic free. In 1827 an insurrection took place in which Sucre was wounded. He then resigned, engaged in the war between Colombia and Peru, and defeated the Peruvian army under Lamar at Tarqui, 1829. He was chosen president of the first congress of the republics which met in Bogota, 1830, and on his return was assassinated, it was said, by order of Obando.

SUCTORIA, an order of insects, containing only those forming the Linnean genus *pulex*. See FLEA.

SUDAMINA, or MILIARY ERUPTION, is one of the diseases of the skin belonging to the class *vesiculæ*, or *vesicæ*. The former name is derived from the fact that the disorder is always accompanied with profuse sweating; while the latter has reference to the size of vesicles, which do not exceed those of a millet-seed. The vesicles are most abundant on the neck and trunk, and are sometimes, but not always, attended with itching. They almost always occur in association with febrile disorders, which, however, do not seem in any way modified by these occurrences. The only known condition that favors their production is copious and prolonged sweating. They sometimes appear in health during the summer heat, when strong exercise has induced copious sweating. Pathologically this disease is of so little importance that it is unnecessary to notice its treatment. It is, however, sometimes useful as a sign in diagnosis, especially in typhus and typhoid fevers.

SUDAN. See SOODAN, *ante*.

SUDBURY, a municipal borough of Suffolk, 16 m. s. of Bury St. Edmunds, on the left bank of the Stour, across which a bridge connects the town with the suburb of Balingdon in Essex. The silk and bunting manufactures are the most important branches of industry. There are also brick-works, in which the white clay used is notable for its purity. Malting is carried on. Sudbury was one of the first towns into which the woolen manufacture was introduced by the Flemings. Pop. '71, 6,908.

SUDDEN DEATH may be induced by natural or by violent causes, and the detection of the true cause is obviously of very great importance, since the acquittal or conviction of a suspected person may depend upon it. Sudden death may occur naturally from syncope (fainting or swooning), from asphyxia (literally pulselessness), or, more correctly, apnea (privation of breath), or from coma (insensibility). Syncope, or sudden cessation of the heart's action, may occur, as Dr. C. J. B. Williams points out in his *Principles of Medicine*, in two ways: "(1.) By the heart losing its irritability (or becoming paralyzed), so that it ceases to contract; and (2.) by its being affected with tonic spasm, in which it remains rigidly contracted, losing its usual alternation of relaxation. Sudden death from asphyxia, or, more correctly, from apnea, occurs when, from any cause, the entrance of air into the lungs is prevented. It is not so often witnessed as a result of disease as of accident. It is sometimes caused by a spasmodic closure of the rink of the glottis (see LARYNX). Sudden death from coma is liable to occur in apoplexy and injuries of the head.

In all cases of sudden death there is a strong tendency on the part of the public to suspect the poisoning. It is very hard to make them understand that persons may die a natural death suddenly as well as slowly; or conversely, that death may really take place slowly, and yet be the result of poison. "One of the means," says Dr. Taylor, "recommended for distinguishing narcotic poisoning from apoplexy or disease of the heart is the difference in the rapidity with which death takes place. Thus apoplexy, or disease of the heart may prove fatal either instantly or within an hour. The only poisons likely to operate with such fatal rapidity are prussic acid or nicotina. Poisoning by opium is commonly protracted for five or six hours. This poison has never been known to destroy life instantaneously or within a few minutes. Thus, then, it may happen that death will occur with such rapidity as to render it impossible, under the circumstances, to attribute it to narcotic poison."—*Op. cit.*, p. 145.

In its relations to medicine and medical jurisprudence the subject of this article has been fully discussed by Herrick and Popp, *Der plötzliche Tod aus inneren Ursachen*, 1848.

SUDETENGEIRGE, the most important mountain-range of Germany, dividing Prussian Silesia and Lausitz from Bohemia and Moravia, and connecting the Carpathians with the mountains of Franconia. It does not form a continuous chain except in the middle, where it is known under the names of Riesengebirge (q.v.) and Isergebirge; the ends, both toward the n.w. and s.e., broadening out into great rugged hilly plateaus, with broken chains and isolated peaks. The Sudetengebirge are composed chiefly of granite, gneiss, mica-schist, and porphyry, with superimposed beds of basalt and coal, and are clothed with pines to a height of between 2,000 and 3,000 feet. They are rich in minerals, especially in the metals, iron, lead, copper, zinc, tin, cobalt, with some silver and gold. Schneekoppe (Snow-peak) in the Riesengebirge, about 5,000 ft. high, is the cul-

minating point in the whole range.—The name Sudetengebirge is applied in a narrower sense to the s.e. portion of the range separating Silesia from Moravia.

SU DRA is the name of the fourth caste of the Hindus. See **CASTE**.

SUE, MARIE-JOSEPH-EUGÈNE, a well-known French novelist, was born at Paris Dec. 10, 1804. His father, Jean-Joseph Sue, was one of the household physicians of Napoleon, and he educated his son for his own profession. At the age of twenty the young man became an army-surgeon. In this capacity he served in the French expedition to Spain, under the duke of Angoulême, in 1823. Subsequently he transferred himself to the navy; and in 1828 was present at the battle of Navarino. In 1829 his father died, leaving him a handsome fortune, on the acquisition of which he ceased to practice his profession. After coquetting a little with art he betook himself seriously to literature, and very soon, in the department of fiction, he achieved a considerable popularity. His earlier efforts were sea-stories, somewhat after the manner of Cooper, or romances in imitation of Scott; and though in both fields he displayed talent, his true power was scarcely as yet developed. Something of it may, however, be traced in his *Mathilde, ou les Mémoires d'une Jeune Femme*, published in 1841; but it was first decisively made manifest in the famous *Mystères de Paris*, which began to appear the year after in the columns of the *Journal des Débats*. The furor of excitement occasioned by this work and its successor—*Le Juif Errant*—which appeared in the *Constitutionnel*, not only in France but elsewhere, has seldom, perhaps, been exceeded; and for both the writer received large sums of money. In 1846 his *Martin, l'Enfant Trouvé* was issued; in 1847–8 appeared *Les Sept Péchés Capiteux*; and in 1852 he published *Les Mystères du Peuple*, his last work of any importance. Throughout Sue's latest works there runs a vein of socialism; and at the revolution of 1848 he allied himself with the extremist sect of the republicans. On April 28, 1850, he was elected deputy to the legislative assembly for the department of the Seine, and was assiduous in his duties as such till the *coup d'état* of Dec., 1852, by which he was driven into exile. He retired to Savoy; and at Annecy he died July 3, 1857.

In the writings of Sue great power is displayed; but it is rather of the unhealthy kind, and depends for much of its effect on vicious sources of interest. His books are read once with a fever-heat of curiosity, and scarcely bear reperusal.

SUE CA. a t. of Spain, in Valencia, and 23 m. s. of the city of that name, on the Jucar, about 4 m. from the Mediterranean. Brick and tile works are in operation, and there are several flour and rice mills. Pop. 9,100.

SU ET is a variety of solid fatty tissue, which accumulates in considerable quantity about the kidneys and the omentum of several domestic animals, especially the ox and sheep. Beef suet is extensively used in cookery, while purified mutton-suet under the name of *Serum Præparatum* occurs in the Pharmacopœia, and is obtained by melting and straining the internal abdominal fat. It consists of a mixture of ordinary animal fats with a great preponderance of the most solid of them, viz., stearin, which constitutes about three-fourths of the whole. The pure suet of the Pharmacopœia is "white, soft, smooth, almost scentless; and is fusible at 103°." It is used as an ingredient in cerates, plasters, and ointments. Ordinary melted suet is frequently employed in the same manner as lard, to preserve potted meats or fish and similar articles from the action of the air.

SUETONIUS, CAIUS TRANQUILLUS, son of Suetonius Lenis, a tribune of the 13th legion under Otho, was born probably a few years after the death of Nero. He is known to us chiefly as a Roman historian and miscellaneous writer, for his merits as which he is highly praised by the younger Pliny. He was also, it is supposed, a teacher of grammar and rhetoric, and a composer of exercises in pleading; nay, from a letter of Pliny's to him, it may be gathered that he sometimes pleaded causes in person. Pliny procured him the dignity of military tribune, which, by Suetonius's desire, he got transferred to another. Though childless, Suetonius was, through the same friendly agency, presented by Trajan with the *jus trium liberorum*, which, in that reign, was only to be had by great interest. He was afterward secretary of the emperor Adrian, whose favor he had secured. The date of his death is unknown. All his works (among which, as we learn from Suidas, there were several on topics usually treated by grammarians) have been lost, except his *Lives of the Cæsars*, his *Lives of Eminent Grammarians*, and (in part only) his *Lives of Eminent Rhetoricians*. It is by the first of these works that he is most favorably known, replete as it is with information about the twelve Cæsars, from C. Julius to Domitian, which is to be had nowhere else, and abounding with anecdotes which, while they too often prove the profligacy of his heroes, testify to the impartiality of their chronicler. From a period long before the renaissance to the present, these "Lives" have always been favorite reading, and have found numerous editors, the best of whom is still Burmann (Amsterdam, 1736), and numerous translators into nearly every European language.

SUE VI. first mentioned by Cæsar, in whose history (*De bello Gallico*) the name is employed as the collective designation of a great number of Germanic peoples. They occupied a district of indefinite extent on the eastern side of the Rhine, and may have been the same tribes as those subsequently known as Chatti, Longobardi, etc. Cæsar

states that their territory comprised 100 cantons, and was densely wooded, that they had towns (*oppida*), but no strongholds, and that every year a part of the population left their homes to seek employment in war. The Suevi of whom Tacitus speaks (*Germania*, 38, etc.) seem to have dwelt n. and e. of the Suevi of Caesar, extending as far as the Elbe and the Baltic, which Tacitus calls the "Suevic sea." The peoples united under the rule of Maroboduus, the Marcomannic chief, were Suevic, and hence the Marcomanni and Quadi, who figure in the reigns of Marcus Aurelius and Aurélian, are often called Suevi. After the name had fallen into disuse as a collective designation, it re-appeared (second half of the 3d c., *Ann. Marc.*, etc.) as the name of a people occupying the same territory as the Suevi of Caesar, who appear, however, to have been a mixed race made up of adventurers from different parts of Germany, and who probably took the name of Suevi after possessing themselves of the country. We find them in alliance with the Burgundians, Alemanni, Alani, Vandals, etc. They are among the most notable of the barbaric peoples that broke up the Roman empire in the n.w. and west. Bursting through the passes of the Pyrenees (409 A.D.), they along with the Vandals, overran and wasted Spain (q.v.). Those who remained at home in Germany seem to have spread during the 5th c. e. to the Neckar and the Raurhe Alps, and s. as far as Switzerland. The mediæval Swabians were their direct descendants.

SUEZ, until recently, a small, ill-built, wretched-looking town, on an angle of land near the northern extremity of the gulf of Suez, 76 m. e. of Cairo, with which it is connected by railway. The pop. was officially returned, in 1872, as 13,498. It is walled on all sides but that toward the sea, has an indifferent harbor, but a tolerably good quay. Suez of late has been greatly improved. English and French houses, offices, and warehouses have been erected in every direction, and the bazaars are assuming a respectable appearance. These bazaars are provided with clarified butter from Sinai, with fowls, grain, and vegetables from the Egyptian province of Sharkijeh, and with wool, dates, and cotton. Rain falls but seldom, sometimes not once in three years. All around stretches a burning waste of sands. Suez owes its modern prosperity to the establishment of what is known as the *overland route* (q.v.) to India, in consequence of which a large portion of the traffic between England (and other European countries) and the east passes through the place; and to the opening of the Suez canal in 1869. For a long time previous to the establishment of the overland route, Suez had been in a state of complete decay, although, at a yet earlier period—previous, in fact, to the discovery of the sea-route to India by the cape of Good Hope—it was a flourishing emporium of the products of east and west. A salt manufactory was recently established here by the Egyptian government, and from May to July, 1875, six thousand tons of salt were sent to India.

The **GULF OF SUEZ** is the western and larger of the two branches into which the Red sea divides toward its northern extremity, and washes on the w. the coasts of Egypt, on the e. those of the Sinaitic peninsula. Extreme length, 200 m.; average breadth, about 20 miles. The shores are sometimes low, barren, and sandy wastes, sometimes bold and rocky headlands.

The **ISTHMUS OF SUEZ** is a neck of land 72 m. in width at its narrowest part, extending from the gulf of Suez on the s. to the Mediterranean on the n., and connecting the continents of Asia and Africa. It embraces within its limits (according to the commonly received opinion) the fertile Goshen (q.v.) of antiquity; but it is now a wretched uninhabitable waste, consisting of mingled sand and sandstone, interrupted here and there with salt swamps or lakes, but almost entirely destitute of fresh water. The main interest that attached to this region, in recent times, was, whether or not—since Egypt was on the great highway to India and China—it was practicable to cut a ship-canal through the isthmus. We shall here briefly indicate the main steps that were taken to have this important question solved in a satisfactory manner.

It is certain that, in ancient times, a canal connecting (indirectly) the two seas did exist. At what period it was constructed is not so certain. Herodotus ascribes its projection and partial execution to Pharaoh Necho (about 600 years B.C.); Aristotle, Strabo, and Pliny less felicitously fix on the half-mythical Sesostris as its originator. The honor of its completion is assigned by some to Darius, king of Persia, by others to the Ptolemies. It began at about a mile and a half from Suez, and was carried in a north-westerly direction, through a remarkable series of natural depressions, to Bubastis, on the Pelusiac or eastern branch of the Nile. Its entire length was 92 m. (of which upward of 60 were cut by human labor) its width from 108 to 165 ft., and its depth 15 (Pliny says 30) feet. How long it continued to be used, we cannot tell; but at length it became choked up with sand, was restored by Trajan early in the 2d c. A.D., but again became unusable from the same cause, and so remained till the conquest of Egypt by Amron, the Arab general of the calif Omar, who caused it to be reopened, and named it the "Canal of the Prince of the Faithful," under which designation it continued to be employed for upward of a century, but was finally blocked up by the unconquerable sands, 767 A.D. In this condition it has ever since remained. The attention of Europe was first turned to it in modern times during the invasion of Egypt by Bonaparte, who caused the isthmus to be surveyed by a body of engineers, who arrived at the opinion that the level of the Mediterranean is 30 ft. below that of the Red sea at Suez, an opinion

which a subsequent survey proved to be erroneous. From this time, the question continued to be agitated at intervals, especially by the French, and various plans were proposed, but nothing definite was arrived at till 1847, when France, England, and Austria sent out a commission to measure accurately the levels of the two seas. The commissioners, M. Talabot, Mr. Robert Stephenson, and signor Nigrelli, ascertained that, instead of a difference of 30 ft., the two seas have *exactly the same mean level*. The only noticeable difference was, that there is a tide of $6\frac{1}{2}$ ft. at the one end and $1\frac{1}{2}$ ft. at the other. Another examination leading to similar results was made in 1853. Mr. Stephenson expressed himself very strongly against the feasibility of a canal, that is to say, a canal of such dimensions as would suit the requirements of modern commerce, and planned, instead, a railway from Cairo to Suez, which was opened (1858), and which now conveys overland all our Indian and Australian mails. The French, however, were not satisfied with Mr. Stephenson's conclusions, and M. Talabot, on his return to Europe, published in the *Revue des Deux Mondes* a plan for connecting the two seas by way of Alexandria and Suez (or rather a point 6 m. below Suez), for a description of which we have not space. In 1854 a new experimenter appeared in the person of M. de Lesseps, a member of the French diplomatic service in Egypt, who (1856) obtained from the pasha the "concession," i.e., the exclusive privilege of forming a ship-canal from Tyneh (near the ruins of ancient Pelusium) to Suez. The peculiarity of M. de Lesseps's plan lay in this, that, instead of following an oblique course, and uniting his canal with the Nile, as the ancients had done, and as all the modern engineers had thought of doing, he proposed to cut a canal right through the isthmus in a straight line to Suez. This canal was to have a minimum width at the surface of 262 ft., and at the bottom of 144 ft., with a depth of $22\frac{1}{2}$ ft.; and at each end there was to be a sluice-lock formed, 330 ft. long by 70 wide. By taking advantage of the tides at Suez, it was hoped that an additional depth of 3 or 4 ft. might be obtained. But the colossal feature of M. de Lesseps's plan was the artificial harbors which he proposed to execute at the two ends, Tyneh and Suez. That at the Mediterranean end was to be carried out 5 m. in order to obtain a permanent depth of water for a ship drawing 23 ft., on account of the enormous quantity of mud-sand which the Nile annually pours out (30,000,000 cubic yards, it is said), and which the prevalent wind drives eastward along the shore toward the southern coast of Palestine. The quantity of stone required to construct this harbor has been calculated variously at from 3 to 12 million cubic yards, and there are no stone quarries except at a great distance from Tyneh! The pier at Suez was to be carried out 3 m., and in other respects the difficulties, though great, were not, as on the Mediterranean coast, *almost* insurmountable. The English for political, perhaps, as well as for practical reasons, looked with aversion on M. de Lesseps's scheme; but in 1855, the question was again taken up in an international spirit, a new European commission was appointed, which reported that M. de Lesseps's scheme, somewhat modified, *was practicable*, and that a canal might profitably be constructed. The result of the report was the formation of a joint-stock company, with a subscribed capital of £8,000,000 (afterward increased), in which Saïd, the pasha of Egypt, took a large number of shares, and made large concessions of land; and the work was accordingly begun. The canal was to be dredged through lake Menzaleh, which runs far into the land directly toward Suez, to be connected with lake Temsah, the Bitter lake, and other marshy swamps, and so with Suez. Only a third of the way required to be excavated through the sands and rocks of the desert. As early as Dec., 1864, the Mediterranean and the Red sea had been connected. The communication, however, was not throughout by the permanent maritime canal, but simply by a fresh-water canal of no great width or depth. In April, 1865, the works, at the request of M. de Lesseps, were visited by another scientific commission, who reported more favorably of the scheme than was expected in England. They stated that the "construction of a ship-canal across the isthmus is only a question of time and money," and they added that three years would suffice for the completion of the various contracts connected with the undertaking.

The canal was formally opened in Nov., 1869. An account of the opening, and a description of the canal in its completed state, is given under SUEZ CANAL.

The hostility of the British nation to the canal faded away with its successful completion and the advantages which it afforded to British commerce. The fears expressed at the opening of the canal, that the trade of the east would be diverted from Great Britain as a center, were found by statistics to be as groundless. In 1875 the British government purchased, for £4,000,000, the khedive of Egypt's shares in the canal, which amounted to 176,602 out of 400,000. These shares give no returns to their owner till 1894, the khedive having alienated the dividends till that period in favor of the company.

SUEZ CANAL. In the former article on this subject, the nature of the scheme was briefly described, and illustrated by a small map; and the progress of the works noticed down to the year 1865. In this place, some of the features will receive a little further explanation, now that the canal is finished and in operation. The canal is 85 m. long.

The Port Said Entrance.—Port Said or Saïd, a t. now containing 10,000 inhabitants had no existence in 1860. It became the depot of the company, the metropolis of vast bodies of laborers and other persons employed on the works of the canal. As the Mediterranean sea is very shallow near this point, an artificial deep channel had to be made

bounded e. and w. by piers stretching far out into the sea. Stone for these piers was, in the first instance, brought from a long distance; but afterward artificial stone was made on the spot, consisting of two parts of sand and one part of hydraulic lime ground into a paste, and poured into wooden boxes or moulds. When the mixture solidified, the mould-boards were removed, and the solid blocks of artificial stone were left from three to six months in the open air to dry and harden. The blocks contain 10 cubic meters each, weigh 20 tons, and were made at a contract price of 42 francs *per mètre cube*. The western pier has a length of 7,000 ft., and the eastern of 6,000 ft.; they are 4,600 ft. apart at the shore, but gradually approach toward each other, so that their outer ends are only 2,300 ft. apart. The western pier is continued in an arc of 1100 yds. extent, so as, with the eastern pier, to shelter the harbor from all winds. Within this outer harbor is an inner port, 870 yds. by 500, which is kept at a uniform depth of 30 ft., by means of steam-dredging. The lighthouse, with its electric light, is 180 ft. high.

From Port Said to Tensah Lake.—From Port Said, the canal crosses about 20 m. of Menzaleh lake, a salt-water shallow, closely resembling the lagoons of Venice, having from 1 to 10 ft. depth of water. The canal through this lagoon is 112 yds. wide at the surface, 26 yds. at the bottom, and 26 ft. deep. An artificial bank rises 15 ft. on each side of this channel. Beyond Menzaleh lake, heavier works begin. The distance thence to Abu Ballah lake is 11 m., with a height of ground above the level of the sea varying from 15 to 30 ft. Crossing the last-named lake, there is another land distance of 11 m. to Tensah lake, cutting through ground to a depth varying from 30 to 70 or 80 ft.; and then 3 m. further across this little lake itself. At El Guisr, or Girsch, occurs the deepest cutting in the whole line, no less than 85 ft. below the surface; at the water-level it is 112 yds. wide, at the summit-level 173 yds., from which the vastness of the gap may be estimated. Ismailia (pop. 5,000) on Tensah lake, is regarded as the central point of the canal. While the canal was being made, it grew up rapidly from an Arab village to a French town, with the houses of engineers and managers, hotels, shops, cafés, a theater, and a central railway station, from which railways stretch to Alexandria and Suez.

The Fresh-water Canal.—This extends from the Nile to Tensah lake, and was constructed purposely to supply with water the population accumulating at various points on the line of the canal; but is also used by small sailing-vessels. This fresh-water or "sweet-water" canal comprises three portions or sections: (1) from the Nile e. or n.e. to Ismailia, on Tensah lake; (2) from Ismailia, nearly s. to Suez, on the w.tern side of the great ship or maritime canal; (3) from Ismailia nearly n. to Port Said, also on the w. side of the ship canal. The first and second of these sections are really canals, large enough to accommodate small steamer and barge traffic; but the third section consists simply of a large iron pipe, through which the water is conveyed to the several stations. Plugs are inserted in the pipe wherever needed, to allow water to be drawn off for every-day wants.

From Tensah Lake to Suez.—The route crosses Tensah lake to Toussoum and the Serapeum cutting, through a plateau 46 ft. above the sea, where the waters were let in by the prince and princess of Wales, Feb. 28, 1869. There is a space of 8 m. from Tensah lake to the commencement of the Bitter lakes, which had to be dug to a depth varying from 30 to 62 ft., according to the undulations of the surface. In these deep cuttings, owing to the great width of the canal, the quantity of sand to be dug out (for it is nearly all sand, though sometimes agglomerated with clay) was enormous, requiring the constant labor of a large number of powerful dredging machines and elevators. In passing through the Bitter lakes, there was more embanking than excavating to be done, seeing that the bottom of this region is only two or three yards above the intended bottom of the great canal. From the southern end of the Bitter lakes to Suez, a distance of about 13 m., there is another series of heavy cuttings through the stony plateau of Chalouf, varying from 30 to 56 ft. in depth. Where cutting is thus difficult, the surface width is reduced considerably from the regular width of 327 feet. The canal is intended throughout to be 72 ft. wide at the bottom, and 26 ft. deep.

On Nov. 16, 1869, the Suez canal was opened in form, with a procession of English and foreign steamers, in presence of the Khedive, the empress of the French, the emperor of Austria, the crown-prince of Prussia, and others. On Nov. 27, the *Brazilian* went through; a ship of 1809 tons, 380 ft. long, 30 ft. broad, and drawing from 17½ to 20½ ft. of water. Since then, the canal has continued in successful operation, and passages have been made almost daily, chiefly by British vessels. The cost of construction of the canal was said to have reached, in Dec. 1869, the total of £11,627,000. In 1870, 491 ships, of 436,618 tons, passed through; and in 1874, 1264 ships, of 2,424,000 tons. About 70 per cent of the shipping and tonnage belongs to Great Britain. The great advantage of the canal is, of course, the shortening of the distance between Europe and India. From London or Hamburg to Bombay is by the cape about 11,220 m., but by Suez only 6,332; that is, the voyage is shortened by 24 days. From Marseilles or Genoa there is a saving of 30 days; from Trieste, of 37. The rate at which steamers are allowed to pass through, is from 5 to 6 knots an hour. The canal charges are, 10 francs per ton, and 10 francs per head for passengers. The receipts for 1873 amounted to 22,755,862 francs, or £911,032; for 1875 (when 1494 ships passed through), to 28,879,735 francs, or £1,155,185; for 1876 (1457 ships passed), 31,143,762 francs (£1,245,750).

SUFFOCATION. See ASPHYXIA and RESPIRATION.

SUFFOLK, a co. in e. Mass., on Massachusetts bay, containing the cities of Boston and Chelsea, the townships of Revere and Winthrop, and some small islands in Boston harbor and Massachusetts bay; 44 sq.m.; pop. '80, 357,626. Its manufactories numbered, in 1870, 2,546, requiring \$48,000,000 capital, giving employment to 43,557 persons; the raw material used amounted to \$60,000,000, and produced \$112,000,000 in value. The county is one of the smallest in the state, and the second in population. Co. seat, Boston.

SUFFOLK, a co. in s.e. New York, bounded on the n. by Long Island sound, on the s. by the Atlantic ocean, watered by the Peconic and other rivers, traversed by the Long Island and the Southside railroads; about 850 sq.m.; pop. '80, 53,926—48,319 of American birth. It includes the central and e. portions of Long Island. The surface is level except in the north. The soil is sandy, but yields well by the use of fertilizers. The principal productions are corn, oats, wheat, wool, grass, and dairy products. The coast is indented by numerous bays, which make good harbors. There are ship-yards, flour-mills, and manufactories of cottons and woollens, paper, bricks, etc. Co. seat, Riverhead.

SUFFOLK, a maritime co. of England, bounded on the e. by the German ocean, on the n. by Norfolk, and on the s. by Essex. Area, 947,681 acres; pop. '71, 348,475. The surface is for the most part flat, falling away into marshes on the n.w. and n.e. borders. The coast-line, which is low and marshy, or lined with cliffs of shingle or gravel and red loam, is about 50 m. in length, and is, on the whole, regular, being unbroken by any considerable indentation, and comprising no headland worthy of notice except Lowestoft Ness, the most easterly point in Great Britain. The tributaries of the Waveney, which separate Suffolk from Norfolk on the n., and those of the Stour, which form the boundary-line on the s., together with the river Lark, an affluent of the Great Ouse, and the Gipping, which, after it begins to broaden into an estuary, is called the Orwell, are the chief streams. The climate is cold in spring, but is drier than that of the western counties. The soil is of various kinds, some of which are very productive. 770,000 acres are under cultivation, and the most improved system of agriculture has been introduced, together with the best and newest agricultural implements. A polled breed of cattle, of which the cows are deservedly held in high esteem, is peculiar to the county. The Suffolk pigs are a famous and most profitable breed. There are in the co. about 430,000 head of cheep, chiefly Southdowns and crosses of this breed. The ordinary crops are raised. The co. sends four members to parliament. Capital, Bury St. Edmunds.

SUFFRAGAN (Lat. *suffraganeus*, from *suffragium*, a suffrage or vote), the name given to a bishop in a province, in his relation of dependence or subordination to the archbishop, or rather metropolitan, of the province. See METROPOLITAN. In some continental churches, the name is applied to coadjutor-bishops appointed—as in the case of prince-bishops in the German empire—to assist the bishop in his own diocese.

SUFFRAGE (Lat. *suffragium*, derivation uncertain), a right to vote, and more particularly the right possessed by the citizen of a state where representative government exists to vote for a member of the legislative body.

The idea that the universal enjoyment of political suffrage is a right by natural law, is grounded on the fiction that the obligations of municipal law arise out of a social contract express or implied. In opposition to this notion it is argued that the true purpose for which government exists is the general welfare of the nation; and it is the duty of state to consider whether the suffrage may be more beneficially exercised by the many or the few. Infants, minors, idiots, and insane persons have everywhere been excluded from the suffrage, on the ground that sound judgment is necessary for its exercise. Persons convicted of crimes have been excluded, as a security to society; and also almost universally women, for reasons based on their relation to society and to the opposite sex. Like considerations of expediency, it is argued, are a ground for withholding the suffrage from those whose circumstances and station in life render it unlikely that they should form a sound judgment on political questions. It is the intelligence and enlightenment of the country that an elective legislature should represent; and in any large extension of the suffrage there is obviously a risk of the intelligence of a constituency being swamped by its mere numerical majority. A widely extended suffrage has, however, been advocated as a valuable means of educating the people to self-dependence; and several philosophical politicians of the present day, who are favorable to a large extension of the electoral qualification, propose to obviate what they regard as its otherwise inevitable evils by graduating the suffrage, so as to give each individual elector a number of votes corresponding as much as possible to his property, education, or social position. Schemes for this end, differing in detail, have been proposed by Mr. J. Stuart Mill, in his *Considerations on Representative Government* (1851); and by prof. Lorimer in his *Political Progress not necessarily Democratic* (1857), and *Constitutionalism of the Future* (1865). See REFORM, REPRESENTATION, BALLOT.

SUFISM (from *sufi* or *safi*, the Greek *sophos*, a sage; erroneously also derived from Arab. *saf* or *suf*, wool, and thus designating an individual who wears nothing but

woolen garments) designates a certain mystic system of philosophical theology within Islam. Its devotees form a kind of ecclesiastical order somewhat similar to that of the fakirs (q.v.), or dervishes, but they are mostly of a far superior stamp; and some of the greatest Persian poets, philosophers, historians, and even kings belonged to their ranks. They assume four principal degrees of human perfection or sanctity. The first or lowest is that of the shariat—i.e., of the strict obedience to all the ritual laws of Mohammedanism, such as prayer, fasting, pilgrimage, almsgiving, ablutions, etc., and the ethical precepts of honesty, love of truth, and the like. The second degree (*tarikāt*) is not attainable by all, but only by those higher minds that, while strictly adhering to the outward or ceremonial injunctions of religion, rise to an inward perception of the mental power and virtue necessary for the nearer approach to the divinity, the necessity of, and the yearning for, which they feel. The third (*hakikal* = truth) is the degree of those who, by continuous contemplation and inner devotion, have risen to the true perception of the nature of the visible and the invisible—who, in fact, have recognized the Godhead, and through this knowledge of it have succeeded in establishing an ecstatic relation to it. This state is finally sublimated into that highest and last degree (*maʾūfāt*), in which man communicates directly with the Deity. Practically, the great mass of the people take the lowest degree; the second stage is reached by the “murids,” who do not fulfill the behests of the ceremonial law because they are behests, but because they are good in themselves, knowing that virtue is good; and because it leads to truth, they adhere to it for its own sake. They give alms because the sight of poverty grieves them; their ablutions are as much due to their desire of physical purity as to that of obeying a religious injunction. The third stage is that of the *naibs*, to whom all this spiritualizing of faith applies in a still more eminent degree. And the highest stage of attainable perfection is that of the *murshid*, whose words are God’s words, pure and simple, because he is in direct and constant communion with God. He is the “sun of faith,” by whose reflected light shine the *naibs*, its “moons.” All Sufistic poetry and parlance is to be taken allegorically and symbolically. They represent the highest things by human emblems and human passions; and religion being with them identical with love, erotic terminology is chiefly used to illustrate the relation of man to God. Thus the beloved one’s curls indicate the mysteries of the Deity; sensuous pleasures and chiefly intoxication, indicate the highest degree of divine love as ecstatic contemplation; while the wine-house, of which constant mention is made, merely indicates the state in consequence of which our human qualities merge in or are exalted into those of the Deity. Founded in the 9th c. by Kāf-Mullah, this peculiar mysticism has principally struck root in Persia, and chiefly among men of genius, e.g., Hafiz (q.v.). Recently, it has been revived, with slight modifications, by Shāmil, the renowned and once formidable antagonist of the Russians, who undertook to enlist even the common soldiers, if not in the ranks of the initiated—for Sufism, in its real meaning, is very exclusive—at least of its votaries; and the very lowest among them even had a sentence given him indicative of his forming part of the sect and of the gradations that form its main characteristic. In conclusion, it may be observed that Sufism mixes up all religions and all their prophets indiscriminately in one class; and the words idolatry, unbelief, licentiousness, and the like are generally used in their reverse sense by its votaries. Their principal religious writer is Jalāleddin Rumi.

SUFFRAGE (*ante*), under the U. S. constitution is exercised by such electors in each state as have the qualifications necessary for electors of the most numerous branch of the state legislature (art. 1, sec. 2). By the XIV. and XV. amendments the states are forbidden to abridge the privileges or immunities of United States citizens (see PRIVILEGES AND IMMUNITIES), or to deny or abridge the right of suffrage on account of “race, color, or previous condition of servitude.” It seems clear that the states retain the right to impose conditions on suffrage other than those specifically prohibited in the amendments. The age of 21 is universally fixed on as that when suffrage may be exercised by male citizens; conviction for crime, insanity, and pauperism everywhere excludes. In a few states ability to read and write is required, while Rhode Island has a small property qualification. Wyoming territory allows women to vote in all local matters, and Massachusetts in 1879 passed a law allowing women to take part in the town election of school officers; some other states have similar provisions.

SUGAR (Lat. and Gr. *sacchar*-, Sans. *sarkara*, Pers. *schakar*, Arab. *sukkar* or *assokkar*, Sp. *azúcar*, It. *zucchero*, Fr. *sucrer*, Ger. *zucker*) is a general term applied by chemists to a number of neutral carbo-hydrates, possessing a more or less sweet taste, for the most part crystallizable, and produced by the vital processes going on in certain plants and animals. They are divisible into two groups, the first embracing such sugars as are capable of undergoing fermentation, and of being resolved, under the action of yeast, either directly or indirectly into alcohol and carbonic acid gas; and the second including those sugars which are not capable of being broken up by fermentation into the above-named products. The first group contains cane-sugar or sucrose, fructose or inverted sugar, trehalose, mycose, melezitose, melitose, grape-sugar or glucose (q.v.), and milk-sugar or lactose; while the second group includes inositol or inosin, sorbitol or sorbin, and scyllitol or scyllin.

Cane-sugar or *sucrose* ($C_{12}H_{22}O_{11}$), the ordinary sugar of commerce, is by far the most

important of this class of compounds; and in so far as its sweetening properties are concerned, it exceeds grape-sugar in the ratio of 5 to 2, and milk-sugar in a still higher ratio. It has a specific gravity of 1.6. It dissolves in about one-third of its own weight of cold water, producing a thick viscid syrup, and in all proportions in hot water; it is slightly soluble in absolute alcohol, but spirit of wine of specific gravity 0.830 dissolves about one-fourth of its weight. By the spontaneous evaporation of its watery solution it is deposited in four-sided rhomboidal prisms. Common loaf-sugar and sugar-candy are two well-known forms of crystallized sugar; the former consisting of a mass of small transparent crystals, and owing its dazzling whiteness to the numerous reflections and refractions which the rays of light undergo within the interior from the numberless crystals of which it is composed; while the brown color which the latter usually possesses is due to the coloring matter not having been removed from the syrup previous to crystallization. The crystals of sugar-candy are larger than those of loaf-sugar, in consequence of the slower evaporation in the former case. When crystals of sugar—as, for example, two pieces of loaf-sugar—are rubbed together in the dark, a pale phosphorescent light is evolved. If a solution of sugar be boiled for a long time it acquires an acid reaction and loses its power of crystallizing—a change which is attended by the assimilation of additional water, and the formation of the uncrystallizable inverted sugar which will be presently described. If the boiling be further prolonged the inverted sugar ($C_{12}H_{22}O_{11}$) assimilates more water, and is converted into grape-sugar ($C_{12}H_{22}O_{11} + 2Aq$), while a little formic acid and ulmin (a brown, nearly insoluble substance belonging to the *humus* group) are produced. The crystallization of sugar is also prevented by the addition of a little oxalic, citric, malic, or any of the stronger acids to its solution; and in order to check the bad effects of an acid, a small quantity of lime is usually added to the cane-juice before it is heated.

The action of different degrees of heat on sugar has been carefully studied. At about 320° sucrose fuses, and on cooling forms the transparent amber-colored solid known as *barley-sugar*, which, if kept for a long time, assumes a crystalline state, and becomes opaque. If the application of heat be continued until about 400°, the sugar loses two atoms of water, and *caramel*, which is described in the article GLUCOSE, is formed, and at a still higher temperature, the changes which sucrose undergoes are identical with those suffered by glucose. Sugar dissolves many metallic oxides when its solution is boiled with them—as, for example, freshly precipitated oxide of lead, lime, and baryta, and its presence prevents the precipitation of alkalies of various metallic oxides from their salts—the oxides of copper and of iron being thus retained in solution. Many metallic oxides are partially or entirely reduced when boiled with sugar; thus chromic acid is reduced to sesquioxide of chromium, salts of the red oxide of mercury are converted into those of the suboxide, and salts of gold give a precipitate of the reduced metal. It does not reduce alkaline solutions of oxide of copper to the suboxide (Trommer's test) unless with the aid of heat, which converts it into glucose. Under the action of certain oxidizing agents it may be converted into propionic, formic, and acetic acids. Sucrose is not *directly* capable of undergoing fermentation; but in the presence of a ferment (yeast, for example) it is converted into glucose, and in that form it readily undergoes vinous, lactic, and butyric fermentation. Its action on polarized light is described below.

This variety of sugar is chiefly obtained from the juice of the sugar-cane, but it is also abundantly present in the juices of certain species of maple and of beet-root, all of which yield this substance as a commercial product; it is also contained in sugar-grass (*sorghum saccharatum*), whose juice yields 13 per cent of sugar; in carrots and turnips, in the pumpkin, the chestnut, the young shoots of maize, in the flowering buds of the cocoa palm, and in a large number of tropical fruits. Its use as an article of diet has been already mentioned under DIET. Several articles of food contain some form of sugar in considerable quantity. In peas, there are 2 per cent of sugar; in rye-meal and wheaten bread, about $3\frac{1}{2}$ per cent; in cows' milk, $4\frac{1}{4}$ per cent; in goats' milk and in barley-meal, $5\frac{1}{4}$ per cent; in human milk, in asses' milk, ripe gooseberries, and ripe pears, about 6 per cent; in oatmeal, about 8 per cent; in wheaten flour, from 4 to 8 per cent; in beet-root, from 5 to 10 per cent; in ripe peaches, $16\frac{1}{2}$ per cent; in ripe cherries, 18 per cent; and in dried figs, upwards of 60 per cent. Although sugar is commonly regarded as a luxury, it is in reality a very valuable article of food (as, indeed, might be inferred from its presence in milk, and in both the yolk and white of eggs), since it is very rapidly digested, and supplies heat-forming or respiratory food to the system. "When, however," says Dr. E. Smith, "it is compared with wheaten flour, it is a very dear food, since three or four times more carbon will be obtained for 1d. in flour, besides nitrogen, none of which is found in sugar. It has also been proved by Messrs. Lawes and Gilbert that even its fattening properties—that is to say, its power to form fat in the system, when it is supplied in excess of the quantity which the daily wants of the body require to produce heat—are not greater than those of starch as found in the cheapest grain."—*Practical Dietary*, 1863, p. 63. In consequence of sugar being a fat-forming substance, it should be taken very sparingly in cases of excessive obesity. There are certain forms of dyspepsia in which sugar should be avoided, as exciting increased gastric uneasiness; and in diabetes, all articles of food containing or (like starch) yielding sugar, should be rigidly prohibited. Although prone to fermentation when in a

dilute state, in its concentrated form sugar possesses great antiseptic power, and is extensively employed to preserve both vegetable and animal substances from decay. The sugar naturally existing in some fruits is often sufficient to insure their preservation in a dry state, while in other cases it is added, as in preserves and jellies. A mixture of salt and sugar applied to meat, fish, etc., preserves more of the natural flavor than mere salting does. Sugar converted into caramel is much used by cooks and confectioners as a coloring matter.

Closely allied in their chemical characters to sucrose are the following comparatively rare forms of sugar: (1) *Trehalose* ($C_{12}H_{22}O_{11} + 2Aq$), so called from *Trehala*, or Turkish manna (the product of a coleopterous insect, *Larinus nubilificans*), from which this variety of sugar is extracted, differs from sucrose in the following points—it crystallizes in brilliant rectangular octahedra; contains water of crystallization; fuses at 212° , and loses its water of crystallization; is very soluble in hot alcohol; possesses about three times as great a rotatory power on polarized light; and when heated to 356° does not undergo further change. (2) *Mycose*, obtained from ergot of rye, possesses the same composition as trehalose, from which it mainly differs in crystallizing in rhombic prisms, and in exhibiting a somewhat weaker rotatory power. (3) *Melzitose* ($C_{12}H_{22}O_{11}$), obtained from larch manna, differs from cane-sugar in its less sweet taste, and in exhibiting a less powerful rotatory action. (4) *Melitose* ($C_{12}H_{22}O_{12} + 2Aq$), the chief ingredient in the Australian manna yielded by the *eucalyptus* tree, crystallizes in acicular prisms, is feebly sweet, undergoes fermentation with yeast; but yields only half as much alcohol and carbonic acid as would be obtained from an equal weight of glucose, one half of this sugar being converted into an unfermentable syrupy body, known as *eucalyn* ($C_{12}H_{22}O_{12}$).

More important than any of the above varieties, and differing from cane-sugar in a distinctive physical property, is the substance formerly known as *fruit sugar*, but now often described as *inverted cane-sugar*. The objection to the former name is, that the sugar contained in many ripe acidulous fruits, and formerly regarded as a distinct variety, is merely a mixture of cane-sugar, with more or less of the *inverted sugar* ($C_{12}H_{22}O_{12}$), which has already been noticed as resulting from the action of prolonged boiling, or of a little acid on cane-sugar. The same change occurs in many ripening fruits, in consequence of the presence of a peculiar albuminous ferment. Inverted sugar is not crystallizable, is soluble in dilute alcohol, and produces *left handed* rotation; hence its name. By chemical means, it is convertible into grape-sugar, a change which sometimes occurs spontaneously, as is seen in the gradual crystallization of the sugar in dried fruits.

Grape-sugar, constituting the hard granular sweet masses occurring in old dried fruits, such as raisins, figs, etc., has already been described in the article GLUCOSE, or GLYCOSE, under which names it is commonly known to chemists. It is also known as *starch-sugar*, because it is readily obtained by the action of a dilute acid on a hot solution of starch, and is identical with the sugar occurring in the urine in diabetes.

Milk-sugar, known also as *lactine* and *lactose* ($C_{12}H_{22}O_{12} + 5Aq$, or, according to some chemists, $C_{12}H_{22}O_{11} + Aq$), is a purely animal product. It exists in considerable quantity in the milk, especially of the herbivorous animals, and is one of the most important and essential ingredients in that secretion. It may be obtained on a large scale by separating the curd from the milk, and evaporating the whey till it is ready to crystallize; when, on the introduction of small pieces of wood, the crystals of sugar are deposited on them. These crystals are four-sided prisms of a milk-white color, and so hard that they crunch between the teeth. This variety of sugar is only moderately sweet (*vide supra*), requires about six times its weight of cold water for its solution, but dissolves readily in boiling water, while it is insoluble in alcohol or ether. If it be gradually heated to 284° , two equivalents of water are expelled, whereas, if it be suddenly heated to about 400° , all five equivalents are given off. When pure, milk-sugar is insusceptible of fermentation; but when boiled with dilute acids, it is converted into a directly fermentable sugar, in many respects very similar to grape-sugar, and to which some chemists have given the name of *lactose*, a term commonly applied to milk-sugar itself. On treating a moderately diluted acid solution of milk-sugar with yeast, this variety is first formed, and then yields carbonic acid and alcohol; if, however, decomposing matters, as, for example, casein in the act of disintegration, are present, it undergoes lactic and butyric fermentation; and hence we understand how milk after exposure for a time to the air becomes sour. The intoxicating character of the drink prepared by the Kalmucks and Tartars from sour mares' milk, is due to this indirect vinous fermentation of sugar of milk. Regarding the uses of this variety of sugar, it may be observed that it is probably the most important of the constituents of whey (which is milk deprived of the whole of its casein except a mere trace held in solution), and hence that it is the active ingredient in the *whey-cure*, which is so popular in Switzerland. (The whey in these cases is usually obtained from goats' milk.) It is also the chief constituent of the globules used in homeopathy.

The second group of sugars, namely, those which are incapable either directly or indirectly of undergoing fermentation, are of less practical importance than cane sugar, grape-sugar, or milk-sugar.

Inosin, or *inosite* (derived from the Greek *is*, gen. *inos*, muscle), is represented by the

formula $C_{12}H_{12}O_{12} + 4Aq$. It occurs as a normal constituent in the juice of the heart, and of the involuntary or unstripped muscles, and has also been found in the tissues of the lungs, spleen, liver, kidneys, and brain, and in the urine in Bright's disease and diabetes. It has been recently shown that it is identical with the substance previously known as *phasco-mannite*, which is readily obtained from the unripe seeds of the common kidney-bean (*phaseolus vulgaris*). It forms colorless efflorescent prisms, which lose four equivalents of water at about 210° . When mixed with decaying cheese and chalk, it becomes gradually converted into lactic and butyric acids. *Seyllite* is a saccharine matter closely resembling inosite, and occurring in various organs of several plagiostomous fishes, and especially in the kidneys of the rays and skate. It differs, however, from inosite in its crystalline form, and in its containing no water of crystallization. Its composition is unknown. *Sorbin*, or *sorbite* ($C_{12}H_{12}O_{12}$), derives its name from its occurring in the juice of the berries of *sorbus aucuparia*, the service tree, and may be obtained in colorless transparent rhombic octahedra. It reduces oxide of copper to the suboxide (Froemer's test), and is of a sweetish taste.

Closely allied to the sugars, but differing from them in their chemical composition (inasmuch as they do not contain hydrogen and oxygen in the proportions to form water), are *mannite* ($C_{12}H_{14}O_{12}$), obtained from *mannu*, the inspissated juice of the *fraxinus ornus*, but also occurring in celery, onions, asparagus shoots, *lunaria saccharata* and other sea-weeds, certain fungi, the juice which exudes from apple and pear trees; *dulcite* ($C_{12}H_{14}O_{12}$), the product of an unknown Madagascar tree; *quercite* ($C_{12}H_{12}O_{10}$), obtained from acorns; and *pinite* ($C_{12}H_{12}O_{10}$), from *pinus lambertiana*, a tree growing in Australia and California. All these bodies are crystalline, and sweet to the taste.

Although chemists have hitherto looked upon the sugars as organic compounds, without any recognizable radical, and from their composition have termed them *carbo-hydrates*, "the researches of Berthelot render it probable that the sugars as well as mannite, and the bodies allied to it, are polyatomic alcohols, like glycerine, for he has found that they possess the power of entering into combination with various acids, with elimination of water, in some cases yielding colligated acids analogous to the tannic, and in others furnishing neutral bodies, closely allied to the fats." Miller's *Organic Chemistry*, 2d ed. p. 72.

Among the various chemical purposes to which the phenomenon of circular polarization may be applied, we may especially mention its use in determining the quantity of any kind of sugar in solution. While some sugars give a right-handed rotation, others give a left-handed rotation, and each sugar exerts a definite amount of rotatory power. The following are the rotatory powers of the chief varieties of sugar, equal weights of each being dissolved in an equal bulk of water, and the temperature being 56° :

Cane-sugar	($C_{12}H_{11}O_{11}$)	right	$73^{\circ}8$
Trehalose	($C_{12}H_{11}O_{11}$)	"	220°
Melezitose	($C_{12}H_{11}O_{11}$)	"	$94^{\circ}1$
Mycose	($C_{12}H_{11}O_{11}$)	"	193°
Inverted sugar	($C_{12}H_{12}O_{12}$)	left	23°
Grape-sugar	($C_{12}H_{12}O_{12}$)	right	$57^{\circ}4$
Milk-sugar	($C_{12}H_{12}O_{12}$)	"	$56^{\circ}4$
Sorbin	($C_{12}H_{12}O_{12}$)	left	$46^{\circ}9$

For details regarding the apparatus to be employed, and the method of using it, we may refer to Miller's *Chemical Physics*, 3d ed. p. 204; and to a memoir by Clerget in the *Ann. de Chimie*, iii., xxvi. 175. This method has been applied to determine the amount of sugar in diabetic urine, to ascertain the quantity of sugar which remains in the unfermented state in wines, and to other similar purposes. As, however, the process is one of extreme delicacy, this method must be used with great caution.

Manufacture.—The manufacture of sugar from the sugar-cane and other sources is now one of the largest branches of human industry, but this great development is of comparatively recent date; and although there are evidences of its very high antiquity in India and China, sugar appears only to have been vaguely known to the Greeks and Romans. It is mentioned by Theophrastus as "honey in reeds;" and Lucan has the following line, which indicates a knowledge of its existence, but merely as a curious fact:

Quique bibunt tenera dulces ab arundine succos.

Its introduction to Europe appears to have been one of the results of the Crusades. The sugar-cane was grown in Cyprus about the middle of the 12th c.; it was from thence, at a later time, transplanted to Madeira, and at the commencement of the 16th c., was carried from the latter island to the West Indies. Originally, in all probability, only the sweet recent juice was known; for apparently the art of boiling it down, and forming it into raw sugar, was an invention of the 15th c.; and it was not until the middle of the following century that a Venetian discovered the art of refining sugar, which soon became established in Germany. The first refinery of which any notice exists was one in Dresden, as early as 1597; but long previous to this the subject had attracted so much attention as to be discussed in learned treatises, one of which in particular, the *Saccharologia* of Sala, in the beginning of the 16th c., shows that the clarification of the syrup by defecation was then a matter of some importance. Still, the manufacture of sugar in the

countries to which it had been introduced made but slow progress, for its use was limited by its dearness to the wealthy. The material has now, however, become one of the commonest necessities of life, and has largely conduced to the health of nations. Until 1747, sugar was supposed to be the product of the sugar-cane only, but in that year, Marggraf, a German chemist, demonstrated that it was a natural product of other vegetables, and especially of the beet-root; and half a century later, its manufacture from that source was first commenced in Silesia. A large portion of the sugar consumed on the continent is now obtained from this source. See BEET-ROOT SUGAR.

Since we have become better acquainted with the sources of our own supplies, we have learned that a large portion of the raw sugar of the East Indies received in British ports as cane-sugar is in reality made from the juice of several palms, especially that of *arcana saccharifera*, and the wild date, *phoenix sylvestris*. The juice is obtained from these plants by cutting off the male spadix when young, and from the cut portion there is for four or five months a continual flow. The liquid is at first clear, and is immediately boiled down to a thick sirup, which granulates on cooling, and constitutes, if not otherwise purified, the coarse brown sugar called jaggery, which is extensively consumed in India. More carefully prepared, it is sent to Europe with sugar made in the cane-plantations, and is only distinguished from it by well-skilled persons. If the juice is not immediately boiled, it becomes turbid, and passing into the vinous fermentation, forms the intoxicating drink called toddy.

In Canada and in the United States very much sugar is made by boiling the juice or sap of the sugar maple-tree (*acer saccharinum*). The *sorghum saccharatum*, or sugar-grass (see DURRA), and the stalks of ordinary maize or Indian corn (*zea*) yield sugar, which has lately been made so as fairly to rival the best crystallized cane-sugar (see under SUGAR-CANE).

Beet-root sugar is manufactured from the fresh-dug roots, chiefly of the varieties we call mangold-wurzel. The process (which, however, is constantly undergoing modifications) is briefly described in the article BEET-ROOT SUGAR. Beet-root yields from 7 to 8 per cent of sugar, of which only 3 to 4 per cent are of the best quality, called *melis*, 2 to 3 per cent of the second quality, called *farin*, and the remainder molasses.

The manufacture of starch-sugar is described in the article GLUCOSE.

From the beginning of the 16th c., when the sugar-cane of India was introduced to the West Indies, sugar has been one of the most important products of those islands. Careful cultivation has produced many varieties of this useful plant, some of which are better adapted than others for particular localities. The original variety introduced into the West Indies is still cultivated under the name of the *Croole cane*; but the favorite variety is the *Otaheite cane*, which is the most luxuriant grower, and gives the largest yield of juice. It is the variety chiefly cultivated in Brazil, Demerara, and Venezuela, as well as the West Indies. In many parts of the east, another admirable variety is the *Babavian or striped cane*; it was originally raised in Java, and is the favorite with rum-distillers.

The extraction of juice from the sugar-cane is effected by simple pressure. In its native country, India, there are still in use in some districts machines of the rudest construction, which are probably the same which were used a thousand years since. The Chinapatam sugar-mill consists of a mortar made by cutting down some hard-wood tree to within 2 or 3 ft. of the ground, and hollowing the top of the portion left standing in the ground into the form of a mortar. A small hole is then bored obliquely through from the bottom of the cavity to the outside, and a pipe conveys the juice into a jar. A cylindrical piece of wood, sharpened at each end, acts as a pestle, and is kept in its place with sufficient pressure by a lever and ropes. Two men are required; one has a basket supplied with small lengths of freshly-cut cane, which he places, 2 or 3 at a time, in the mortar, and, when necessary, removes the crushed ones; the other man sits on the other end of the train, balancing it, and at the same time drives oxen which are attached to the end of the beam, and keeps the movable parts of the mill constantly turning round. Notwithstanding the rudeness of this contrivance, very large quantities of sugar are made by it in India. A much better one, however, is the Chica Ballapura engine, which consists of two upright rollers, the heads of which are formed into double spiral screws, which work in one another, so that when an ox is yoked to the long curved lever and goes round, one of the upright rollers, being connected with the lever, is made to revolve, and its screw carries the other one round, but in an opposite direction. The pieces of cane are fed in by hand between the rollers, and as the juice is squeezed out, it flows down into a small hollow below the frame made to receive it, whence a small trough carries it to an earthen pot. The frame of this mill is securely fixed with stakes driven deep into the ground. In all probability, this very ancient machine has been the origin of all the most modern ones, for they all consist of rollers placed either vertically or horizontally, between which the canes are made to pass.

The mills now in general use for squeezing the juice out of the sugar-canes are very powerful machines. Some idea of the strength of those mills will be formed from the fact, that one of the rollers weighs upward of 5 tons. The axles are 12 in. in diameter, and notwithstanding that they are made of the best wrought iron, they are not secure against breakage. The manufacture of sugar has probably been carried to greater perfection in the islands of Java, Mauritius, and Cuba, than in any other parts

of the world. In Java especially, in consequence of the great extent of the plantations, the planters have been able to erect very complete establishments for the manufacture of sugar.

The following very condensed account of the process of making sugar in Java will give some idea of the operation.

The canes, freed from all loose leaves, are passed through between the rollers under the greatest possible pressure that can be brought to bear upon them. The rollers revolve only from two to four times per minute. From 100 lbs. of canes, 65 to 75 lbs. of cane-juice will be expressed. This juice, which is of a sweetish taste, and of the color of dirty water, passes direct from the mill to a small reservoir, where it usually receives a small dose of quicklime, and without delay runs off to large iron or copper vessels, heated either by a fire underneath or by steam-pipes in the liquid. As the temperature of the juice rises, a thick scum comes to the top, which is either removed by skimming, or the warm juice is drawn off from below the scum. The concentration of the juice is partly effected in a series of large open hemispherical iron pans about six to eight ft. diameter, of which five or six are placed in a row, with a large fire under the one at the end. This one fire, which runs along under the whole row of pans, is found sufficient to make two or three of them nearest the fire boil violently, and in addition, it warms the juice in the pans furthest from the fire. As the juice first enters the pans furthest from the fire, it gets gradually heated, and the vegetable impurities rise in scum to the top, and are carefully removed. As the juice is ladled from one pan to the next, it boils with greater and greater vigor as it approaches nearer the fire, until in the pan immediately over the fire it seethes and foams with excessive violence; and this seems to be essential to the successful making of sugar. It is known that the presence of all those impurities which constitute the scum interferes with the crystallizing of the sugar; and the rapid ascent of bubbles of steam through the liquid in the pans carries all impurities dispersed through the body of the liquid to the top, where they can be removed with facility. It is well known that great heat is very destructive to cane-juice; that is to say, it turns much of the crystallizable sugar into treacle or uncrystallizable sugar, but the gain arising from getting rid of much of the impurity in the cane-juice more than compensates for the destruction of part of the sugar. After the concentration has been carried to a given point, and all the scum has been got rid of, the application of a high heat, which would act with an increasingly destructive effect as the condensation became greater, is suspended, and the liquor, now of the color of turbid port wine, and of the consistency of oil, is drawn into the vacuum-pan, where the concentration is completed at the lowest possible temperature, generally about 150° Fahr. The vacuum pan is in universal use in all European sugar-refineries, and in all well-provided sugar-plantations. It is generally made of copper, of a spherical form, and from six to nine feet diameter. The bottom is double, leaving a space of an inch or two for the admission of steam between the two bottoms, and there is generally a long coiled copper pipe of three or four inches diameter above the inner bottom, so as to still further increase the amount of heating surface. This apparatus is made perfectly air and steam tight. Leading from its upper dome, there is a large pipe, communicating with a condenser into which a rush of cold water is continually passing, so as to condense all the steam or vapor that arises from the liquid boiling in the vacuum-pan. The water which is constantly rushing into the condenser is as steadily withdrawn again by pump. There is thus a constant vacuum in the pan, and, consequently, the liquid in it will boil at a much lower temperature than it would in an open pan or boiler. There is an extraordinary advantage in being able to effect the latter stages of concentration at a low temperature, for it is when the liquid becomes thick that the destructive results of a high temperature become most excessive.

As the concentration of the liquid in the vacuum-pan proceeds, crystals of sugar begin to form, and the skill of the sugar-boiler is shown by the uniformity of the crystals he produces. The boiling is commenced by filling in only about a third or fourth of the quantity the vacuum-pan will hold, and gradually adding more liquid as the crystals increase in size. The sugar-boiler is able to watch the changes going on in the vacuum-pan by means of small samples he withdraws from it by means of a suitable apparatus. The sugar-boiler holds those drops of thick fluid on his finger and thumb, between his eye and a strong light, and is thus able to detect those minute changes in its condition which show that it is time to add an additional quantity. By the time the vacuum pan is full, the contents have thickened, by the formation of crystals of sugar, into a mass of the consistency of thick gruel; it is then allowed to descend into a vessel called the heater, where it is simply kept warm until it can be run out into the "forms," which, in the sugar-growing colonies, are generally conical earthen pots, holding from one to two cwt. of sugar. It is allowed to cool and complete its crystallization before the plugs, which close the bottom of the pots, are withdrawn. When this is done, from one-fourth to one-third of the contents of the forms, which has remained in a fluid state, runs off into gutters leading to large tanks, from which it is again pumped up into the vacuum-pan, and reboiled, yielding a second quality of sugar. This reboiling of the drainings is repeated, with a continually decreasing result, both as to quantity and quality of the solid sugar obtained, and it is rarely carried beyond the fourth boiling. If the planter wishes to obtain Muscovada or unclayed sugar, the process is now complete, and the sugar is turned out of the forms, and packed for shipment. In some cases, the sugar is

run direct from the vacuum-pan into casks or hogsheads, which replace the forms, holes being bored in the bottoms of the casks, to admit of the uncrystallized portion of the sugar draining out.

If *clayed* sugar is to be made, the forms are allowed to stand for a few days until all the treacle has drained out; and a quantity of thin mud, about the consistency of good thick cream, is then poured over the sugar to the depth of one or two inches. The water contained in this thin mud slowly steals down through the sugar, and mixing with the coatings of treacle still adhering to the outsides of the crystals of sugar, renders them less viscid, and facilitates their descent to the bottom of the form. The mud remains, at the end of a few days, in the form of a dry hard cake on the top of the sugar, and none mixes with the sugar.

The process of claying sugar is simply washing off a coating of black or yellow treacle from a crystal of sugar, which is always white. This operation is possible without dissolving the crystal of sugar, simply because the treacle has a greater affinity for water than the crystallized sugar has. Anything that would yield a very slow and steady supply of water to the sugar, would do as well as mud or clay. There is always some loss of crystallized sugar in the process of claying, and attempts have been made to use strong alcohol for washing off the coatings of treacle from the crystals; but although alcohol dissolves treacle very freely, and scarcely acts on the crystals at all, still it has not been found to answer commercially. Besides the cost of the process, there is a difficulty in getting rid of the smell of alcohol in the sugar.

The centrifugal machine of Messrs. Manlove, Alliott & Co. has been very extensively used for getting rid of the treacle. Its action depends on precisely the same principle as that called into play when a sailor twirls a mop to expel the water from it. The centrifugal machine is simply a drum of 3 or 4 feet diameter, and 12 to 18 inches high, revolving at a great velocity on a vertical axis. The sugar, either direct from the vacuum-pan or after it has been allowed to cool, is put, still mixed with the treacle, into the machine. As soon as the drum acquires a high velocity its contents are forced by the centrifugal action against the drum, the cylindrical portion of which is made like a sieve, and admits of the escape of the treacle, but retains the crystals of sugar. Some idea of the efficiency of these machines may be formed when it is stated, that in a machine of 3 ft. diameter, revolving at the usual speed of 1000 revolutions per minute, the tendency of the treacle to escape will be 514 times its own weight; that is to say, the treacle will have 514 times more force to fly off than it has to drop off the crystal by the mere force of gravity.

Sugar-refining was unknown to the ancients, and even the refining previously referred to as having been established in Germany in the 16th c. consisted merely in clarifying the sirup, and producing a sort of sugar-candy; but one improvement followed another, until the process may now be considered as almost perfect. The chief difficulties attending the operation arise from the circumstance that the material to be operated upon is ever varying in quality. Not only is there a difference between the produce of two different plantations, but even the manufacture of the same plantation shows differences of quality; these differences arising chiefly from the presence of foreign substances, which seriously interfere with the operations of the refiner. The attempts made to test the exact quality of solutions of raw sugar by means of polarized light (see above) have hitherto been attended with little success in practice. Sugar-refining, as practiced in Britain, has three distinct objects—(1) the production of loaves of thoroughly refined sugar; (2) crushed sugar; and (3) white sugar in separate crystals. The last is of comparatively recent introduction. In some existing sugar-refineries, old fashions still prevail; but our description must be confined to the most recent methods.

Sugar refining is carried on in this country on a great scale; London, Bristol, and Greenock being the principal seats of the trade. There is comparatively little raw sugar used in Great Britain. Nearly all the yellow and dark-colored sugar sold in the shops has passed through the hands of the refiners, and is simply inferior sugar, made out of the sirup which drains from the white loaf-sugar.

Sugar-refineries are built eight or nine stories high, and the raw sugar is first hoisted to the upper story, where it is dissolved in large tanks of hot water, care being taken to use as little water as possible for the purpose. A quantity of bullock's blood is stirred into the solution of sugar, and the heat being gradually raised, the albumen of the blood conglutates, and rises to the surface in the form of a thick light scum, bringing with it nearly all the mechanical impurities floating in the fluid. The liquor, still hot, is then passed into bag filters. These filters are made of a very closely woven cotton cloth, capable of retaining the minutest mechanical impurity. In order to facilitate the passage of the liquor through the bags, they are suspended in a kind of iron closet, and surrounded by an atmosphere of steam to keep the liquor hot. From the bag-filters the liquor, now freed from all mechanical impurities, but of a dark color, flows into a lofty cylindrical iron filter, of about 5 or 6 ft. diameter, and 20 or 30 ft. high, filled with animal charcoal, that is, charcoal made of bones. This charcoal is reduced to coarse powder; and the dark offensive liquor is allowed to percolate very slowly through the mass. The result is, that it flows out at the bottom a perfectly transparent and pure solution of sugar. The charcoal can only be used for a few days at a time, because it gradually loses its purifying power; when the liquor begins to flow through it without

being purified, it is taken out of the filter, and reburned, which completely revives its powers.

The liquor as it flows from the charcoal filter is a mixture of pure sugar and pure water, and perfectly transparent. The application of heat is the only mode of expelling the water, and this unfortunately blackens the sugar again. In order to get rid of the water with as little heat as possible, the colorless liquor is boiled in the vacuum-pan as in the early process of the manufacture. The liquor boils in vacuo at about 150° F., and even this moderate heat has the effect of turning it quite brown. When it has been sufficiently concentrated by boiling in the vacuum-pan, which takes from 1½ to 2½ hours, it is run into the sugar-loaf forms; which, after cooling, are carried to a room kept warm by means of steam-pipes. This warmth facilitates the flow of the treacle or syrup out at the aperture at the bottom of the form. To get rid of the coating of colored treacle which still hangs about the crystals of sugar, a small quantity of a saturated solution of pure white sugar is poured on the top of the form. This strong liquor is unable to dissolve any more sugar, but being more fluid than the sticky coatings of treacle or syrup adhering to the crystals, it mixes with the coatings, and makes them fluid enough to flow down to the bottom of the form, leaving the crystals clear of syrup or treacle, and consequently free of all color. This process of washing off the coloring matter from the crystals of sugar is the same in principle as the "claying" used in the production of sugar. The loaves of sugar, after standing some time, to admit of all the liquor draining off, are wrapped in paper, and dried in stoves heated by steam. The liquor draining from the forms is reboiled in the vacuum-pan, and forms loaves of an inferior quality; and the liquor draining from the inferior loaves is again boiled into the yellow sugars known among sugar-refiners as bastards.

Crushed or crashed sugar is simply inferior loaves crushed while still soft and moist, and packed in hogsheds, instead of being left in the loaf form.

The syrup which drains from refined sugar is reboiled, and constitutes the *golden syrup* of the shops.

Crystal Sugar.—In making the sugar crystals, all the processes are carried on as in refining, until the syrup is clarified. Then it is boiled or concentrated in a vacuum-pan of larger size than ordinary, and the concentration is carried on until minute crystals appear. Fresh syrup is then added from time to time, great care and experience being required to insure a regular feeding of the first-formed crystals, and prevent the formation of a second crop. When the crystals are large enough, the contents of the pan are transferred to the centrifugal machines, which quickly separate the crystals in a perfectly dry state from the uncrystallizable syrup. The crystals are of a square tabular form, with a deep groove across in one direction, dividing the crystal into equal parts. This kind of sugar is much liked for coffee, etc., but the crystals dissolve with difficulty.

The commerce in sugar is prodigious, and is rapidly increasing; but its consumption is very unequally distributed. Thus, in the six principal countries, America consumes the most, and Russia and Austria least. The proportions are as follow: Great Britain, 30 lbs. per head; France, 4 lbs.; Belgium, 6 lbs.; Russia, 1½ lbs.; Austria, 1½ lbs.; United States of America, 40 lbs. The quantity of all kinds imported into Great Britain in 1877 amounted to the enormous sum of 831,047 tons unrefined; 171,492 tons refined; and 14,913 tons of molasses; the total value of all of which was £27,327,988.

SUGAR-CANE, *Saccharum*, a genus of grasses, natives of tropical and sub-tropical countries. The common sugar-cane (*S. officinarum*) is originally a native of the East Indies, was brought to the S. of Europe by the crusaders, and in the 15th and 16th c. found its way into all the European colonies within the tropics. In Europe the cultivation of the sugar-cane has always been very limited, and is scarcely practiced except in Sicily and Andalusia. In China it extends to 30° n. lat., and in North America to 32°; in the southern hemisphere only to 22° s. lat. The plant is a perennial with a creeping root, sending up a number of culms or stems, generally 8 to 12 ft. high, which have many joints, are of various colors, and about 1 to 2 in. thick. They are filled for about two-thirds of their length with a loose, sweet, juicy pith. The leaves are ribbon-shaped, and 4 to 5 ft. long, with a strong whitish middle nerve. The flowers are in great diffuse pyramidal panicles of a yard in length. The violet-colored sugar-cane (*S. violaceum*) is particularly esteemed, and much cultivated in the West Indies.—The Chinese sugar-cane (*S. sinense*), cultivated in China, has the stem in great part covered with the sheaths of the leaves. Cultivation has produced many varieties of these species; if, indeed they are originally distinct species, and not themselves mere varieties.—The species of *saccharum* are numerous; they contain much silica in the rind, and some of them are much employed in India for thatching and for making mats, as well as for screens and light fences. The Bengalese make their pens of the hollow stems of *S. semidecumbens* and *S. fuscum*.

The sugar-cane is usually propagated by cuttings. For this purpose the top joints are used. The cuttings are planted in rows 3 or 4 ft. apart, and at intervals of about 2 ft. in the rows. The largest varieties, in rich moist soils, attain a height of 20 ft.; but in dry poor soils, the height is sometimes scarcely more than 6 feet. The plant *tillers* like wheat, but not to the same degree. The cane-ground is kept clean by hand-hoeing, or by the plow. Hand-hoeing was formerly universal in the West Indies, but the plow

is now very generally used where the nature of the ground permits. The best varieties are ready for cutting in about ten months from the time of planting, but other varieties require a longer period of growth, from 12 to 20 months. When the canes are fully ripe they are cut a little above the ground, and tied in bundles to be conveyed to the mill. Fresh canes called *rattoons* spring from the root, so that the plantation does not require to be renewed for several years; but the canes of the first crop are the largest, and a gradual decrease of size takes place. The ordinary practice on sugar estates is to renew a part of the plantation every year.

The name **CHINESE SUGAR-CANE** is sometimes given to the **SHALOO** or **SUGAR-GRASS** (*sorghum saccharatum*), already noticed in the article **DURRA**. A still more important sugar-yielding grass is the ordinary maize or Indian corn. The sorghum became known in America in 1857, and has latterly been extensively cultivated for producing syrup. It has long been known that sugar could also be obtained from the stalks of maize; but neither sorghum sugar nor maize sugar could till lately be made so as to compete commercially with the produce of the sugar-cane. Recently, however, an American gentleman—Mr. Stewart, of Murraysville, in Pennsylvania—has discovered a method of obtaining from both sorghum and maize crystallized sugar equal to the best kinds known. The processes are somewhat simpler than those in use for the sugar cane, and are more economical than those employed in making beet-sugar. The quantity is also abundant. It has been calculated that, on an average, one acre of maize may yield 1800 lbs. of sugar and 44 galls. of molasses; and that the yield of sugar from one acre of maize will give as good a profit as could be got from 30 acres of wheat. (See report of Mr. Drummond, British secretary of legation at Washington in 1878.) Two per cent of the area now given to maize would serve to supply the enormous demand for imported sugar in the United States. It is therefore easy to see how great would be the effect produced in the sugar trade of the world if the United States were to utilize for their own use, as they may now easily do, their own sugar supplies; still more if they should become a sugar-exporting country.

SUGAR-OF-LEAD, the common name for acetate of lead. See **LEAD**.

SUHL, a t. of Prussia, province of Saxony, and government of Erfurt, is situated on a small stream, called the *Lauter*, in a romantic valley on the s.w. side of the Thuringian forest, 32 m. s.s.w. of Erfurt. The name *Suhl*, which in the Sorb-Wendish dialect means salt, is probably derived from the salt springs, formerly much worked. Mining is extensively carried on in the neighborhood, and has been so for centuries. The principal manufactures are iron and steel wares, chemical preparations, paper, and leather. *Suhl*, celebrated in the days of chivalry as the "arsenal of Germany," still maintains its ancient reputation as a manufactory of arms. Pop. '75, 10,721. Its history is very interesting; see Werther's *Sieben Bücher der Chronik der Stadt Suhl* (1847).

SUHM, **PETER FRIDERIK**, a Danish historian, was b. in Copenhagen, Oct. 18, 1728, of an ancient and noble family, and was sent to the university of Copenhagen, where he graduated in law in 1748. A few years later he went to Norway for the sake of prosecuting his studies in philology and history, in conjunction with the learned historian *Schöningh*, and did not return till 1765 to Copenhagen, where he continued to reside till his death in 1798. Among his numerous works on the early mythical and political history of Denmark we may instance the following: *Forsoeg til Forbedringer i den gamle danske og norske Historie* (1757); *Om de nordiske Folks ældste Oprindelse* (1770); *Om Odin og den hedenske Gudelære* (1771); *Critisk Historie af Danmark i den hedenske Tid*, i.-iv. Baud (1774-81); *Historie af Danmark*, 1ste *Tome* (1782). Besides numerous other historical essays, moral treatises, poetic compositions, contributions to the philosophical and literary periodicals of Germany, France, and Denmark, etc., he edited *Scriptorum Rerum Danicarum Mediæ ævi*, from vol. iv. to vol. vii. inclusive (Hafniæ, 1776-92), and took upon himself the cost and supervision of the publication of many remains of old northern literature. *Suhm* was an indefatigable collector of rare and curious books; and in 1793, in return for a pension from the government, he made over to the royal library of Copenhagen his valuable library of 100,000 volumes, to which he had previously allowed the public access. After the death of his only son he devoted the greater part of his ample means to the purpose of having copies made of the more valuable MSS. in the collection, many of which were, moreover, printed at his sole charge; besides which he founded scholarships and afforded direct pecuniary assistance to many poor students and learned men. He died in 1798. *Suhm's* collective writings were brought out by S. Poulsen, in 16 vols., between 1788-99; and various editions of his lesser works have at different times appeared in Germany, as well as in Denmark, where he is justly regarded as one of the most learned and laborious and patriotic writers of his country.

SUICIDE (Lat. self-murder) is a heinous crime, by the law of the United Kingdom, though it was treated as venial by the Roman law, and was the subject of panegyric by Stoic philosophers. The law of England treats it as a felony, and hence there may be accessories to it, so that if A persuade B to kill himself, and B does so, A is guilty of murder. Suicide, or *felo de se* (q.v.), not only includes one who deliberately kills himself, but also one who in maliciously attempting to kill another is himself killed. If A, however, requests B to kill him, and B does so, A is not a *felo de se*, though B is a murderer. If A and B mutually agree to commit suicide together, and in the attempt one

only dies, the other is guilty of murder. When it is said that a man was a suicide, this implies that he was in his senses, for otherwise he committed no crime; hence an insane person, unless when in a lucid interval, cannot commit the crime. The punishment inflicted on a suicide consisted, formerly, in an ignominious burial in the highway, with a stake driven through the body, and without Christian rites, also the legal consequence was forfeiture of the goods and chattels to the crown. The only consequences now are forfeiture of goods and deprivation of Christian rites. The burial now takes place in a churchyard, but between 9 and 12 p.m. An attempt to commit suicide is not punishable like an attempt to murder a third party, nevertheless it is a misdemeanor. The consequences of suicide on the contract of life-assurance are generally guarded against by an express stipulation that, if the assured die by his own hand, the policy shall be void; and it has been held by the courts that the policy is forfeited even though the party destroyed himself in a fit of frenzy or delirium.—In Scotland suicide is also followed by forfeiture of the movable estate to the crown.

There are, no doubt, even in modern times, some who hold the theoretical opinion that suicide is permissible in certain circumstances, but in regard to those who have actually permitted or attempted the crime, there has almost always been detectable evidence of cerebral changes, or, at all events, of that irritation and excitement which initiate and accompany molecular disorganization of the nervous structure. In short, suicide, as a rule, is a symptom of some form of insanity, permanent or temporary, in which the emotions and passions are excited or perverted. Suicide is likewise a concomitant of certain bodily diseases; for example, of dilatation and fatty degeneration of the heart, of blood degeneration, of affections of the intestinal mucous membrane, of the uterus, and of the brain and nervous matter; and it may be regarded as a frequent sequence of the melancholic, the morose, and hypochondriacal temperament. It has appeared as an epidemic; it has been observed as a hereditary tendency in certain families, and as a tendency more frequently exhibited by males than females; more frequently by the educated and affluent than by the industrial and ignorant classes; most frequently in large cities, and as directly engendered by luxury, political agitation, gambling, intemperance, and demoralization. It would appear, however, that indulgence and asceticism, riches and extreme poverty, claim nearly an equal number of victims. It has been calculated that twice as many artisans commit suicide as laborers. In 1840, it was found that in every 10,000 of the population, 1.33 masons, carpenters, butchers; 7.43 tailors, shoemakers, bakers; 4.9 bankers, professionals; 2.0 of persons assured in equitable office; 7.8 dragoons; 6.7 servants and coachmen; 4.0 paupers, died by their own hand. Observation has shown that from 20 to 35 is the most influential age in inducing the suicidal tendency, and the age appears to determine, to a certain degree, the modes of death selected as well as the proclivity. As might be expected, the nature of the delusion, the accessibility of the means, imitation, the profession or pursuit of the individual, novelty, and notoriety, all influence the choice of the instrument or means of death. The theomaniac dies by crucifixion; the great majority by ropes, rivers, wells, razors, arsenic; the medical man by aconite, chloroform. Even sex is characterized by peculiar preferences. Females seek voluntary death according to the following order of the means—hanging or strangulation, abstinence, precipitation, drowning, cutting, poison; males, again, according to this order—cutting, shooting, hanging, poison, drowning. Race, climate, country, and the distinguishing polity of different societies to a certain extent affect the proportion of suicides to the population. In the kingdom of Sweden there is calculated to be 1 suicide to every 92,375 inhabitants; in Saxony, 1 to 8,446; in Russia, 1 to 34,246; in the United States, 1 to 15,000. In Paris, 1 suicide occurs in 2,700; in St. Petersburg and London, 1 in 21,000 citizens. Middlesex, again, is the most prolific of all English counties; Chester least so; there being in the former 10.5, in the latter 7.2 to 100,000 people. In all England, the proportion is 7.4.—*Anatomy of Suicide*, Forbes Winslow; *Du Suicidé et de la Folie Suicidé*, etc., a Brière de Boismont; *Traité du Suicide*, Louis Bertrand; *English Suicide Fields*, Radcliffe, p. 701; *Medical Critic*, 1862.

SUIDÆ, a family of mammalia, of the order *Pachydermata*, having the feet generally four-toed, the hinder feet some times three-toed; the toes hoofed, the two front toes forming the principal part of the foot, the others smaller and scarcely touching the ground; the snout abruptly truncated, mobile, muscular, and sensitive, but not elongated into a proboscis; the tail short, or almost wanting; the incisor teeth variable in number, the lower ones all directed forward, the canines projecting, and bent upward; the stomach little divided. To this family belong hogs, wart-hogs, peccaries, etc.

SUIDAS, the name given by the compiler of a *Lexicon* some time during the Byzantine empire. When he lived, or who he was, or whether he was even called Suidas, no one can say, but it is customary to place him about the 10th or 11th century. The *Lexicon* bears unmistakable evidence of having gone through many hands; and though we can fix the date when several of the articles *must* have been written, it is impossible to ascertain whether they are the compositions of the first compiler or of a later editor. The work is a sort of cyclopedia, giving an explanation of words, and notices of persons, places, etc., in alphabetical order. It is utterly destitute of literary or critical merit, but is valuable in the eyes of scholars on account of its numerous extracts from ancient Greek writer, grammarians, scholiasts, and lexicographers, whose writings in many

cases have perished. The first edition appeared at Milan (1499): since then the best editions have been those of Küster (Camb. 3 vols. 1705), Gaisford (Oxf. 3 vols. 1824) Bernhardy (Halle, 2 vols. 1834), and J. Bekker (Berl. 1854).

SUI JURIS, in the Roman law, the condition of a person not subject to the *Patria Potestas* (q.v.). The paterfamilias was the only member of a family who was *sui juris*, all the rest being *alieni juris*, including sons, unmarried daughters, the wife, and the wives and children of the sons of the paterfamilias. A daughter, on her marriage, passed into the family of her husband, but a son did not become *sui juris* by marriage. A son or unmarried daughter became *sui juris* on the death of the paterfamilias. In his father's lifetime a son could only become *sui juris* by emancipation. The laws of the twelve tables declare that a son three times sold by his father should be freed from his power; and the ceremony of emancipation was of the nature of a fictitious sale gone through three times, in order to liberate the son from parental control. *Connubium* being the foundation of the *patria potestas*, a bastard was *sui juris*.

SUIR, a river of Ireland rising in the n. of the county of Tipperary, flows s. through that county by the towns of Thurles and Cahir; 10 m. s. of Cahir it bends eastward, forming the boundary of Tipperary and Waterford, and passing by Clonmel and Carrick. It then passes out of Tipperary, and meeting the Barrow at Passage, Waterford, falls into the sea in Waterford Haven, after a course of about 100 m. It is navigable by barges as far as Clonmel.

SUIT IN CHANCERY was the process corresponding to an action in a court of law. The suit generally commenced with a bill, i.e., a petition to the lord chancellor, which set forth the grievance, with a prayer for redress. It was signed by counsel, and was served on the defendants, either personally or at the dwelling place. They had then to enter appearance, and put in either an answer or a demurrer, or a plea, which were the several defenses to the suit, according to the nature of the subject matter. Since 1876, all suits have been called actions, but the procedure is not much changed. An appeal lies from the chancery division of the high court to the court of appeal, and finally to the house of lords.

SUL, RIO GRANDE DO. See RIO GRANDE DO SUL.

SULIMAN' MOUNTAINS, a mountain range upward of 350 miles in length, running from n. to s., and forming the boundary between Afghanistan and the Punjab. In lat. about 33° 20', it throws off the lateral branch of the Salt Range (q.v.). The highest summit of the range is Tacht-i-Suliman (Solomon's throne), 11,000 ft. high, and covered with snow for three months of each year.

SULINA, one of the lower branches of the Danube (q.v.), flows through the middle region of the delta of the great river, and enters the sea at about the same distance from the Kilia mouth on the n. and St. George's mouth on the south. It is the smallest outlet of the Danube, and conveys only $\frac{2}{3}$ of the main river to the sea; but its channel through the bar that lines the coast is deeper than that of the other mouths, and therefore the Sulina is more frequented by vessels than any other branch of the Danube.

SULIOTS, a tribe who inhabited the valley of the Achéron, in the pashalik of Janina (*Epirus*) in European Turkey, are a mixed race, being partly of Hellenic and partly of Albanian origin. They are the descendants of a number of families who fled from their Turkish oppressors to the mountains of Suli (whence they derive their name) during the 17th century. In this obscure corner of the Turkish empire they prospered; and toward the close of the 18th c., numbered 560 families, inhabiting 90 hamlets. For about 51 years they heroically resisted the encroachments of Ali Pasha (q.v.) of Janina upon their independence, the very women taking part in the strife. Vanquished in 1803, they retreated to Parga, and afterward to the Ionian islands, where they remained till 1826, when their old oppressor, Ali Pasha, finding himself hard pressed by the Turks, invoked their aid, offering them guarantees for his faith, and his grandson as a hostage. Eager to return to their cherished home, they accepted these terms, and under Marcos Bozzaris (q.v.), maintained a long and desperate conflict with the Turks, but were ultimately forced again to flee from their country, and take refuge to the number of 3,000 in Cephalonia, though a large remnant preferred to skulk in the neighboring mountains. Though they took a glorious part in the war of Greek independence, their country was not included by the treaty of 1829 within the Greek boundary-line; but most of them established themselves in Greece, where their leaders were raised to important offices. The old seat of the Suliots lies in a portion of Epirus which the Berlin congress of 1878 recommended to be restored to Greece.—See Perriarbo's *History of Suli and Parga* (2d Greek ed., Venice, 1815; Eng. trans. 1823); and Ludmann's *Wars and Ballads of the Suliots* (Leip. 1825).

SUL'LA, L. CORNELIUS, surnamed by himself FELIX, the ablest Roman after the younger Scipio until the appearance of Julius Cæsar, was b. 138 B.C. His family was a member, but not a distinguished one, of the Cornelian *gens*, or "clan." In 107 B.C., he was elected questor, and sent to Africa with the cavalry that the consul Marius (q.v.) required for prosecuting the Jugurthine war. He rapidly acquired a brilliant reputation as an officer, and crowned a series of important services by inducing Bocchus, the Mauritanian king, to surrender Jugurtha, whom he brought in chains to the Roman

camp (106 B. C.). Marius was not over well pleased at the distinction achieved by his subordinate. In the campaigns that followed (104-101 B. C.) against the Cimbri and Teutones, Sulla's reputation continued to rise, although Marius was still regarded (and with justice) as the first general of the state. For several years after the destruction of the barbarians, Sulla lived quietly, taking no part in public affairs; but in 93 B. C. he stood for the pretorship, and won it by a liberal distribution of money among the people. Next year, he was sent to Cilicia as propretor, to replace Ariobarzanes on the throne of Cappadocia, from which he had been driven by Mithridates. On his return to Italy (91 B. C.), the long smoldering animosity between Marius and him was on the point of bursting forth, but the terrible *social war* forced all Romans to postpone their quarrels until the common danger had been averted. Both Marius and Sulla commanded armies in this great struggle; but the successes of Sulla threw those of Marius into the shade, and the mortification of his rival was deep and bitter. In 88 B. C., Sulla was elected consul along with Q. Pompeius Rufus, and the senate conferred on him the command of the Mithridatic war. But this was a command that Marius himself passionately desired, and when he heard that Sulla had obtained it, he rushed headlong into treason and civil war.

Here it may perhaps be necessary to observe that Marius and Sulla were not only personal rivals, but the leaders of opposite political parties. The former, a man of humble origin (see *MARIUS*), was a rough, stubborn, irascible, and illiterate *plebeian*; the latter, a finely cultivated *patrician*, subtle and sagacious in policy, and winning in manners. In the terrible scenes that ensued, although Sulla showed himself by far the fiercer and more sanguinary of the two, it should not be forgotten that it was Marius who commenced the contest. Allying himself with the tribune P. Sulpicius Rufus, a political adventurer in difficulties, Marius placed himself at the head of the new Italian party, on which the rights of Roman citizenship had been conferred, and hoped to force the senate to recall the appointment of Sulla to the command of the expedition to the east. Sulla was compelled to flee to Nola in Campania, where his camp then was; but finding the soldiers full of enthusiasm, he resolved to lead them against the pseudo-government that had been established at Rome. The story of the overthrow of the Marian party, the expulsion of Marius, and his subsequent wanderings in Africa, etc., are well known, and intimately as these events are involved with the fortunes of Sulla, cannot be repeated here. Suffice it to say, that after settling affairs at Rome as well as he could, Sulla embarked for the east (87 B. C.), and was away for four years. Most of his fighting, however, was done in Greece against Archelaus, an ally of Mithridates, whom the latter repeatedly subsidized with men and money. Athens was stormed and plundered (86 B. C.), and Archelaus himself was defeated with frightful slaughter at Chæroneia in the same year, and again in the neighborhood of Orchomenos (84 B. C.). Sulla now crossed the Hellespont, crushed Fimbria, a general sent out by the Marian party (which in Sulla's absence, had again got the upper hand in Italy), forced Mithridates to sue for peace, and after extorting heavy contributions from the cities of Asia Minor, sailed for Italy, and landed at Brundisium in the spring of 83 B. C. Marius was now dead, but his party were strong in numbers, if not in organization; yet, before the close of 82 B. C., the Marian party in Italy was utterly crushed. In Spain, however, under the gallant and high-souled Sertorius (q. v.), it held out for ten years longer.

When Sulla felt himself master of the situation, his thoughts turned to revenge. Then followed the fearful period of the *proscriptions* (81 B. C.)—a virtual "reign of terror" throughout Italy, the object of which was literally to extirpate the Marian party. In this, however, it was only partially successful; and the next generation saw that party rise to more splendid predominance than ever in the person of Julius Cæsar (q. v.), nephew of old Marius. In 81 B. C., Sulla got himself appointed dictator, an office which he held until 79 B. C. This period was signalized by his framing a series of laws—often spoken of collectively as the "*Sullan legislation*"—the design of which was to make the senate and the aristocracy as vigorous and powerful as in the times of the Punic wars, but which utterly failed of its end.

On resigning his dictatorship, Sulla retired to his fine estate at Puteoli, to enjoy at his ease those sensual pleasures to which he had been deeply addicted from his earliest manhood. Literature, wine, and women were luxuries in which he had always indulged, but now he wholly devoted himself to them—in a sort of *swinish* manner. It is strange to reflect that the man who undertook to legislate with the view of mending the public morals, should himself have surpassed in profligacy all his contemporaries. What more convincing proof could we have that morality in Rome had ceased to be more than a name! Sulla's debaucheries hastened his end. He died 78 B. C., when only 60 years of age, of the disgusting disease known as *morbus pediculosis*.

SULLIVAN, a co. in s. w. Indiana, having the Wabash river for its w. boundary separating it from Illinois; 435 sq. m.; pop. '80, 20,336—19,944 of American birth, 146 colored. It is intersected by the Evansville and Terre Haute railroad; drained by the Wabash and Busseron creeks. Its surface is level, with a good supply of timber and groves of hickory and sugar maple. It has extensive beds of bituminous coal. Stock is raised in large numbers, and the soil is adapted to the production of grain, maple sugar, sorghum, and dairy products. Its manufactures are lumber and cooperage. Co. seat, Sullivan.

SULLIVAN, a co. in n. Missouri, crossed by the Burlington and South-western railroad, and drained by Muscle river, the e. fork of Medicine creek, and the middle and w. forks of Locust creek; 648 sq.m.; pop. '80, 16,569. The surface is partly rolling prairie, and partly forest; the soil is fertile. The principal productions are grain, hay, tobacco, wool, and lumber. Horses, cows, mules, sheep, and swine are raised in great numbers. It contains flour and saw mills, and cloth dressing and wool carding are carried on. Bituminous coal is found here. Co. seat, Milan.

SULLIVAN, a co. in w. New Hampshire, bounded by the Connecticut river on the w., and partly by Lake Sunapee on the e., intersected by the Concord and Claremont railroad, drained by the Ashuelot and Sugar rivers; 850 sq.m.; pop. '70, 18,508. The surface bordering the Connecticut is level, other parts of the county consists of rugged hills, covered with forests of oak, ash, sugar maple, and elm trees, and are suitable for grazing; the soil is mostly fertile. The principal productions are grain, hay, potatoes, wool, butter, cheese, and maple sugar. Cattle, horses, sheep, and swine are raised in large numbers. It contains manufactories of cotton, woolen, paper, machinery, boots and shoes, and wooden ware, and tanned and curried leather establishments, also flour and saw mills. Co. seat, Newport.

SULLIVAN, a co. in s.e. New York, having the Delaware river for its w. and s.w. boundary, separating it from Pennsylvania; 980 sq.m.; pop. '80, 32,490—28,230 of American birth, 84 colored. It is drained by the Mongaup, Neversink, Beaver Kill, and Shawangunk rivers, and Rondout creek. It is intersected by the Delaware and Hudson canal; the Erie railroad in the w. and s.w. following the course of the Delaware river, and the New York and Oswego Midland railroad. A branch of the Erie railroad connects its co. seat with Port Jervis. The surface is mountainous, traversed by several lofty ridges divided by fertile valleys. Leather, carriages, and lumber, are manufactured. Co. seat, Monticello.

SULLIVAN, a co. in n.e. Pennsylvania, drained by the Susquehanna river, Loyalsock and Muncy creeks; 420 sq.m.; pop. '80, 8,073—7,151 of American birth, 3 colored. The surface is hilly and includes a part of the Alleghany mountains. It is well timbered with oak and hickory, and an occasional grove of sugar maples. Coal is found, and the soil is adapted to stock raising and the production of grain, potatoes, and dairy products. Leather and lumber are manufactured. Co. seat, Laporte.

SULLIVAN, a co. in n.e. Tennessee, bordered by Virginia, crossed by the East Tennessee, Virginia and Georgia railroad, drained by the Holston river and its branches; 300 sq.m.; pop. '80, 18,321. The surface is hilly and partly covered with forests of sugar maple, beech, oak, ash, chestnut, hickory, and pine. The soil is fertile; the principal productions are wheat, corn, oats, flax, wool, honey, tobacco, maple sugar, and sorghum molasses. It contains large deposits of iron ore and limestone. Co. seat, Blountsville.

SULLIVAN, ARTHUR S., b. England, 1844. He sang as a choir boy in St. James's chapel royal of London, and then studied music in Germany. After his return to England he composed the music to *Cor and Bore*; *The Prodigal Son*; *The Light of the World*; and *Trial by Jury*. His music to Shakespeare's *Tempest* won a great success, and his songs and sacred music have placed him among the leading composers of the day. He is best known, however, as the composer of the comic opera *Pinafore*, for which W. S. Gilbert wrote the words. It was first produced in England, but failed to make the extraordinary but ephemeral success it attained on its reproduction in America at the end of 1878. Sullivan sailed for New York the same year to superintend the production of *Pinafore* under his leadership. He since composed in connection with W. S. Gilbert another comic opera, the *Pirates of Penzance*, which met with considerable success. The honorary degree of doctor of music was conferred upon him by the university of Cambridge in 1876. He was English delegate to the *commission des auditions musicales* of the Paris exhibition of 1878, when he was made chevalier of the legion of honor.

SULLIVAN, JAMES, LL.D., 1744—1808, b. Me.; king's attorney for York county. He sympathized with the patriotic party, however; was in 1775 a member of the provincial congress of Massachusetts from which Maine had not yet been separated, and was sent as a commissioner to Ticonderoga. In 1776 he became a justice of the superior court; was a member of the convention which formed a state constitution for Massachusetts in 1780, and was elected to congress in 1783. Removing to Boston, he represented that town in the legislature several years, served on the executive council, and was probate judge for Suffolk co., and was attorney-general of the state, 1790—1807. He served on the commission to fix the boundaries between the United States and Great Britain, and was governor of the state in 1807—8. He wrote a *History of the District of Maine* (1795), and a *History of Land Titles in Massachusetts* (1801).

SULLIVAN, JOHN, LL.D., 1740—95; b. Me.; in early life was a successful lawyer, but held his profession subservient to his zeal for American liberty. He was a member of the first continental congress; and through the darkest periods of the revolutionary war, he ranked among the ablest leaders of the American armies. In the siege of Boston he was next in command to gen. Lee. When in the battle of Long Island, in 1776, gen. Greene was disabled by sickness, Sullivan was selected to command his division of the

army. Serving afterward under the immediate supervision of Washington, Gen. Sullivan was distinguished for his discretion and valor in the battles of Trenton, Princeton, Brandywine, and Germantown. In 1778 Washington and count d'Estaing arranged for the French fleet to attack the British near Rhode Island, and Sullivan was sent with a large force to co-operate in besieging Newport. On the day appointed for the combined attack, a violent storm so shattered the French vessels that they withdrew from the contest. After defeating the English in one engagement, the American forces retired from Rhode Island. In 1779 Sullivan was sent with a large force into western New York to take vengeance upon the hordes of Indians and Tories who, besides other atrocities, had massacred the inhabitants of Wyoming and Cherry valley. The savages were dispersed, many were killed, and their villages destroyed. In 1780 Gen. Sullivan resigned his commission and returned to New Hampshire and to his profession of the law. After successfully filling many important civil and judicial offices, died at Durham, N. H.

SULLIVAN, JOHN LANGDON, 1777-1865, b. Maine; studied canal construction in England and on the continent. He was agent and engineer of the Middlesex canal, 1804-11. He was associate civil engineer of the U. S. board of internal improvements, 1824-25; and published reports on the feasibility of a canal through the Alleghenies. He afterward practiced medicine, adopting the homeopathic system. In 1814 he received a patent for the invention of the steam tow-boat, being given priority over Robert Fulton.

SULLIVAN, WILLIAM, LL.D., 1774-1839, b. Maine; graduated at Harvard, 1792, studied law, and for many years practiced in Suffolk co.; Mass. He was for a long period a member of the legislature, and is best known as the author of political, historical, and moral *Class Books*; *Familiar Letters on the Public Men of the Revolution* (1834); and *Historical Causes and Effects* (1838).

SULLIVAN'S ISLAND, a large island, 6 m. below Charleston, S. C., between the harbor and ocean, the site of fort Moultrie, now dismantled, and of the summer residences of the wealthy inhabitants. When fort Moultrie was evacuated by Maj. Anderson, Dec. 26, 1830, several batteries were erected on the shore of this island, bearing upon the channel and fort Sumter.

SULLIVANT, WILLIAM STARLING, LL.D., 1803-73; b. Franklinton, Ohio; graduate of Yale college, 1823; became a surveyor and resident of Columbus, and published catalogues and specimens of plants and mosses. He has made contributions to the bryology and hepaticology of North America; to Asa Gray's *Manual of Botany*, and numerous other works, besides contributing valuable papers to scientific journals. Associated with L. Lesquereux he published *Musci Boreali-Americani*, consisting of 350 species and varieties of dried mosses. He discovered a plant of the saxifrage family on which was founded the genus *Sullivantia*.

SULLY, a new co. of s. e. Dakota, bounded on the w. by the Missouri river, and drained by its branches; 1100 sq. miles. The surface is mostly rolling prairie; the soil bordering the Missouri river is very fertile. Co. seat, Fort Sully.

SULLY, MAXIMILIEN DE BETHUNE, Duke of, the celebrated minister of Henry IV. of France, was the second son of François, baron de Rosny, and was born at Rosny, near Mantes, in 1560. The Rosny family, an offshoot from the great house of Flanders, was never possessed of much wealth or influence, and had severely deteriorated in both respects during the early religious wars. Sully was at an early age committed to the care of Henry of Navarre, the head of the Huguenot party, which not only obtained for him an excellent education, but laid the foundation of a companionship which lasted, without intermission, till Henry's death. After narrowly escaping during the St. Bartholomew massacre, he accompanied his patron in his flight from court (1575), and during the civil war which followed, exerted himself to the utmost, by daring valor in the field and otherwise, to serve the master for whom he cherished the most absorbing devotion. After Henry's authority had been well established, Sully, who had for some years previous been his trusted adviser, became (1594) counselor of state and of finance. The financial affairs of the country were then in a frightful condition; from the chief of the department down to the very lowest country agent, the administration was an organized system of pillage, and but a small percentage of the taxes levied found its way into the imperial treasury. The baron de Rosny was the very man to remedy this state of matters: rude, obstinate, and haughty, but at the same time resolute, active, indefatigable, wholly devoted to his master's interests; and backed by the influence of Gabrielle d'Estrees, and by Henry's own clear-sighted convictions, he cared nothing for the clamor and hatred of the court, which had largely profited by the former state of chaos. Not content with regulating the affairs of the revenue from the seat of power, he made a tour through the chief provincial districts, armed with absolute authority, personally examined the accounts, dismissed or suspended delinquents, and largely replenished the treasury with the ill-gotten wealth which he compelled them to disgorge. By indomitable perseverance, he little by little brought the affairs of the country into an orderly state; although in the diminution of the expenditure his efforts were by no means so successful, as the king, his mistresses, and the other companions of his pleasures, combined to oppose all retrenchment as far as they were concerned. In 1596 the disposable revenue of the state was 7 to 9 millions; in 1609 it was no less than 20 millions, with a

surplus of 20 to 22 millions in the treasury, and the arsenals and fleet in a state of excellent equipment. Sully, however, was more than a mere financier; he had the supreme charge of various other branches of the administration, zealously promoted agriculture by diminishing the taxes of the peasantry, encouraging export trade, draining marshlands, and constructing numerous roads, bridges, and causeways. Sully was the servant of the king and government alone, and was of necessity disliked by the people for his severity, by the Catholics for his religion, and by the Protestants for his invariable refusals to sacrifice the smallest jot of his master's or the country's interest for their sake. Accordingly, with the death of Henry, his career of supremacy was at once ended, and he was forced to resign the superintendence of finance, Jan. 26, 1611, though he retained his other high offices, and was presented by Maria de Medicis with 300,000 livres as acknowledgment of his services. He had been created duke of Sully and peer of France in Feb., 1603. Sully wrote three treatises on war and police, which are lost, and two pieces of verse which are extant; but the work which will ever be connected with his name is the *Mémoires des sages et royaux Économies d'État de Henry le Grand*; a dull, wearisome, and disorderly collection of writings, but of priceless value to a historian of Henry IV.'s time. Sully printed the first two volumes of the *Mémoires* at his own château of Sully in 1634, the third and fourth were published at Paris in 1662, and the whole has been several times republished, as well as translated into English, German, and Russian. Sully died at Villebon, near Chartres (Eure-et-Loir), Dec. 22, 1641. Artists have generally represented Sully as older than Henry IV., while in reality he was seven years younger.

SULLY, THOMAS, 1782-1872, b. England; brought to this country by his parents. From 1798-1804 he resided in Charleston, S. C., studied art and produced some juvenile pieces. He then settled in Richmond, Va., and later in New York, in both places practicing the profession of a portrait painter with great success. In 1809 he removed to Philadelphia, where the rest of his life was spent, with exception of visits abroad, in one of which he painted an excellent portrait of queen Victoria. The Boston museum possesses his most ambitious work, "Washington Crossing the Delaware." Among his best portraits were those of Cooke the tragedian as Richard III., Fanny Kemble, Dr. Rush, Decatur, Jefferson, and Lafayette.

SULMONA, or **SOLMONA**, a city of southern Italy, province of Aquila, in Abruzzi. Pop. 71, 12,583. It is situated in a vast fertile plain, watered by two rivers, and bounded by hills. It is very well built, having one very wide street in the center of the city. There is a handsome town-hall, a cathedral, and a convent dedicated to St. Pietro Celestino, built with stones from the ancient *corfinium*. It has paper manufactories, dye-houses, and tan-yards. Sulmona was the birthplace of Ovid. In the 8th and 9th centuries, it was sacked by the Saracens, but was restored under the Normans, and has ever since been a flourishing and industrious city.

SULPHATES. See SULPHURIC ACID.

SULPHIDES, METALLIC, formerly known as *sulphurets*, are combinations of sulphur with a metal. Many of them occur native, and form highly valuable ores. They are all solid at ordinary temperatures, and, with the exception of those of potassium, sodium, calcium, strontium, barium, and magnesium, are insoluble in water; they are, moreover, conductors of electricity. Many of them, especially of those that occur native, exhibit very brilliant and characteristic colors. The same metal may have several sulphides, and in general there is a sulphide for each oxide. The sulphides are, however, sometimes the more numerous. Most of these compounds may be fused at a heat a little above redness, and if the air be excluded, the protosulphides (those containing one atom of sulphur and one atom of metal) remain unaffected; but many of the higher sulphides, such as the bisulphide of iron (FeS_2) and the bisulphide of tin (SnS_2) give off an atom of sulphur, and are reduced to protosulphides. If, however, there is a free admission of air or of oxygen gas to the heated sulphides, they are all decomposed, the sulphur becoming oxidized, and passing off as sulphurous acid (SO_2), while the metal usually remains in combination with oxygen. When heated before the blowpipe, most of the sulphides evolve an odor of sulphurous acid, and very small quantities of soluble sulphides may be detected in neutral or alkaline solutions by the addition of a solution of nitroprusside of sodium ($\text{Na}_2\text{Fe}_3\text{Cy}_6\text{NO}_2 + 4\text{Aq}$), when a magnificent purple color, which, however, is not permanent, is evolved. It has very recently been discovered by Mr. Barrett, and announced in his paper, "On some Physical Effects produced by the contact of a Hydrogen Flame with various Bodies," in the *Philosophical Magazine* for Nov., 1865, that the sudden appearance of a blue color when the hydrogen flame is brought in contact with a body containing sulphur, is a most delicate test for the presence of this element, detecting it even when the nitro-prusside of sodium test fails. By this test Mr. Barrett detected $\frac{1}{100,000}$ of a grain of sulphur.

The sulphides are prepared in various ways, of which it is sufficient to notice the most important. (1.) The protosulphides of the metals of the alkalies and alkaline earths may be obtained by decomposing their sulphates by igniting them in closed vessels with charcoal, the oxygen being removed in the form of carbonic oxide. (2.) Many of the metals, when heated with sulphur, combine directly with it; sulphide of iron, for example, is usually prepared in this manner. (3.) Hydrated sulphide of tin, titanium, molybdenum,

tungsten, vanadium, arsenic, antimony, bismuth, copper, lead, mercury, silver, gold, and platinum with its allied metals may be obtained by passing a stream of sulphuretted hydrogen through neutral or acid solutions of their salts, when they are precipitated in an insoluble form; and the hydrated sulphides of zinc, iron, manganese, cobalt, and nickel may be prepared by double decomposition, by mixing a solution of the salt of the metal with a solution of a sulphide of one of the metals of the alkalies, as, for example, sulphide of potassium: thus, sulphate of zinc, if mixed with sulphide of potassium, yields sulphate of potash, which remains in solution, and sulphide of manganese, which falls as an insoluble precipitate. "In many cases," says prof. Miller, "the atoms of these hydrated sulphides are characteristic of the metal; for example, the hydrated sulphide of zinc is white; that of manganese, flesh red; those of cadmium, arsenic, and persulphide of tin are yellow; that of tersulphide of antimony is orange red; and that of hydrated protosulphide of tin is chocolate brown. The sulphides of molybdenum, rhodium, iridium, and osmium are brown, each with its peculiar shade, while in a large number of instances—including the sulphides of iron, cobalt, nickel, uranium, vanadium, bismuth, copper, lead, silver, mercury, gold, platinum, and palladium—the precipitated sulphides are of a black, more or less pure."—*Inorganic Chemistry*, 2d ed. 1860, p. 322. A recollection of the colors of these precipitates will save the young chemist a large amount of labor in testing for the presence of the metals.

SULPHOCYAN' OGEN AND THE SULPHOCYANIDES. The former of these terms is given to a monobasic radical, C_2NS_2 , or CyS_2 , which has never yet been isolated, but which forms an acid compound, known as hydrosulphocyanic acid (H, C_2NS_2), with hydrogen, and yields numerous metallic salts. These salts, known as sulphocyanides, may be represented by the general formula, M, CyS_2 , where M represents any metal. The sulphocyanides of potassium, sodium, and ammonium are crystallizable and soluble in water; those of the heavy metals are comparatively insoluble. These salts do not possess the poisonous character of the cyanides. *Sulphocyanide of potassium* (K, CyS_2) is anhydrous, but very deliquescent, and occurs in long streaked colorless prisms, somewhat resembling niter both in appearance and taste; it is extremely soluble in water, and fuses on the application of a gentle heat. The *sulphocyanide of mercury* is a white powder which possesses the property of swelling or growing in size to an almost incredible degree when moderately heated, so as to decompose it into a mixture of mellon ($C_{15}N_{13}$), with a little sulphide of mercury. The resulting mass often assumes a most fantastic shape, and is sufficiently coherent to retain its form: it is of a yellow color externally, but black within. It is this sulphocyanide which is the ingredient of the well-known toy known as "Pharaoh's serpents." Each serpent consists of a little cone of tinfoil, resembling a pastille in shape, and filled with the above-named compound. On lighting the cone at the apex, there begins to issue from it a thick serpent-like coil, which continues twisting and increasing in length to an extraordinary degree, the serpent-like shape resulting from the salt being burned in the tinfoil cone. The compound is readily obtained by precipitating a strong solution of permanganate of mercury with sulphocyanide of ammonium, which is most cheaply prepared by Mr. Wood's method from bisulphide of carbon.

SULPHOVINIC OR SULPHETHYLIC ACID (HO, C_4HO, S_2O_6) is formed by mixing alcohol with an equal bulk of oil of vitriol. Great heat is evolved, and the two bodies enter partially into combination; this new compound acid possessing only half the saturating capacity of sulphuric acid. In connection with the theory of the formation of ether from alcohol and sulphuric acid, it may be observed that this sulphovinic acid is developed as an intermediate product, if the temperature be raised to 212° , but not otherwise. This is one of the class of acids to which the term *vinic acids* is applied.

SULPHUR (symb. S, eq. 16—new system, 32—sp. gr. of rolled sulphur, 1.98 [see ATOMIC WEIGHTS], and of amorphous sulphur, 1.957; sp. gr. of vapor, 6.617 at 824° , and 2.2 at 1900° , atmospheric air being the unit of comparison for the vapor) is one of the most important of the non-metallic elements. At an ordinary temperature, it exists as a solid, brittle, tasteless, and inodorous body, of a characteristic yellow color, and insoluble in water. A piece of solid sulphur, heated to a temperature of 239° , fuses into a thin yellow liquid; while in closed vessels, it may, by a further heat, be distilled, the boiling-point being about 824° , and at this temperature it yields a deep yellow vapor, of sp. gr. 6.617. When the sulphur-vapor comes in contact with cold air, it condenses in the form of a fine yellow powder, known as *flowers of sulphur*. If fused sulphur be rapidly cooled, it solidifies into a compact mass, of a granular crystalline texture, and if, in its liquid state, it be allowed to run into cylindrical wooden molds, we obtain it in the ordinary form of roll-sulphur, or common brimstone; if, on the other hand, it be allowed to cool slowly, it crystallizes in long, glistening, deep, yellow, oblique prisms, with a rhombic base, which, however, soon lose their most characteristic properties. As native sulphur is frequently met with in yellow crystals, whose form is derived from the octahedron with a rhombic base, it is obviously a dimorphous substance. It has been already stated that sulphur fuses at 239° ; from that temperature up to 280° , it forms a yellow, transparent, limpid liquid; as the heat increases, the color becomes brown, and almost black, and the liquid becomes viscid, these changes being very distinctly seen at 350° . If the external application of heat be steadily continued, it will be found that for

a while the temperature remains constant, but it afterward rises, and at nearly 500° , the sulphur again liquefies, although less completely than when first melted. If it be now suddenly cooled by pouring it, in a slender stream, into cold water, we obtain a spongy, tenacious, and plastic mass, which may be drawn out into elastic threads, whose color, after they have cooled, varies from an amber to a deep brown color, according to the heat that has been employed. After some hours the ductile sulphur loses its characteristic properties, increases in density, and returns to the brittle form; or, if it be heated to 212° , it suddenly returns to the brittle condition; the temperature rising to 239° during the change. Hence, sulphur may be obtained in three (if not in more) allotropic states, which are distinguished by the symbols S_{α} , S_{β} , S_{γ} . The first variety, S_{α} , is the native octahedral crystal of sulphur; it may be obtained artificially by dissolving sulphur in bisulphide of carbon, or chloride of sulphur, and submitting the solution to spontaneous evaporation. These crystals are semi-transparent, of an amber-yellow color, and undergo no change on exposure to the air. The second variety, S_{β} , is the oblique prismatic crystal already described as being formed when fused sulphur cools slowly. The best method of obtaining these crystals is to melt a few pounds of sulphur, and allow it to solidify on the surface. On perforating the external crust with a hot wire, and pouring out the sulphur that remains liquid, the interior of the cavity is found to be traversed in all directions by these crystals, occurring as transparent brownish needles, having a specific gravity considerably less even than that of roll sulphur. On exposure to the air they soon lose their coherence, and form an opaque and crumbling mass, consisting of minute rhombic octahedra. This conversion of the prismatic into the octahedral form takes place immediately if the prisms are immersed in bisulphide of carbon. The third variety, S_{γ} , is the plastic amorphous sulphur, which has been sufficiently described. If sulphur be frequently heated to 600° , and suddenly cooled, a black variety of this element is produced; and a red variety has been obtained, but the redness is now supposed to be due to the presence of a trace of some fatty body.

Sulphur is a bad conductor of heat, and the mere heat of a warm hand often causes it to crackle, and even to fall to pieces, from the unequal expansion. It is an insulator of electricity, and becomes negatively electric by friction. It is slightly soluble in alcohol, ether, and the fatty oils; its best solvents being the bisulphide of carbon and chloride of sulphur. When it is heated in the air, it takes fire at about 470° , burning with a blue flame, and becoming converted into sulphurous acid, whose pungent suffocating fumes are characteristic of sulphur. This element is second only to oxygen in its powerful affinity for other elements, with most of which it unites, and often in several proportions. With most of the metals it combines very readily, and in some cases, with a development of light and heat; thus, silver and copper burn in sulphur-vapor just as iron-wire or zinc-foil burns in oxygen. In consequence of its power, with the aid of heat, of forming sulphurous acid with the oxygen of the air, and thus rendering the latter incapable of supporting combustion, burning sulphur may be usefully employed for the extinguishing of fire—as, for example, in chimneys.

Sulphur occurs very widely distributed in the mineral kingdom, partly free and partly combined with other elements. The free sulphur is either found pure in regularly formed crystals, or intimately mixed with earthy matters. The principal sources of crystalline sulphur are Urbino in Italy, Girgenti in Sicily, and Radoboy in Croatia; while the earthy sulphur is mainly derived from Italy, Moravia, and Poland. Iceland is rich in both varieties, but the mineral wealth of that island remains almost unworked. At present, by far the greatest quantity of the sulphur employed in Europe comes from Sicily; and, as a general rule, it is abundant in volcanic districts. In the form of sulphide, sulphur occurs abundantly in combination with iron, copper (iron and copper pyrites), lead (galena), zinc (blende), etc., the bisulphide of iron (or iron pyrites) furnishing most of the sulphur that is employed in the manufacture of sulphuric acid. Sulphur is still more extensively distributed in the form of sulphates, the sulphates of lime, magnesia, baryta, etc., being abundant natural productions. In the vegetable kingdom, sulphur is a constituent (although only to a small amount) of the albuminous bodies which are so widely diffused in plants; and of certain volatile irritant oils, as those of mustard, garlic, asafetida, etc.; and, moreover, the vegetable juices contain it in the form of certain sulphates. In the animal kingdom, it is not only a constituent of the albuminous, fibrinous, and gelatinous tissues, but of the hair, saliva, bile, urine, etc. The two animal substances in which it is most abundant are cystin (q.v.), an occasional constituent of urinary calculi, and taurine (q.v.), a constituent of the bile, in both of which it forms about a quarter of the entire weight.

It would be out of place in this article to enter into details regarding the *extraction* or *preparation* of sulphur. It is sufficient to state that the grosser impurities are removed by crude processes of fusion and distillation at or near the place from whence it is obtained. That which is imported into Britain undergoes further purification. What is called *refined sulphur* is that purified by distillation in a large cast-iron still, and condensed in a receiver kept cool. When the vaporized sulphur is condensed in a large chamber, it is obtained in the form of *sublimed sulphur*, or *flowers of sulphur*; but as the walls get hot, it melts and collects on the floor, and is run into cylindrical wooden molds, from which, when cool, it is taken out as *roll* or *stick sulphur*. The residue left in the retort is a mixture of sulphur with various impurities. Under the names of *black*

sulphur, or *sulphur vivum* (commonly inquired for at the chemist's under the title of *sulphur of ivy*), it is used in veterinary medicine, and for the purpose of dressing moldy hops. Sulphur is thrown down from certain of its compounds (as from a strong solution of a polysulphide of calcium, sodium, or potassium) by dilute hydrochloric acid; it falls as a grayish-white, very fine, light powder, known in the *Materia Medica* as *milk of sulphur*, or *precipitated sulphur*. For the method of obtaining sulphur from iron pyrites, we must refer the reader to Miller's *Inorganic Chemistry*, 2d ed. p.154. The proceeding is usually conducted on a large scale, 2,000 tons of pyrites being roasted at once, the roasting extended over five or six months, and the final result being about 20 tons of sulphur. The most common impurities met with in ordinary commercial sulphur are selenium and realgar (bisulphide of arsenic). Flowers of sulphur frequently exhibit a slight acid reaction, in consequence of a little sulphurous acid clinging to them. By rinsing them with water, this impurity is at once removed.

Sulphur is extensively employed in the arts and manufactures; as in the manufacture of matches, gunpowder, etc. When converted into sulphurous acid, it is employed as a powerful bleaching agent, and also for the destruction of insects, fungi, etc.; but its chief consumption is in the manufacture of sulphuric acid.

The compounds of sulphur and oxygen are no less than seven in number, all of which present the characters of acids. These acids have the following composition:

		Sulphur.	Oxygen.
Sulphurous acid.....	SO ₂	16	16
Sulphuric acid.....	SO ₃	16	: 24
Hyposulphurous acid.....	S ₂ O ₂	32	: 16
Hyposulphuric acid.....	S ₂ O ₃	32	: 40
Trithionic acid.....	S ₃ O ₃	48	: 40
Tetrathionic acid.....	S ₄ O ₃	64	: 40
Pentathionic acid.....	S ₅ O ₃	80	: 40

The last five of these acids have never been obtained in the anhydrous form. We shall only notice the most important members of this group, viz., the first three of them, and of these, the second, *sulphuric acid*, is so extremely important, that it is discussed in a special article. (The last three derive the essential portion of their name from the Greek word *thion*, sulphur.)

SULPHUROUS ACID or SULPHUROUS ANHYDRIDE (SO₂), occurs under the ordinary relations of temperature and pressure as a colorless gas, possessing the suffocating odor of burning sulphur. In its concentrated form it is quite irrespirable, and in a diluted state it excites cough, and produces the symptoms of an ordinary catarrh. It is not only incapable of burning, but it rapidly extinguishes the flame of burning bodies. It is very freely soluble in cold water, which at 32° takes up nearly 69 times its volume of the gas, while at 75° it only takes up 32 volumes; the solution known as *aqueous sulphurous acid* having at first the same smell and taste as the gas, but soon absorbing oxygen from the air, and becoming converted into sulphuric acid. By the action of cold, sulphurous acid may be condensed to a colorless transparent limpid liquid, which freezes at -105°, forming a transparent crystalline solid. The specific gravity of the gas is 2.247 (atmospheric air being the unit), and that of the liquid is 1.49 (water being the unit), the solid being considerably heavier. Although dry sulphurous acid gas and dry oxygen, when mixed, exert no action on one another, there are many conditions under which sulphurous acid rapidly absorbs oxygen, and is converted into sulphuric acid. It has been mentioned that this takes place if the gas be dissolved in water; a similar action takes place under the influence of hydrated nitric acid, iodic acid, and certain metallic oxides. For example, oxide of lead, when immersed in the gas, burns, and is converted into white sulphate of zinc (PbO₂ + SO₂ = PbO₂SO₃). Hence, sulphurous acid is a powerful reducing or deoxidizing agent. This gas is a common and abundant product of volcanic action, and is occasionally met with in solution in the springs in volcanic regions. It may be prepared artificially by simply burning sulphur in the air or in oxygen gas, or by heating in a flask 4 parts of flowers of sulphur mixed with 5 parts of powdered black manganese, sulphurous acid and sulphide of manganese being the products, as shown by the equation 2S + MnO₂ = SO₂ + MnS. In consequence of its solubility in water, this gas should be collected over mercury. In addition to the uses of sulphurous acid as a bleaching agent, it is valuable both as a disinfectant agent and as a powerful antiseptic; its latter property has been applied to the preservation of meat, which, after exposure to this acid, will keep fresh for years, if it be inclosed in metallic canisters filled with nitrogen, to which a little bin oxide of nitrogen has been added, to remove any trace of oxygen. But by far its most important use is, as a first stage in the manufacture of sulphuric acid. In combination with bases, this acid forms the *sulphites*—a class of salts which, excepting the sulphite of soda, are of little practical importance, except for their power, when moist, of extracting oxygen, and thus acting as reducing agents. For example, the salts of the sesquioxide of iron are reduced by them to salts of the protoxide.

HYPOSULPHUROUS ACID (S₂O₂) as yet is only known in a state of combination with bases; for on attempting to separate the acid from the base, the former becomes decom-

posed into sulphur and sulphurous acid. The most important of its salts is the *hyposulphite of soda* ($\text{NaO}, \text{S}_2\text{O}_2 + 5\text{Aq}$), whose mode of preparation and characters are described in the article **SODIUM**. This and other soluble hyposulphites may be easily recognized by the facility with which they dissolve the haloid salts of silver, forming a solution of an extremely sweet taste, and containing a double hyposulphite of silver and soda, with an admixture of chloride, iodide, or bromide of sodium. It is this power of dissolving those salts of silver which are insoluble in water, that renders the hyposulphite of soda so important an agent in photography. The only other salt of this acid which we shall notice is the *hyposulphite of gold and soda* [$\text{AuO}, \text{S}_2\text{O}_2.3 (\text{NaO}, \text{S}_2\text{O}_2) + 4 \text{Aq}$] which may be prepared by mixing concentrated solutions of 1 part of chloride of gold and 3 parts of hyposulphite of soda, and adding alcohol, when the required salt is precipitated. It is used for gilding the daguerreotype plate, and for coloring the positive proof obtained in photographic printing.

With hydrogen, sulphur forms two compounds, viz., *sulphureted hydrogen*, or *hydrosulphuric acid* (q.v.), and *persulphide of hydrogen*, an oily liquid, having the smell and taste of sulphureted hydrogen, and in many of its properties having an analogy to binoxide of hydrogen. Sulphur combines with carbon to form a *bisulphide of carbon* (CS_2), a very volatile colorless liquid, of a high refractive power, of an acid and pungent taste, and a very disagreeable odor. It is heavier than water, in which it is insoluble, but dissolves freely in alcohol and ether, and is the best solvent for sulphur and phosphorus. Bisulphide of carbon does not occur as a natural product, but may be obtained by heating fragments of charcoal to bright redness in a porcelain tube, and passing sulphur vapor along it. Its vapor, when freely inhaled, exerts a similar anæsthetic action with those of chloroform and ether. Workmen in caoutchouc or other manufactures in which bisulphide of carbon is used as a solvent, suffer very much from prolonged exposure to its vapor, which produces headache, loss of appetite, impairment of vision and hearing, and causes general derangement of health by its deleterious action on the nervous system. Sulphur combines with chlorine in several proportions, the most important of these compounds being *subchloride of sulphur* (S_2Cl) and the *chloride of sulphur* (SCl). Both of them are liquids, and are formed by the direct action of the combining elements. The subchloride is a yellow volatile liquid with a penetrating and disagreeable odor. When dropped in water, it sinks to the bottom (its spec. grav. being about 1.687), and is slowly decomposed into hydrochloric and various sulphur acids, and free sulphur. It is capable of dissolving about 67 per cent of sulphur at an ordinary temperature, and, like bisulphide of carbon, is extensively employed in vulcanizing india-rubber. The chloride of sulphur is formed by saturating the subchloride with chlorine. It is a deep-red liquid, resembling the previous compound in most of its properties. It is decomposed by the sun's rays into the subchloride and free chlorine.

With regard to the history of sulphur and its compounds, it may be observed that sulphur seems to have been known from the earliest times, and that sulphuric acid was most probably known to the Arabians. The manufacture of English sulphuric acid dates, however, only from the 18th century. Sulphurous acid was first investigated by Stahl, Scheele, and Priestley; hyposulphuric acid was discovered by Welter and Gay-Lussac; hyposulphurous acid, by Gay-Lussac and Herschel; trithionic acid, by Langlois; tetrathionic acid, by Fordos and Gelis; and pentathionic acid, by Wackenroder. Scheele was the first who accurately studied hydrosulphuric acid, or sulphureted hydrogen.

Sulphur is used to a considerable extent and for very different purposes in medicine. It is given internally either as sublimed sulphur (flowers of sulphur) or as precipitated sulphur (milk of sulphur), in somewhat large doses, as a mild cathartic—its purgative effects being due to its stimulating the muscular coat of the intestines. In consequence of its being both gentle and sure in its action, it is the best purgative to employ in cases of piles, or in stricture or other painful affections of the rectum. The only objection to its use is that, from its becoming partly converted in the system into sulphureted hydrogen, the evacuations, and even the insensible perspiration, often become abominably fetid and continue so for some time after the primary operation of the medicine. As a purgative, the dose is about two drams, made into an electuary with treacle or honey. It is, however, generally combined with jalap and cream of tartar.

The *confection of sulphur* of the Pharmacopœia is composed of sulphur, cream of tartar, and syrup of orange-peel rubbed together—the dose being from half an ounce to an ounce, or from one to two tablespoonfuls. In small doses, sulphur is of great value in cases of atonic gout and chronic rheumatism. An electuary known as the *Chelsea pensioner*, consisting of two ounces of sublimed sulphur, one ounce of powdered rhubarb, half an ounce of resin of guaiacum, one ounce of cream of tartar, half an ounce of ginger, and two drams of powdered nutmegs, with as much treacle as is necessary, in doses of one or two teaspoonfuls night and morning, is a combination of great value in these cases. It originally gained its reputation by curing Lord Amherst of rheumatism, and is still a favorite remedy at Chelsea hospital. Dr. Nelligan states that steaming the lower bowel, by sitting over the vapor of warm water upon which a tablespoonful of flowers of sulphur had been sprinkled, constitutes a most valuable remedy in what is popularly known as a 'fit of the piles.' The external use of sulphur in the form of

ointment has been already noticed in the article IRON. It is also used externally in many other cutaneous disorders, particularly in lepra and psoriasis; and in chronic cases, its application in the form of vapor is often of great service.

SULPHURIC ACID, or, more correctly, hydrated sulphuric acid (SO_3, HO), is the chemical name of the liquid commercially and popularly known as *oil of vitriol*.* It is a dense, colorless, oily liquid, without smell, of a spec. grav. of 1.846 at a temperature of 60° , and of an intensely acid taste and reaction. It has a powerful caustic action, and chars and destroys organic matters from its strong affinity for water; and in consequence of this destructive property, it must always be handled with the greatest caution. So powerful is this affinity, that if the acid be exposed for a few days to the air in a shallow dish, so as to present a large surface, it often doubles its weight by absorbing aqueous vapor from the air; and in consequence of its possessing this property it is extensively used in laboratory operations as a desiccating agent. It mixes completely with water in all proportions, and as great heat is given out at the moment of mixture, the dilution should be performed by very gradually adding the acid to the water. When cold the mixture occupies less bulk than the two components previously occupied. This acid freezes at a temperature of 15° , and boils at 620° (or according to Marignac, at 640°), and just above the boiling-point it assumes the form of a vapor, with a spec. grav. of 2.15. Oil of vitriol, or the protohydrate, is not the only hydrate of sulphuric acid. Three others are known to exist. When the fuming oil of vitriol of Nordhausen is exposed to a low temperature, a white crystalline substance separates, which is a hydrate, containing half as much water as the common liquid acid. Its formula is $2\text{SO}_3, \text{HO}$, or $(\text{SO}_3)_2, \text{HO}$. Its fusing point is 95° . Then, again, a mixture of 49 parts of strong liquid acid and 9 parts of water ($\text{SO}_3, 2\text{HO}$) freezes at 47° , and crystallizes into splendid rhombic prisms, from which property it is often termed *glacial sulphuric acid*. It boils at 435° , and its spec. grav. is 1.780. Lastly, when a very dilute acid is concentrated by evaporation *in vacuo*, at 212° , till it ceases to lose weight, there will be a resulting compound, consisting of 40 parts of the real acid, and 27 of water, and represented by the formula, $\text{SO}_3, 3\text{HO}$. It boils at 348° , and its spec. grav. is 1.602. There are thus no less than four hydrates of sulphuric acid—viz.: (1) the dihydrate, $2\text{SO}_3, \text{HO}$; (2) the ordinary protohydrate, SO_3, HO ; (3) the bihydrate, $\text{SO}_3, 2\text{HO}$; and (4) the trihydrate, $\text{SO}_3, 3\text{HO}$. The compound formerly known as *anhydrous sulphuric acid* possesses none of the characteristic properties of an acid. See SULPHURIC ANHYDRIDE; also CHEMISTRY.

Sulphuric acid in its free state is a very rare natural product; although, in combination with bases, it is common in the animal and vegetable, and abundant in the inorganic kingdom. The only cases in which it is known to occur free are certain American rivers, especially the rio Vinagre, and some lakes in Tennessee and in Java; and it has been found to be a normal constituent of the saliva of *dolium galia*, a species of snail found in Sicily. In all these cases the acid is, of course, in an extremely diluted form. In plants it exists in the juices, and in animals in the blood and its derivative chiefly in the form of sulphates of the alkalies; while in the mineral kingdom it occurs as gypsum (sulphate of lime), heavy spar (sulphate of baryta), celestine (sulphate of strontia), etc.

Sulphuric acid may be prepared on a small scale by boiling sulphur in *aqua regia*, or in nitric acid, the sulphur becoming gradually oxidized into sulphuric acid. As a general rule, however, the commercial acid is employed even for laboratory experiments. See below.

In order to obtain the acid in a pure form, suitable for medical use or medico-legal analyses, it must be redistilled with sulphate of ammonia in a retort containing a few slips of platinum foil, the first and last portions being rejected. The distillation is attended with violent concussions, partly owing to the high specific gravity of the acid, and partly owing to its high boiling-point, and this convulsive action is moderated mechanically by the platinum slips. Sulphuric acid thus prepared according to the direction of the British pharmacopœia may be regarded as perfectly pure, presuming arsenic is not present. Strong sulphuric acid has comparatively little action on the metals except at a high temperature, when it dissolves them, and, at the same time, undergoes partial decomposition; the metal being oxidized by a portion of the acid which becomes decomposed into oxygen and sulphurous acid, and then uniting with a portion of undecomposed acid to form a sulphate. Silver, copper, mercury, arsenic, antimony, bismuth, tin, lead, and tellurium are thus acted on. Gold, platinum, rhodium, and iridium are not affected by the acid even at a boiling temperature. The more oxidizable metals, such as zinc, iron, nickel, and manganese, are readily soluble in the dilute acid, water being decomposed, and hydrogen liberated, while the oxygen of the water unites with the metal; and the metallic oxide, at the moment of its formation, combines with the sulphuric acid to form a sulphate.

The *sulphates*—or salts formed by the combination of sulphuric acid with a base—are generally composed, as in the case of green vitriol ($\text{FeO}, \text{SO}_3 + 7\text{Aq}$), of 1 equivalent of acid and 1 of metallic oxide, with or without water of crystallization. With the alkalies this acid also forms acid salts, as bisulphate of potash, and in a few cases—copper,

* It received this name from having been first produced by the distillation of green vitriol (sulphate of iron); Basil Valentine being usually credited with the discovery. See ALCHEMY.

for example—it forms basic salts. The insoluble sulphates, such as that of baryta, may be obtained by precipitating a soluble salt of the base by a soluble sulphate; thus, nitrate of baryta and sulphate of soda yield an insoluble sulphate of baryta and nitrate of soda, which remains in solution. The soluble sulphates may be prepared by dissolving the oxide or carbonate in dilute sulphuric acid, in those cases in which the metal itself is not readily attacked by the acid. Sulphuric acid and the soluble sulphates are easily detected by their yielding, with a solution of a baryta salt, a white precipitate of sulphate of baryta insoluble in acids.

This acid is employed in the arts and manufactures for a large number of purposes. Its use as a desiccating agent for laboratory purposes has been already noticed, and its application to the development of oxygen gas has been described in the article on that element. But its greatest consumption, doubtless, is in the preparation of the *salt-cake*, which is used in the manufacture of carbonate of soda (q.v.).

In medicine a *dilute sulphuric acid*, formed by gradually mixing three fluid ounces of the strong purified acid with thirty-five fluid ounces of water, or *aromatic sulphuric acid* (known also as *elixir of vitriol*), prepared by mixing three ounces of sulphuric acid with a quart of rectified spirit, adding cinnamon and ginger, digesting for a week, and filtering, are almost always employed. In doses of from ten to thirty minims, properly diluted, these preparations exert a strong astringent power, and are serviceable in all forms of passive hemorrhages, and in checking inordinate discharges when they arise from debility. In ordinary diarrhœa, and even in the premonitory diarrhœa of cholera, dilute sulphuric acid is of great use. In painter's colic it is given in order to convert any lead that is absorbed into an insoluble sulphate, which is inert. Sulphuric acid lemonade is also used as a prophylactic against the disease. As this acid exerts a deleterious action on the teeth, it should be directed to suck it through a quill. In some cases it is prescribed not so much for its specific as for its solvent power; with this object it is usually prescribed with quinia. The strong acid is used in surgery as a caustic. In cases of *poisoning* with this acid the most prominent features are, burning pain extending from the mouth to the stomach, intense pain in the bowels, vomiting, great prostration, coldness of the surface, and fetor of the breath. The mucous membrane of the parts injured by the acid is at first converted into a white slough, which soon becomes black, and the patient usually dies from exhaustion within twenty-four hours. The best antidotes are the alkaline bicarbonates, or carbonate of magnesia. If the primary symptoms be conquered the patient often dies subsequently from stricture of the œsophagus.

Sulphuric Acid Manufacture.—There are two distinct processes by which sulphuric acid is at present prepared on a large scale—viz., by the distillation of green sulphate of iron—the original process of Valentine; and by the oxidation of sulphurous acid through the agency of nitrous acid and hyponitric acid. The first process is chiefly employed at Nordhansen, in Prussia, and is thus described by Fownes: "The sulphate of iron, derived from the oxidation of iron pyrites, is deprived by heat of the greater part of its water of crystallization, and subjected to a high heat in earthen retorts, to which receivers are added as soon as the acid begins to distill over. A part gets decomposed by the very high temperature; the remainder is driven off in vapor, which is condensed by the cold vessel containing a very small quantity of water or common sulphuric acid. The product is a brown oily liquid of about 1.9 specific gravity, fuming in the air, and very corrosive. It is chiefly used for the purpose of dissolving indigo."

The second method is that universally followed in Great Britain, the germs of which were likewise discovered by Valentine. He observed that when the fumes of burning sulphur were collected under a bell jar, slightly moistened with water, a small quantity of liquid was deposited. This liquid, which was simply sulphuric acid, on being concentrated from its solution by boiling, was long sold as oil of sulphur *per campanum* at prices as high as 2s. 6d. per ounce.

About the year 1740, the French chemists Lefevre and Lemery suggested that, by the use of niter along with the sulphur, the operation might be conducted in close vessels, and a much greater quantity of acid might be produced. This idea was acted on in England by a Dr. Ward, who established works at Twickenham and Richmond, conducting his manufacture by burning the mixed sulphur and niter in large stoppered glass receivers, into each of which a small quantity of water was first introduced. The substitution, by Dr. Roebuck of Birmingham, of lead chambers in place of glass vessels, may be regarded as essentially the establishment of the process of manufacture followed at the present day. Dr. Roebuck established his first works at Prestonpans in 1749.

The first stage in the manufacture of sulphuric acid is the preparation of sulphurous acid by the burning of sulphur or of iron pyrites. Previous to the year 1833, Sicilian sulphur was almost exclusively used in the manufacture, but in that year the very ill-advised establishment of a monopoly of the sulphur trade by the Sicilian government, and its consequent increase in price, diverted the minds of manufacturers to the employment of iron pyrites (sulphuret of iron), the use of which, as a source of sulphurous acid, was already not unknown. The monopoly was quickly abolished, on the representations of the English government, but not until it was demonstrated that the world was independent of Sicily both for sulphuric acid and sulphur. Iron pyrites is now much more used than sulphur, and the only hindrance to its universal adoption

is the presence of foreign matter in the pyrites, the most deleterious being arsenical compounds; and it has hitherto been found impracticable to free the sulphuric acid wholly from the arsenious acid which consequently accompanies it. This renders the acid prepared from pyrites inapplicable for many purposes.

When sulphur is the material used for producing the sulphurous acid, it is burned in an oven or "burner" (A) of brick-work, having a sole or bottom of iron, termed the "burner-plate." Under this a small fire is at first lighted, which is allowed to go out after the sulphur has ignited. A little above the sulphur, a small pot, called the niter pot, *n*, is either placed on a stand or hung from the roof, filled with a quantity of either nitrate of soda or nitrate of potash, with sulphuric acid sufficient for its decomposition—8 or 10 lbs. of the niter, with 5 or 6 lbs. of sulphuric acid, being allowed for every cwt. of sulphur. The decomposition of the niter by the action of heated sulphuric acid furnishes nitric acid fumes, which go over into the chamber along with the sulphurous acid. The sulphurous readily abstracts from the nitric acid the additional equivalent of oxygen required for its conversion into sulphuric acid, reducing the nitrous compound from nitric acid, NO_3 , to nitrous oxide, NO_2 ; the reaction being thus: $3\text{SO}_2 + \text{NO}_3 = 3\text{SO}_3 + \text{NO}_2$. Nitrous oxide in its turn quickly converts itself into nitrous acid, NO_3 , by the abstraction of two additional equivalents of oxygen from the air that is constantly entering the chamber through the burners. Again, in the presence of moisture, which is supplied by a jet of steam from the boiler C, sulphurous acid readily deprives the nitrous acid of two equivalents of oxygen, and thus forms two more volumes of sulphuric acid, and again liberates nitrous oxide; which is ready once more to seize upon the oxygen of the air, and would continue so acting and reacting *ad infinitum*.

Manufacture of Sulphuric Acid:

A, sulphur-burner, or furnace; B, lead chamber, shown in section at B'; C, steam boiler; D, leaden pan; E, coke tower; S, steam-pipe; *n*, niter pot.

turn, were it not carried forward and out by the chimney provided for the escape of the freed nitrogen.

The chamber is an immense box or room of lead, bound together with a strong framework of timber, and generally raised on arches several feet above the ground. Chambers vary in size from 60 to 140 ft. in length, and from 20 to 40 ft. in width and height. Curtains of lead proceeding alternately from the bottom to near the top, and *vice versa*, are very frequently used; they serve to retard the progress of the gases, and thus insure the transformations desired. The floor of the chamber is covered with water, into which the sulphuric acid falls as it is formed; and when this solution attains a certain strength, it is tapped off for concentration. When the gases reach the chimney, on account of the reactions of the nitrous compounds already explained, a large amount of nitrous acid would not only be wasted, but would also be deleterious to the neighborhood, were steps for its recovery not adopted. This recovery is usually effected by means of a tower filled with coke, E, down which a constant stream of strong sulphuric acid trickles, the acid absorbing the nitrous fumes in their way upward. Instead of a single chamber, curtained off or not as the case may be, sometimes three or five distinct chambers, connected by pipes, are employed, those communicating directly with the burners being termed working chambers, and the others receiving chambers, the last either acting as or communicating with a condenser or chimney. In France and Germany, the apparatus employed is generally of a more complicated nature, but in principle the operations are identical.

When iron pyrites is used as the source of sulphurous acid, a furnace somewhat on the principle of the ordinary lime-kiln is required. The pyrites is broken into pieces like nuts, washed, and spread in layers on plates heated to redness, and frequently stirred; or a quantity of coke is introduced with the first charge; and the heat evolved by the burning sulphur is thereafter sufficient fuel for the fresh charges. The exhausted ore is frequently sufficiently rich in copper for its extraction; indeed, when there is not

more than $2\frac{1}{2}$ per cent of that metal present in pyrites, it is now recovered, and this has led to the establishment of copper smelting works in connection with great chemical works near Newcastle and Manchester. The use of pyrites necessitates a chamber of comparatively larger size for the production of a given amount than is required when sulphur is used. The increased labor, with the greater quantity of niter washed, and other circumstances, tend to make the cost of acid from both sources nearly equal.

In consequence of strong sulphuric acid absorbing both sulphurous acid and nitrous acid, the acid requires to be drained off from the chamber while the solution is comparatively weak, at which strength, viz., of a specific gravity of about 1.4, it is used for some purposes in the arts, under the name of "chamber acid." This is concentrated by evaporating, in lead pans, D, till it reaches the specific gravity of 1.6, then boiling in a platinum retort, on which strong acid does not act, even at high heat, or in large flint-glass retorts. Platinum retorts are extremely expensive; one to hold 30 gallons costing nearly £900. Large glass retorts which were used before the introduction of the platinum retorts, are again coming into favor with manufacturers. The only objection to their use is the great expense arising from frequent breakages, and consequent loss of both acid and retort.

The manufacture of sulphuric acid is a very extensive industry; immense quantities of it being consumed in the manufacture of soda, in that of bleaching-powder, in calico printing and dyeing, and, in fact, in most chemical operations both in the manufactory and the laboratory. In South Lancashire alone upward of 700 tons of concentrated acid are produced weekly. A process of purification is required for the acid in several of its minor applications; but for general purposes, it is sufficiently pure as supplied by the works.

SULPHURIC ANHYDRIDE, formerly known as **ANHYDROUS SULPHURIC ACID**, is commonly represented by the formula SO_3 , but there are good reasons for believing that the formula should be doubled—or, in other words, that it is a compound of two atoms of sulphur with six of oxygen. It is a colorless crystalline solid, which is tough and ductile, and can be molded in the fingers like wax without injuring the skin. It liquefies at 63° , and boils at about 112° , forming a transparent vapor if hot water be present. It unites with moisture when exposed to the air, and gives off dense white fumes. When thrown into water, the heat emitted is so great that it hisses as red-hot iron would do; and the solution has all the properties of ordinary sulphuric acid. It may be obtained by the distillation of fuming Nordhausen acid, when white fumes pass over in the cooled receiver, and solidify into a white silky-looking fibrous mass. It may be also obtained by the distillation of acid sulphate of soda (NaO.HO.2SO_3), after it has been deprived of its atom of water. It combines with sulphur, iodine, and hydrochloric acid; but both it and its compounds are of chemical interest rather than practical value. See CHEMISTRY.

SULPHURIC ETHER is a term commonly but improperly applied to ethylic, vinic, or ordinary ether (q.v.) True *sulphuric ether*, known also as *sulphate of ethyl* ($2\text{C}_2\text{H}_5\text{O.S}_2\text{O}_6$), is an oily liquid, of burning taste and ethereal odor, resembling that of peppermint, of specific gravity 1.120 (while that of ordinary pure ether is 0.720), and almost incapable of being distilled without decomposition, as at a temperature of about 280° it resolves into alcohol, sulphurous acid, and olefiant gas.

In the article **ETHER**, reference is made to the anæsthetic properties of that compound. Dr. Richardson has discovered that local insensibility may be readily induced by the application to the skin of the finely divided spray of perfectly pure rectified ether of specific gravity 0.723. The skin blanches in from half a minute to two minutes; and by following the knife with the spray, more than merely superficial incisions may be rendered painless. It has been successfully employed in amputations of fingers and toes, removal of tumors, opening of abscesses, removal of teeth, etc.

SULPHUROUS ACID some years ago became one of the most popular articles in our pharmacopœia. This sudden popularity was mainly due to the researches of a Scottish provincial physician, Dr. Dewar, of Kirkcaldy, who, from beginning his experiments on cattle, during the period of the cattle plague of 1866, extended them to other animals and to man, and obtained remarkable satisfactory results (see *Medical Times and Gazette* for 1867, vol. i., pp 492, 548). There is, of course, nothing new in applying sulphur-fumes—which in reality are composed of sulphurous acid gas—as a disinfectant. The classical scholar will recollect that Ulysses employed them to remove the unpleasant smell arising from the dead bodies of Penelope's murdered lovers. "Bring brimstone, the relief of evils," he exclaims, "and bring me fire that I may sulphurize the house."—Hom. *Od.* xx, 481, 482. It is also recorded by Ovid (*Fasti*, iv, 735) and other writers that the shepherds of Italy yearly purified their flocks and herds with "the blue smoke of burning sulphur." Professor Graham's remark, that of gaseous disinfectants, sulphurous acid (obtained by burning sulphur) is preferable on theoretical grounds to chlorine, and that no agent checks so effectually the first development of animal and vegetable life, may be said to contain all that was known with regard to the medicinal value of this gas, till Mr. Dewar began his investigations. In his experiments in connection with the cattle-plague he found that the most safe and convenient apparatus consists of a chafin two-thirds full of red cinders, a crucible inserted in the cinders, and

a piece of sulphur-stick. A piece of sulphur as large as a man's thumb will burn for nearly twenty minutes, and will suffice for a cowhouse containing six animals; and it appears undoubted that if there be due ventilation, this process may be performed four times a day for at least four months with positive advantage to the animals. When this system had been efficiently carried out—and it has been largely tried by his friends—no case of illness, not to say of death, occurred. In Mr. Crookes's report *On the Application of Disinfectants in arresting the Spread of the Cattle-plague*, that able chemist observed that "the value of sulphurous acid in arresting the progress of the cattle-plague has been proved beyond a doubt by the experiments of Dr. Dewar, and my own results entirely confirm his." His experiments in relation to the cattle-plague led Dr. Dewar to the further discovery of the value of sulphur fumigation in other departments of veterinary medicine. Peripneumonia, ringworm, mange, are among the diseases which rapidly disappear under its influence; and in the sudden undefined illnesses known in Scotland as "drows" and "towts," to which most of our domestic animals are liable, sulphurous fumigation, if applied at the outset, rarely fails to cut short the attack.

In medical practice there are three different forms, independently of the sulphites, in which sulphurous acid may be employed—viz.: (1) As the sulphurous acid of the British Pharmacopœia, which contains 9.2 per cent by weight, or about twenty times the volume of sulphurous acid gas dissolved in water; (2) in the form of spray, which escapes from the preceding compound under the action of an apparatus called a spray-producer; and (3) as a gas evolved by sprinkling at intervals small quantities of "flowers of sulphur" on red-hot cinders placed on a common shovel, resting on a stool in the middle of the room, or by burning bisulphide of carbon (*Lancet* for 1876, vol. ii, pp. 712, 811). A mixture of equal parts of sulphurous acid and water has been recommended in all cases of "breaches of the skin," as primary wounds (whether resulting from injuries or surgical operations), in ulcers, burns, bed-sores, chapped hands, chilblains, saddle-sores (whether of man or beast), sore nipples, and in cases of bruises, such as black eye, etc. Moreover, in erysipelas, its soothing properties, if diluted with two or three parts of water, are very striking. According to Dr. Dewar, the feverish irritability of young children is speedily relieved by dropping from time to time a few minims (5 to 30, according to age) of the acid on a few folds of muslin fastened on the breast: here, however, the action is not local, but is due to the evolution of the gas which is inhaled. Amongst the cases in which the acid is serviceable when applied in the form of spray or inhaled as gas, are asthma, bronchitis, catarrh, croup, diphtheria, facial neuralgia, aryngal affections, phthisis (at all events as a palliative), scarlatina, and typhoid. Dr. Dewar ascribes the healing action of sulphurous acid to its power of destroying fungi. That the acid has this power, we freely admit, but we cannot so readily admit the correctness of his view that all the diseases in which he has found it serviceable (including piles and chilblains) are dependent on fungous growths. Dr. Dewar reports a case of severe sciatica, in which immediate and perfect relief was afforded by the injection of an ounce of sulphurous acid in a breakfast-cupful of gruel into the rectum. There is one affection of this class, to which Dr. Dewar does not refer, in which it has been prescribed with advantage—viz., the form of gastric disorder in which *sarcina ventriculi* (q.v.) occurs in the vomited matter, the dose being half a dram, largely diluted with water.

None of the *sulphites* or *hyposulphites* have as yet been introduced into the Pharmacopœia. We notice them here because their action is supposed to depend upon the liberation of sulphurous or hypo-sulphurous acid when the salt comes in contact with the acid juices of the stomach. It is mainly to Dr. Polli that we are indebted for the introduction of the sulphites and hyposulphites of the alkalies and alkaline earths (soda, potash, and magnesia) into medicine. From the year 1857 to the present time he has devoted almost all his time to the study of these agents. His labors are briefly summed up as follows by Dr. Sanson in an excellent memoir on "The Germs of Cholera, and the Means of their Destruction," published Jan. 22, 1868, in the *Medical Press and Circular*: "It was found that animals could, without any apparent ill effects, swallow and absorb large doses of the sulphites. It was then observed that when the animals were killed, they long resisted the putrefactive process. Another series of experiments—and in this series 300 dogs were the basis of the deductions—showed that the sulphites exerted a prophylactic and curative power when septic poisons were introduced into the economy. Then, as regards the human subject, it was found that the stomach would tolerate large doses of the sulphites of soda or magnesia. They were tried in the various eruptive fevers, intermittent, diphtheria, typhus, typhoid, cholera, and choleraic diarrhea, pyæmia, puerperal fever, dissection wounds, malarial infection, etc. The records of cases treated in this way show an extraordinary amount of success." In a paper published by Dr. Polli himself in *The British Medical Journal* for Nov. 16, 1867, he states that since the promulgation, in 1861, of his views regarding the therapeutic value of the sulphites, no less than 158 papers on the subject have appeared; and with the exception of five or six containing certain criticisms on his labors, "all the remainder confirm, in the strongest terms, by many hundreds of detailed observations, the value of these remedies." A scruple of the salt dissolved in a wine-glassful of water flavored with tincture of orange-peel is the average dose, and it should be taken every four hours; and in some cases, as in typhoid, a grain of quinine may be advantageously added to each dose. M. de

Ricci (*Dublin Quarterly Journal*, Nov., 1866) prefers the sulphite of magnesia on the grounds that it is less unpalatable, and contains a larger proportional quantity of acid, than the soda salt. He predicts (and Dr. Sanson and other physicians of repute agree with him) that eventually the treatment of zymotic diseases by the administration of the sulphites will be as fully recognized as that of ague by cinchona.

In consequence of the powerful antiseptic properties of sulphurous acid, either in the form of gas or gaseous solution in water, and of the sulphites, these substances have been employed for the purpose of preserving meat from putrefaction. A joint of meat or a fowl submitted to a daily sulphur fumigation may be kept fit for use for many weeks. The bisulphite of lime has been found to be the most applicable of the various compounds of this class as a preservative; and Messrs. Medlock and Bailey have patented a method of preserving meat by means of a preparation of this salt. In hot weather a few drops of a strong solution of this salt will serve to keep fresh a pint of soup, jelly, milk, etc. Dr. Dewar patented a method of preserving meats by sulphurous acid, or some of its compounds; but as yet the process has not come into extensive use.

SULPICIAN, a society of priests formed in 1641 by Jean Jacques Olier for the purpose of educating priests, and deriving its name from the parish of St. Sulpice in Paris, of which he was pastor a year later. When their number had increased, a part assisted the pastor, and others took charge of a seminary. The priests of this society have conducted seminaries in France and some in America. Their institutions in France were suspended in the revolution, but in 1816 restored. Some of their members, as Olier, J. A. Emery, and Carrière have been distinguished as theologians.

SULTAN, or **SULTAN**, an Arabic word, signifying "mighty man," and evidently closely connected with the Hebrew word *shalal*, to rule, is in the east an ordinary title of Mohammedan princes, and also used in private life as a title of courtesy for people of high rank. It is given, *par excellence*, to the ruler of Turkey, who assumes the title sultan-es-selatin, or sultan of sultans. It is also applied to his mother and daughters; the word in Turkish having no grammatical gender, and corresponding also to our princess. The wife of the sultan is not now entitled to the epithet sultan or sultana.

SULU ISLANDS, an archipelago of above 60 islands in the Mindoro sea, between the Philippines and Borneo (q.v.). Cagayan Sulu, the chief of the islands, 36 m. long and 12 broad, contains the town of Soong, the residence of the sultan of the group. See **PHILIPPINE ISLANDS**.

SUMACH, *Rhus*, a genus of small trees and shrubs, of the natural order *anacardiaceæ*; having small inconspicuous flowers in panicles or in corymbs; a 5-parted calyx, 5 petals, springing from beneath a large orbicular disk; 5 stamens; a 1-celled germ with 3 stigmas; the fruit a small, nearly dry drupe, with bony *putamen*. The species are numerous, diffused over almost all parts of the world, except its coldest regions and Australia; and some of them, on account of peculiar principles which they contain, are of importance in the arts and in medicine; some are remarkable for their poisonous properties.—**VENETIAN SUMACH** (*R. cotinus*), known also as wig sumach or wig tree, is a native of the s. of Europe and w. of Asia, and is often planted in Britain as an ornamental shrub. It has simple leaves, and hairy corymbs of fruit, which have a sort of resemblance to periwigs. The wood dyes yellow; and, with the addition of other substances, green and brown, and is known in trade by the name of *young fustic*. It is largely imported into Britain. The bark is sometimes used as a substitute for Peruvian bark. The leaves are astringent, and are used for dyeing Turkey red. The root is also used in dyeing, and the whole plant is used in Italy for tanning, and is there called *scotino*. The seed resembles the almond in flavor.—The very acid fruit of the **ELM-LEAVED SUMACH** (*R. coriaria*)—a native of the countries around the Mediterranean, with pinnate leaves, not unfrequent in British shrubberies—has been used from the earliest times, as it still is by the Turks and Persians, as a condiment with different kinds of food. Both the seeds and the leaves are used medicinally, in the s. of Europe and the e. as tonic and cooling. This species is also extensively used for tanning, particularly in Turkey and in Spain. The leaves and twigs are used for dyeing black, the roots and fruit for dyeing red, and the bark for dyeing yellow.—Similar to this in its properties and uses is the **VIRGINIAN SUMACH**, or **SAG-SWORN SUMACH** (*R. typhina*), a native of almost all parts of North America, and common in British shrubberies, which has the branches curiously crooked, and covered, when young, with a soft velvety down. It has pinnate leaves, with numerous leaflets.—The **SMOOTH-LEAVED SUMACH** (*R. glabra*), a very similar species, also North American, has very acid leaves, which are eaten by children, and are used in domestic economy and in medicine on account of the malic acid which they contain. The bloom of the fruit is also very acid. This species is sometimes troublesome in North America, overrunning ground as a weed.—Of the acid and poisonous species, the most important is the **POISON OAK** (*R. toxicodendron*), of North America, a shrub from 1 to 3 ft. high, with leaves of 3 leaflets, and a milky juice, which becomes black on exposure to air. The leaves are used in medicine in cases of paralysis, amaurosis, and other nervous affections, as a stimulant of the nervous system, also in chronic rheumatism and obstinate eruptions; but are efficacious only when fresh, as the poisonous substance is volatile. Similar to this in properties are the **POISON IVY**, or **POISON VINE** (*R. radicans*), the **POISON ALDER**, **POISON SUMACH**, or **SWAMP SUMACH** (*R. venenata*), also known as dog-

wood, and other North American species, the juice of which is very acrid, and even the emanations are injurious to some persons, who from remaining a short time near these plants, or from handling them, experience swelling of the whole body, with subsequent inflammation of the skin, pustules, and violent itching, while it is remarkable that others appear quite unsusceptible of their influence.—The VARNISH SUMACH or JAPAN VARNISH TREE (*R. vernicifera*), a native of Japan and Nepal, yields a varnish much used in Japan for lacquer-work. This varnish is the juice which flows from wounds in the tree, and which becomes thick and black by exposure to the air, but is still so transparent that the finest veins of wood varnished with it may be seen through it. It is sometimes mixed with coloring matters, sometimes with gold-leaf finely ground. The expressed oil of the seeds becomes as hard as tallow, and is used for candles.

The name TANNERS' SUMACH is given to *coriaria myrtifolia*, a shrub of the s. of Europe, of the natural order *ochnaceæ*. The leaves are astringent, and are used for tanning, and for dyeing black.

SUMAT'RA (called by the Arabians *Srimat* or *Srimata*, "the happy," whence its present name), the most westerly of the Sunda islands, lies s. of the Malay peninsula, from which it is separated by the strait of Malacca. Lat. between 5° 45' n. and 5° 50' south. It is 1040 m. long and 266 m. in extreme breadth; area, 168,000 sq. m.; pop. including that of the adjacent isles, 5,000,000, about two-thirds of whom are directly or indirectly under Netherlands rule. The Europeans in 1873 numbered 2,654, not including the army in Acheen.

Physical Features.—The Barisan mountains run throughout its entire length, varying in altitude from 1550 ft. in the s.w. to 6,000 under the equator. Lofty cones, of which about 20 are volcanoes, attain to from 6,000 to upward of 10,000 feet. Another series of mountains runs parallel with the Barisan, lofty plateaux of great extent linking them together at various points. On the w. coast, a few m. of low land lie between the mountains and the sea, in some parts spurs reaching the shore in beetling cliffs. Wide alluvial plains, covered with dense jungle and forest, through which the rivers run sluggishly, forming deltas at their mouths, stretch along the n.e. coast; while the tidal action is eating into the w. coast, new ground is forming on the east.

Extensive valleys lie between the mountain chains. Several beautiful lakes are scattered over the interior. The largest is lake Singkarak or Samawang, in upper Padang, 17 m. long and 6 broad. It is 1167 ft. above the sea, and discharges its waters by the Ombilin, which flowing toward the e. coast, becomes the Indragiri.

The mountain systems are of trachyte, granite, limestone, red sandstone, and a widespread conglomerate composed of granitic and quartzose particles, the hollows in many places being filled with lava. Sienite, porphyry, serpentine, jasper, basalt, and tufa occur. Tertiary deposits are found in the valleys, and in some parts of the coasts a rich vegetable mold rests on beds of red and gray clay, or on coralline limestone. Potter's clays are met with, and gold is widely diffused. Coal, iron-ore, copper, sulphur, lead, silver, saltpeter, alum, naphtha, etc., abound.

Rivers.—Sumatra has many rivers, the most important being the Talang-Bawang; the Masi, or river of Palembang; the Djambi, Indragiri, and Siak, on the e.; the Singkel, Tabanjong, Indrapura, Moko-Moko, Bencoolen, and Padang Gadjie on the west. The capes and bays are numerous, the bay of Tapanuli being capable of containing a large fleet. A chain of islands lies parallel to Sumatra in the Indian sea. The most important are—Babi or Si Malu, Nias (q.v.), the Batû islands, North Pora, Coco island, South Pora, North Pagai, and South Pagai. To the s.e. lies Banca, rich in tin, producing also iron, lead, silver, copper, arsenic, and amber.

Climate.—The climate of Sumatra is moderately healthy, especially on the e. coast. In Tapanuli, however, are large marshes, inducing intermittent and typhoid fevers, dysentery, and other diseases. A slight increase of temperature takes place from October to March, the minimum being in May. Except in the highlands of the interior, where it is cool, the thermometer ranges from 70° Fahr., at sunrise, to 94° at 2 p.m. The monsoons are irregular, and rain falls during all the months, though the quantity in October and December is double that in February and June.

Flora.—Sumatra has many fine species of timber trees—as the djati (*tectona grandis*), the maris, a hard and heavy wood, ebony, iron-wood, etc. The magnificent *dryobalanops camphora*, and other resin-producing trees, are abundant. Several species of fig, the *uredoia elastica*, from which caoutchouc is obtained, and the gutta-percha tree (*isonandra gutta*), are numerous. In the villages the bombax, or silk-cotton tree, forms a shady resting-place at noon. The lovely *cinnamomum cassia*, the *melaleuca leucaden-drum*, which yields the medicinal capcut oil, the satin-wood (*chloroxylon srietenia*), the gigantic reed (*calamus draco*), from the ripe fruit of which the dragon-blood gum exudes, and a great variety of palms, form part of the botanical wealth of the island. Flowering plants and shrubs are numerous, and countless parasites garland the forest trees with flowers of every hue. The most curious of these is the *rafflesia* (q.v.), which, clinging to the bark of large trees, spreads out the largest known flower, with a calyx 3 ft. in diameter and 9 in. deep, and capable of containing 2 gallons of fluid.

The fruits are richer in flavor than those of Java. Among these are the guava, citron, oranges, lemon, durian, mango, bread-fruit, cocoa-nut, pomegranate, water-

melons, pine-apples, and the highly-prized mangosteen, or berry of *garcinia mangostana*. Cacao, cotton, maize, indigo, tobacco, gambier, and more especially rice, millet, pepper, and coffee, are cultivated.

Fauna.—The elephant, single and double horned rhinoceros, tiger, leopard, black bear, and tiger-cat, wild-swine, tapirs, antelopes, deer, monkeys (including the orang-outang), ant-eaters, many kinds of bat, etc., abound. Buffaloes, cows, goats, horses, sheep, and swine are kept by the natives. The peacock and the pheasants of Sumatra are of rare beauty. Hippopotami and crocodiles frequent the rivers, which have many kinds of fish, including a species of salmon.

Geographical and Political Divisions.—The kingdom of Acheen extends from the n.w. point to 98° 16' e. long., and on the e. coast at Tamiang, to 4° 22' n. lat., on the w. to 2° 22' n. lat.; area, 18,900 sq. m.; pop. about 400,000. The Dutch troops now have a strong position in the country, and will probably subdue the whole. It is well cultivated, and produces much pepper. Singkel, Tapanuli, and Lower Padang, administratively under the presidency of Padang, lie in succession to the s.e. of Acheen. Bencoolen stretches along the w. coast from 101° to 104° 40' e. long.; and the extreme s. and the e. coast, between 4° 4' and 5° 55' s. lat., form the Lampong districts. North of these is the residency of Palembang, with the kingdom of Djambi, ruled over by a native prince under Dutch control. Further n. are Indragiri, Kampar, and Siak, governed as Djambi. Between Siak and Acheen are many petty states.

People.—The natives are chiefly Malays who profess Mohammedanism. In appearance, manners, and customs, however, the inhabitants of Acheen and the Lampongs differ widely from those of other parts. The Acheenese are tall, well-made, active, and intelligent, but cunning, proud, treacherous, and blood-thirsty. They live simply, but are slaves to opium. The Lampongs are of middle stature, well-formed, of pleasant exterior, mild, but uncivilized and lazy. Caste prevails, and they follow the usages of their fathers, Mohammedanism being imperfectly known and practiced. Polygamy obtains, the wives being bought from their relatives. The houses are on posts of iron-wood, several families living under the same roof. In other parts of Sumatra the usual Malay type is found. The Kūbūs, in the n.w. of Palembang, are probably the remains of the aborigines, a harmless race who live chiefly by the chase and f-hing. Theft and murder are scarcely known among them. They believe in an after spirit-life.

Trade and Produce.—The imports and exports of the independent and half-independent kingdoms cannot be ascertained. Acheen alone produces 8,000 tons of pepper annually, and also exports gold, precious stones, cotton, raw silk, sapan wood, benzoin, camphor, sulphur, betel, etc., to the w. of India by way of Pūlu, Penang, and Singapore, receiving in return manufactured goods, salt, opium, etc. On the s.w. coast, Bencoolen, the Lampongs, and Palembang, the imports have an annual value of about £750,000; the exports to £850,000. Java has nearly half the trade, Europe and eastern countries the remainder. Imports—rice, cotton, and other textile fabrics, etc.; exports—benzoin, gum elastic, resin, pepper, rattans, cotton, coffee, drugs, ivory, dye-stuffs, edible nests, wax, tobacco, bêche-de-mer, etc. The rice-culture is extensive, the w. coast producing as much as 320,000 tons in a single year. The coffee yield varies from 5,500 tons to nearly twice as much. Upper Padang sends the largest quantity of coffee and rice, with much cocoa-nut oil, to market.

History.—Marco Polo visited Sumatra in the 13th c. Alvaro Tal-zo in 1506, and Siquera in 1509, the Portuguese then entering into trading relations with the natives. About 90 years later the Dutch under Houman reached the island, and on a second visit he was treacherously murdered at Acheen. In 1601 two ships from Zealand, with the Netherlands commissioners, gen. De Roi and Laurens Bikker, arrived; were favorably received by the king, obtained a full cargo, and returned with two Acheenese ambassadors. Later, the Dutch drove the Portuguese from their factory at Pūlu Tjinko, to the s. of Padang; and in 1666 the latter place became the seat of the Netherlands power on the w. coast. In 1795 Padang was taken by the British, and retained till 1819. A few years after, Bencoolen was also given up to the Dutch, and the southern division of the island soon fell under the same rule. Various rebellions against the Netherlands dominion have since arisen, with the uniform result of extending the power of the Dutch toward the interior and the north. In 1865 an expedition was sent to force the king of Asahan, a small state on the n.e. coast, to submit to their authority, and since 1872 they have been waging war against Acheen.—See *Flora van Nederlandsch Indië*, door F. A. W. Miquel (Amst. and Leip. 1855); *Bijdragen tot de Geologische en Mineralogische kennis van Ned. Indië, in het Natuurk. Tijdschr. v. N. I.* passim.

SUMBAWA, one of the chain of islands to the e. of Java, lies between 8° 4' and 9° 2' s. lat., and 116° 50' to 119° 15' e. long., is now divided into the kingdoms of Sumbawa, Bima, Dampo, and Sangar, each governed by its own sovereign. Area, 5,838 sq. miles. Pop. nearly 100,000. The island is mountainous, but except the volcano Tambora, which is 9,522 ft., the elevation does not exceed 5,660. The most valuable timber tree is the djati (*tectona grandis*, or Indian teak), and the tamarind is so abundant as to be little valued. Rice is extensively grown. Sapan wood is contracted for with the princes, by the Netherlands colonial government.

The natives of Sumbawa belong to the Malay race, but speak three different lan-

guages. They are inoffensive and industrious, murder, robbery, and theft being almost unknown. Many of them are Mohammedan, but the mountaineers are chiefly heathen, with an idea of a supreme being. Ancient relics recently found in Bima, indicate that they were formerly professors of Hinduism.

In 1815 an eruption of Tambora depopulated the kingdoms of Tambora and Papekat, 12,000 lives being lost, and great damage done to the whole island by the ashes. Another took place in 1836, and one of Gunong Api, in Bima, in 1860, but with little loss.

SUMBUL (see MUSK PLANT) has been extensively employed for some years past, both in this country and in America, in the treatment of epilepsy, hysteria, and other diseases of the nervous system. It has a musk-like odor, and an aromatic and somewhat bitter taste. It may be given in the form of infusion, tincture, or resin.

SUMMARY DILIGENCE, in the practice of the law of Scotland, means issuing execution without the formality of an action, as a creditor enforcing payment of a bill of exchange or of a bond.

SUMMER, a horizontal beam, called also breast summer.

SUMMER DUCK, or **WOOD DUCK**. *Dendronessa sponsa*, or *air sponsa*, a very beautiful species of duck, of the section having the hind-toe destitute of membrane, a native of North America. It is found during the breeding season in almost all parts of the United States, and as far n. as Nova Scotia, migrating southward in winter, when it abounds in Texas and Mexico, but some remain during winter even in Massachusetts. It has been found capable of domestication.—Very similar to it is the **MANDARIN DUCK** (*dendronessa* or *air galeiculata*), a Chinese species. Both of these species have the power of perching on trees. The summer duck makes its nest in the hollow of a tree.

SUMMERFIELD, JOHN, 1798–1825; b. England; educated at the Fairfield Moravian seminary; was a clerk at 14 in a mercantile house in Liverpool, and fell into bad habits; went with the family to Dublin in 1813; joined the Wesleys; became a preacher in the Irish conference, 1818; preached with eloquence and success in Ireland and England; came to America with his father, 1820, and joined the New York conference. In New York, Philadelphia, Baltimore, and Washington, his remarkable eloquence drew immense crowds from all denominations, classes, and professions. His health failing under his excessive labors he sailed for France in 1822; represented in Paris the American Bible society to the French Protestant Bible society; spent some time in England; returned to New York, 1824, and continued to travel and preach, though in feeble health. He aided in forming the American tract society. His *Sermons* and *Sketches of Sermons* were published, with a biography by John Holland.

SUMMER ISLANDS, a small archipelago of islets off the w. coast of Scotland, near the entrance of Loch Broom, an inlet in the n.w. of the county of Ross. The islets are about 20 in number; and the largest of them, Tanera, 2 m. long, and 1 m. broad, has a pop. 71, of 114.

SUMMERS, a co. in s. West Virginia, drained by the Greenbrier and Kanawha rivers and traversed by the Chesapeake and Ohio railroad; formed a few years ago from Nicholas co.; pop. '80, 8,832—8,765 of American birth, 693 colored. The surface is rough and hilly, fertile only in the bottom lands; corn, wheat, and cattle are the staples. Co. seat, Hinton.

SUMMERS, THOMAS OSMOND, D.D., LL.D., b. England, 1812; came to America, 1830; joined the Methodist Episcopal church, 1832; received into the Baltimore conference, 1835; missionary to the republic of Texas, 1840, and was one of the nine preachers who formed the first Texas conference; became a member of the Alabama conference, 1844; was secretary of the conference at Louisville, Ky., where the Methodist Episcopal church, South, was organized. He has published *A Treatise on Baptism*; *A Treatise on Holiness*; *Sunday-school Teacher, or the Catechetical Office*; *Seasons, Months, and Days*; *Talks Pleasant and Profitable*; *The Golden Censer*; *Scripture Catechism*, 2 vols.; *Questions on Genesis*; *Refutation of the Theological Works of Thomas Paine*. He was appointed in 1846 assistant editor of *The Southern Christian Advocate*; edited *The Sunday-school Visitor* for seven years, and *The Quarterly Review* of the Methodist Episcopal church, South, in 1858; was chairman of the committee appointed to prepare the new hymn book, and has edited nearly all the publications of the Southern Methodist church.

SUMMIT, a co. in n.w. Colorado, bordering on Utah, crossed by the Rocky mountains; 8,500 sq. m.; pop. '80, 5,459. There are large deposits of gold, iron, coal, lead, copper, and zinc. Co. seat, Breckinridge.

SUMMIT, a co. in n.e. Ohio, drained by the head-waters of Tuscarawas river and the Cuyahoga; 420 sq. m.; pop. '80, 43,788—26,724 of American birth, 377 colored. It is intersected by the Ohio canal, here at its highest elevation, and by the Atlantic and Great Western, the Cleveland and Pittsburg, and the Cleveland, Mt. Vernon and Columbus railroads. Its surface is hilly, diversified by lakes, and contains the long narrow valley of the Cuyahoga, 300 ft. deep. The streams furnish extensive water-power; there is a good supply of timber; rich coal beds are mined; there are sandstone, and fire clay. Large numbers of sheep and other stock are raised, and the soil produces grain, and

dairy products. The manufactures are important, embracing carriages, cooperage, lumber, leather, cutlery, and edged tools, machinery, paper, iron castings, etc. Co. seat, Akron.

SUMMIT, a co. in n.e. Utah, bordering on Wyoming; crossed by the Wasatch mountains, which rise here to a height of 12,000 ft.; 1250 sq. m.; pop. '80, 4,240. The surface is covered with vast forests. It has large deposits of gold, silver, lead, and coal. Co. seat, Coalville.

SUMMONS, in English law, means generally a writ directed to a party to appear and answer some complaint before a court or judge. It is the first writ in an action at law; and a similar writ issues incidentally both in chancery and interlocutory matters. It is also the first step in proceedings before justices. In Scotland, it is also the first writ in an action.

SUMNER, a co. in s. Kansas, having the territorial line of the Indian territory for its s. boundary; 1188 sq. m.; pop. '80, 20,812—19,589 of American birth, 114 colored. It is drained by Arkansas river, Good river, and Cowskin and Slate creeks. The surface is level prairie, containing every element of fertility. Co. seat, Wellington.

SUMNER, a co. in n. central Mississippi, drained by the Big Black river; about 400 sq. m.; pop. '80, 9,535—2,297 colored. The surface is rolling and heavily wooded. The soil is fertile. Corn, cotton, and potatoes are the principal productions. Co. seat, Walthall.

SUMNER, a co. in n. central Tennessee, adjoining Kentucky; drained by branches of the Big Barren and Cumberland, by which it is bounded s.; traversed by the Louisville and Nashville railroads; 500 sq. m.; pop. '80, 23,625—23,510 of American birth; 7,331 colored. The surface is heavily wooded and elsewhere fertile; tobacco, corn, wheat, oats, and pork, are the staples. Co. seat, Gallatin.

SUMNER, CHARLES, American statesman, was born at Boston, Mass., Jan. 6, 1811. His father was a lawyer, and for many years sheriff of the county. He was educated at Harvard college, where he graduated in 1830; studied law at the Cambridge law school; was admitted to the bar in 1834, and entered upon a large practice; edited the *American Jurist*; published three volumes of *Sumner's Reports of the Circuit Court of the United States*; gave lectures at the law school, but declined a proffered professorship; and from 1837 to 1840, visited England and the continent of Europe. On his return he edited Vesey's *Reports*, in 20 vols., and in 1845, made his *début* in politics in a 4th of July oration, on the true grandeur of nations—an oration against war and the war with Mexico, pronounced by Mr. Cobden the noblest contribution by any modern writer to the cause of peace. Identifying himself with the free-soil party, he was, in 1850, chosen U. S. senator from Massachusetts, in place of Daniel Webster, where he opposed the fugitive slave law, and declared "freedom national—slavery sectional." In 1856 he made a two days speech on "the crime against Kansas," some of which was of a violently personal character, in consequence of which he was attacked in the senate chamber, May 22, and severely beaten by Preston C. Brooks, and so severely injured that his labors were suspended for three or four years; during which he visited Europe for repose and health. Returning to the senate, he supported the election of Mr. Lincoln, urged upon him the proclamation of emancipation, and became the leader of the senate, as chairman of the committee on foreign relations. In 1862 he was again elected a senator, and re-elected in 1869. In 1871 he opposed the annexation of Hayti to the United States. He published *White Slavery in the Barbary States* (1853); *Orations and Speeches* (1850), etc. He died in 1874. A *Memoir and Letters* appeared in 1878.

SUMNER, CHARLES (*ante*). A man of great personal force and indomitable will. Mr. Sumner made his influence more distinctly felt by the American people, and more directly influenced the course of events by his personal action, than did most of his associates in the senate. Frequently on the unpopular side of important questions, he often succeeded in turning the popular mind in the direction of his own opinion, by the force of the reasoning which he brought to bear on the question at issue. Such was peculiarly the case with regard to the Mason and Slidell affair; the emancipation act; and the St. Domingo question. His oratorical efforts were invariably the result of exhaustive labor, and to the last he methodically wrote out his addresses. From the beginning of the war of the rebellion, he insisted upon the abolition of slavery; and favored the largest possible freedom of action, political and social, for the negro. His antagonism to pres. Grant's St. Domingo policy was positive and continuous; and he became so imbittered against the administration that he opposed Grant's re-election, and supported Horace Greeley in 1872. The antagonism was mutual. Mr. Sumner's friend, Mr. Motley, having been removed from the position of minister to the court of St. James in 1870; while he himself was forced out of the position of chairman of the important committee on foreign affairs in 1871, a position which he had held continuously for ten years. His last important act was to press his civil rights' bill, which placed the negro on a perfect equality with the whites in every state in the union, so far as personal rights under the law were concerned. He never recovered, it was thought, from the effects of the attack made upon him by Mr. Brooks in 1856; and in 1874 this trouble returned

to him in a serious malady of the chest, which proved fatal to him on Mar. 11 of that year.

SUMNER, EDWIN VOSE, 1796-1863; b. Boston; appointed to the army in 1819; served in the Black Hawk war on the Indian frontier, and through the Mexican war. He was dangerously wounded at Cerro Gordo, where he led the charge, and was brevetted colonel for his conduct at Molino del Rey, where he was in command of the cavalry. He was governor of New Mexico, 1851-53; led an expedition against the Cheyennes in 1857; and in 1861 succeeded Twiggs as brig.gen., and assumed command of the department of the Pacific. He was soon recalled to the e., and taking command of the 1st corps of the army of the Potomac, served through the peninsular campaign of 1862, in which he was twice wounded. The same year he became maj.gen. of volunteers, and took command of the 2d corps. He was at Fredericksburg, and early in the next year was ordered to take command of the department of the Missouri, but died on his way.

SUMNER, JOHN BIRD, D.D., 1780-1862; b. England; educated at Eton and Cambridge; ordained and appointed canon of Durham, 1820; bishop of Chester, 1828. In this district he gave a great impetus to the building of churches and the establishment of schools. In 1848 he was consecrated archbishop of Canterbury. He was a liberal in politics, and the leader of the evangelical portion of the English church. He published essays on the prophecies and on Christian evidences; the Hulse prize essay; *The Records of Creation*, which received the Burnett prize of \$400; besides several volumes of sermons and charges. His numerous theological works are distinguished "by their earnest piety, depth of thought, and elegance of language."

SUMPTUARY LAWS (Lat. *sumtus*, expense), laws passed to prevent extravagance in banquets, dress, and private expenditure. They abound in ancient legislation. The Locrian legislator, Zaleucus, 450 B.C., ordained that no woman should appear in the streets attended by more than one maid servant, unless she were drunk, or wear gold or embroidered apparel, unless she designed to act unchastely. At an early period in Roman history, the censors, to whom was intrusted the superintendence of public and private morality, punished with the *notatio censoria* all persons guilty of luxurious living; but as the love of luxury grew with the increase of wealth and foreign conquest, various legislative enactments were passed with the object of restraining it. The lex Orchia, 161 B.C., limited the number of guests to be present at a feast; the lex Fannia, 161 B.C., regulated the cost of entertainments, enacting that the utmost sum which should be expended on certain festivals was to be 100 asses, 30 asses on certain other festivals, and 10 asses on an ordinary entertainment, where also no other fowl than one hen was permitted to be served up, and that not fattened for the purpose. There were also the lex Didia, Lucretia, Cornelia, Æmilia, Antia, Julia, and others, most of them passed in consequence of the practical disregard of the similar laws that had preceded them; but they all seem to have been habitually transgressed in the later times of the republic.

Sumptuary laws were in great favor in the legislation of England from the time of Edward III. down to the reformation. Statute 10 Edward III., c. 3, narrates that "through the excessive and over-many costly meats which the people of this realm have used more than elsewhere, many mischiefs have happened; for the great men by these excesses have been sore grieved, and the lesser people, who only endeavor to imitate the great ones in such sorts of meat, are much impoverished, whereby they are not able to aid themselves, nor their liege lord, in time of need, as they ought, and many other evils have happened as well to their souls as their bodies;" and enacts that no man, of whatever condition or estate, shall be allowed more than two courses at dinner or supper, or more than two kinds of food in each course, except on the principal festivals of the year, when three courses at the utmost are to be allowed. All who did not enjoy a free estate of £100 per annum were prohibited from wearing furs, skins, or silk, and the use of foreign cloth was allowed to the royal family alone. Act 37 Edward III. declares that the outrageous and excessive apparel of divers people against their estate and degree is the destruction and impoverishment of the land, and prescribes the apparel of the various classes into which it distributes the people; it goes no higher than knights, but there are minute regulations for the clothing of women and children. This statute, however, was repealed the next year. In France there were sumptuary laws as old as Charlemagne, prohibiting or taxing the use of furs; but the first, extensive attempt to restrict extravagance in dress was under Philip IV. By an edict of Charles VI. no one was allowed to exceed a soup and two dishes at dinner. Sumptuary laws continued to be introduced in England in the 16th, and in France as late as the 17th century. Scotland had also a similar class of statutes. The Scottish parliament attempted to regulate the dress of the ladies, to save the purses of the "puir gentlemen, their husbands and fathers." There was a prohibition against their coming to kirk or market with the face muffled in a veil; and statutes were passed against superfluous banqueting, and the inordinate use of foreign spices "brocht from the pairts beyond sea, and sould at dear prices to monie folk that are very unablill to sustain that coaste." Neither in England, Scotland, nor France do these laws appear to have been practically observed to any great extent; in fact, the kings of France and England contributed far more, by their

love of pageantry, to excite a taste for luxury among their subjects than by their ordinances to repress it. Mr. Froude suggests that such statutes may have been regarded, at the time when they were issued, rather as authoritative declarations of what wise and good men considered right, than as laws to which obedience could be enforced. Enactments of this kind have long been considered to be opposed to the principles of political economy. Most of the English sumptuary laws were repealed by 1 James I., c. 25, but a few remained on the statute-book as late as 1856.

SUMTER, a co. in w. Alabama, adjoining Mississippi; bounded on the e. by the Tombigbee river, drained by Sucarnoochee creek and the Noxubee river; traversed by the Alabama Central, and the Alabama and Chattanooga railroads; about 860 sq.m.; pop. '80, 28,728—22,280 colored. The surface is rolling and heavily wooded. The soil is fertile. The principal productions are corn, cotton, and live stock. Co. seat, Livingston.

SUMTER, a co. in c. Florida, 1370 sq.m.; pop. '80, 4,686. The surface is level and partly swampy. Co. seat, Leesburg.

SUMTER, a co. in s.w. Ga., drained by the Flint river, its e. boundary, and by several creeks; traversed by the South-western railroad, about 600 sq.m.; pop. '80, 18,239—18,192 of American birth, 12,189 colored. The soil is level and fertile; cotton, corn, and pork are the chief productions. Co. seat, Americus.

SUMTER, a co. in e. central S. C., drained by the Wateree and Black rivers and Lynch's creek; traversed by the Wilmington Columbia and Augusta railroad; about 600 sq.m.; pop. '80, 37,037—36,926 of American birth, 27,064 colored. Surface level and extensively covered with pine forest, the tar and turpentine from which are, with cotton, the main exports. Co. seat, Sumter Court-House.

SUMTER, Fort (originally spelled *Sumpter*, after gen. Sumpter, in whose honor it was named), an American fort of the second class, built 1845-55, in the form of a truncated pentagon 50 ft. high, on an artificial island, at the entrance of Charleston harbor, 2½ m. distant from forts Moultrie and Pinckney, on either side. On the secession of South Carolina, Dec., 1860, maj. Anderson, in command of the defenses of the harbor, was called upon to surrender them to the state authorities. Instead of doing this, he abandoned the other forts and occupied fort Sumter, mounting 52 guns, with a garrison of 70 men and 30 or 40 workmen. This was considered an act of war by the confederates and their troops, who, under command of gen. Beauregard, took possession of forts Pinckney and Moultrie, and erected additional batteries. While the surrender of the fort was under consideration, a fleet was sent from New York for its relief. On its appearance off the harbor, the attack on the fort was opened by gen. Beauregard, April 12, 1861, and it surrendered on the 13th. This event aroused the north, and began the war, which terminated in 1865. During the siege of Charleston this fort was battered by the heaviest artillery, until its walls were completely crushed and shattered. The flag-staff was shot away fifty times, and thousands of tons of iron projectiles were mingled with the debris of the fort; but the garrison constructed a still stronger fortress on its ruins, and held it for three years against assault and bombardment, until the operations of gen. Sherman compelled its evacuation, and the United States flag was again raised, April 14, 1865; an event soon followed by the evacuation of Richmond, and the surrender of all the confederate armies.

SUMTER, THOMAS, 1734-1832, b. Va.; settled in South Carolina. He took part in the Cherokee war, and was prominent in the political movements which resulted in the revolution. He became col. of the 2nd regiment of riflemen in 1776, and remained in the state till the surrender of Charleston, when he enlisted a considerable force in North Carolina, and defeated a body of British and Tories. Soon afterward he unsuccessfully attacked the post at Rocky Mount. Within a few days he defeated the prince of Wales regiment at Hanging Rock and dispersed a large force of Tories. Routed in his turn by Tarleton at Fishing creek, he recruited another force with which he beat Tarleton at Blackstocks, but was dangerously wounded. He was made brig. gen. of the S. C. militia, and was thanked by congress. In 1781 he enlisted 3 regiments of rangers and aided Marion and other generals. He sat in the convention which formed the federal constitution; was a member of congress, 1789-93, and 1797-1802, and was U. S. senator, 1801-10. He was U. S. minister to Brazil, 1810-11.

SUMY, a t. of Russia, in the government of Kharkov, and 90 m. n.w. of the town of that name, on the Psol. It contains several factories, and has an important annual fair. Pop. '67, 14,060.

SUN, THE, the great luminary upon which not only our well-being but our very existence depends, has been from the earliest ages a source of wonder and admiration, and its worship was probably the very first form of idolatry. See SUN-WORSHIP.

When the true system of the universe became known, one of the first labors of astronomers was to ascertain the distance and size of the sun, and these have been known for some time with tolerable precision; but until lately the most vague and unsatisfactory theories regarding its chemical and physical constitution have continued to prevail.

Within the last few years, however, our knowledge of its chemical and physical con-

stitution has increased with a rapidity probably unequalled in any other branch of science.

Our knowledge regarding the sun is best arranged under three heads: viz., *The general relations of the sun to our globe; the sun's chemical constitution; and its physical constitution.*

Relations of the Sun to the Earth, as the Source of Light and Heat.—In order to appreciate the grandeur of the scale on which solar activity is carried on, it is only necessary to know a few facts relative to the sun, which are best expressed by numbers.

1. *Distance of the Sun from the Earth.*—The difficulty in ascertaining the parallax (q.v.) of the sun arises from the smallness of the base line as compared with the distance of the object. The distance of the observing stations must always be less than 8,000 m.; from this the parallax of the moon, which is only 30 times 8,000, can be observed directly with tolerable nearness. But when the distance is many thousands times the length of the base line, the triangle is "ill-conditioned" or unfavorable to accuracy, and the problem must be approached indirectly. The first attempt to measure the distance of the sun was that made by the Greek astronomer Aristarchus in the third c. B.C., who made it only about one-twentieth of what we now know it to be. Even the great astronomer Kepler in the seventeenth c. could only say that the distance must be at least between 13 and 14 millions of miles. Subsequent estimates—for, owing to the imperfection of the methods and instruments, they were little better than estimates—rose to 80 millions. At last, in 1716, the English astronomer Halley proposed a method of employing the transits of Venus. Accordingly, the transits of 1761 and 1769, were observed in a variety of places; but the results at first deduced were discordant and unsatisfactory, until in 1824 the German astronomer Encke "discussed" the observations of 1769, and arrived at a distance of about $95\frac{3}{10}$ millions of miles; and this number held its place in books of astronomy for a good many years. In the mean time, in the absence of transits, other methods, become possible through the growing perfection of astronomical instruments, were tried, and most of them concurred in pointing to a value nearly $3\frac{1}{2}$ millions less than that above stated; so that 91,500,000 came to be accepted as the approximate distance of the sun, until the transit of 1874 should settle it more definitely.

A transit can occur only when the planet is in or near one of her nodes at the time of inferior conjunction, so as to be in a line between the earth and the sun. The coincidence of these two conditions follows a rather complex law. There are usually two transits within eight years of one another, and then a lapse of 105 or 122 years, when another couple of transits occur, with eight years between them. The transit of 1874 will be followed by one in 1882, and there will not be another until June, 2,004.

The way in which a transit is turned to account may be understood by the help of the accompanying diagram, where E represents the earth; V, Venus; and S the sun. It is to be premised that the *relative* distances of the planets from the sun are well known. Their periodic times can be observed with accuracy, and from these by Kepler's (q.v.) law we can deduce the *proportions* of the distances, but not the distances themselves. It is thus known that if the distance of the earth from the sun is taken as 100, that of Venus is 72. In the fig. then, AV is 28, or about one-third of Va or Vb.

An observer at a station, A, on the northern part of the earth will see the planet projected on the sun as at *a*, while a southern observer will see it at *b*. The distance of the sun from Venus being about three times her distance from the earth, it is obvious that the distance *ab* will be three times the distance AB; and it is a great advantage to have the stations A, B, as far apart as possible, as the interval *ab* is thus increased and its measurement rendered more accurate.

But how is it measured? For each observer sees only one of the spots, and does not know where the other is; and

there are no permanent marks on the sun's surface to guide us. The difficulty is got over in the following way: Each observer notes the exact duration of the transit, that is, the time the spot takes to travel from C to D, or from F to G. Now as we know the rate of Venus's motion in her orbit, this gives us the lengths of the lines CD and FG in minutes and seconds of arc. Knowing then the angular diameter of the sun ($32'$) and the lengths of two chords CD and FG, we can easily, by the properties of the circle, find the distance *ab* between them. This gives us the angle *aAb*. In the triangle AVb, then, we know the angle at A and the proportion of the sides AV and Vb, and from that we can find the angle AbV or AbB. Now this is the quantity sought, being the parallax of the sun as seen from two stations on the earth. Whatever the distance AB actually is, the angle is reduced to correspond to a distance equal to the earth's semi-diameter. The parallax deduced by Encke, as above referred to, was only $8.5776''$, while the parallax corresponding to the other smaller measurement above stated is $8.94''$. The advantage of this roundabout procedure is that a comparatively large angle (*aAb*) is measured in order to deduce from it a smaller (*AbB*), so that any error in the measurement is diminished in the result.

The transit of 1874 was observed at more than fifty stations, astronomers from all the civilized world taking part in the work. The labor of discussing and comparing the observations has not yet been overtaken, but several partial results have been announced,

which still show considerable discrepancy. The chief source of uncertainty arises from the difficulty the observers found in determining the exact moment of "ingress" and "egress" of the planet, owing to the dense atmosphere of the latter rendering the limbs of the two bodies indistinct and distorted. Much was expected from the multitude of photographic pictures taken, but they have proved a failure. They are said to lack the necessary sharpness, and to be liable to other sources of error. The first partial discussion of the British observations gave, according to the astronomer royal, a result of $93\frac{1}{2}$ millions of miles. A more extended discussion since announced results in $92\frac{1}{2}$ millions of miles.

It is hoped that when the transit of 1882 comes, the defects of the photographs, as well as the uncertainty of the time-observations, may be obviated. In the meantime astronomers are turning with greater hope to other methods, especially to observations of Mars, and of some of the minor planets. From observations of Mars made in 1862, the American astronomer Newcomb deduced a distance of $92\frac{1}{2}$ millions of miles. The velocity of light, which has been determined by the ingenious optical experiments of Foucault and others, has also been pressed into the service of the problem. The aberration of light (q.v.) results from the relation of the velocity of light to that of the earth's motion in her orbit; and from the observed amount of the aberration we are thus able to deduce the earth's velocity. From knowing then the time of the earth's revolution, we can find the circumference of her orbit, and hence her distance from the sun. The most careful investigation by this method gives a distance of 93 millions of miles. An ingenious method of observing the parallax of Mars at its opposition, first suggested by the astronomer royal, but carried out by Mr. Gill on the island of Ascension in 1877, promises still more satisfactory results. The essence of the method consists in this, that instead of depending upon two sets of observers at different parts of the earth, one observer and one station are made to suffice. One observation is taken in the evening when the planet is rising, and another in the early morning when it is setting. In the mean time the rotation of the earth has transported the observer 6,000 or 7,000 m. through space, and this forms his base line. Mr. Gill's observations were made by means of the heliometer, the most effective of instruments for such purposes. From such of his observations as had been reduced at the end of 1878, Mr. Gill announces his belief that the sun's distance will prove to be nearer to 93 than to 92 millions of miles.

The other important numerical facts relative to the sun are the following: Its *diameter* calculated on the basis of the shorter distance hitherto received, is, in round numbers, 850,000 m., or more than 107 times the mean diameter of the earth; so that the *volume* or bulk of the sun exceeds that of the earth 1,200,000 times, and is 660 times greater than the bulk of all planets at present known, together. The *mass* of the sun, or quantity of matter it contains as measured by weight, exceeds that of the earth only 300,000 times; and thus it appears that the matter of the sun has only one-fourth the density of that of the earth. From this and other facts, it is inferred that the matter of the sun exists for the most part in a gaseous condition. Still his mass is 740 times greater than the masses of all known planets put together. The *period of rotation* of the sun upon its axis, which Galileo was the first to calculate from observations of the sun-spots, and which takes place in the same direction as that of the earth, is about 25 days 8 hours. It appears, however, that this period varies according to the solar latitude of the spots from which it is calculated. The *inclination* of the axis of the sun to the ecliptic is about $7\frac{1}{2}^{\circ}$, and the *longitude of the ascending node* is about $74^{\circ} 30'$.

2. The form or *figure of the sun* has been the subject of recent investigations. The polar and equatorial diameters of the sun's disk as observed, have been supposed to differ, though by a very small quantity only. The photographs of the sun do not quite agree in the amount of the value for the diameter with that given by observations.

The general laws by which the relation of our earth to the sun, as the source of light and heat, is governed, are of the most simple kind. The rays which emanate from the sun's disk into space proceed in diverging lines, and, on arriving at the earth, their intensity will be inversely proportional to the square of the sun's distance. This may be called the primary law; but the more obvious phenomena of solar heat and light are manifested to us under a secondary law depending on the obliquity of incidence of the sun's rays. See CLIMATE, EARTH, TEMPERATURE, etc.

3. *Chemical Constitution of the Sun.*—Astronomy has weighed and measured the sun long ago, and in our days chemistry, aided by physics, makes an analysis of it. The way in which this surprising result is arrived at, is explained under SPECTRUM. The main fact on which the method rests is briefly this: that a substance, when comparatively cold, absorbs the very same rays which it gives out when heated. Hence it was inferred by Kirchhoff that if there was sodium or iron in a comparatively cold state in the solar atmosphere, above the source of light, these substances would produce black lines corresponding in spectral position with the bright lines which they give out when heated. On this principle the presence in the solar spectrum of hydrogen, magnesium, calcium, sodium, and metals of the iron group has been ascertained with something like certainty. There are less clear indications of other metals, such as zinc and lead; while metals of the tungsten, antimony, silver, and gold classes have been searched for in vain. Of the metalloids, such as oxygen, carbon, nitrogen, sulphur, and the like, none had been detected till, in 1877, prof. Henry Draper of America announced the discovery

of oxygen. The presence of these substances in the sun is hardly doubted, but their identification is difficult. A chief source of complication in research of this kind is the effect on the spectra of substances produced by differences of temperature and pressure. Excessive heat seems to dissociate the groups of atoms forming the molecules into simpler groups, and thus produces a different spectrum difficult to recognize. The labors of Lockyer, Huggins, Draper, and others are directed toward overcoming these and other obstacles.

4. *Physical Constitution of the Sun.*—Since the first discovery by Galileo of those remarkable phenomena on the sun called *sun-spots*—dark patches with an area frequently exceeding several times the surface of the earth—an immense variety of theories as to the probable constitution of the solar body has been brought forward by nearly every observer. Solar photography promises valuable aid in this research by enabling us to keep a permanent record of passing phenomena, ready at any time for deliberate measurement and comparison.

One of the most important discoveries in connection with sun-spots, science owes to Dr. Alexander Wilson of Glasgow, who, in the year 1769, observed certain general and remarkable features of sun-spots, which enabled him to establish the significance of these phenomena for a solution of the question as to the sun's physical constitution. These features are as follows: When a spot was near the middle of the sun, it was found to consist of a dark *central* part, called the *nucleus* or *umbra*, and *around this* was a comparatively brighter envelope, called the *penumbra*, and at such a time both parts were distinctly visible. But as the spot approached one border, the penumbra on the side nearest the observer became gradually more and more foreshortened, while the penumbra on the other side grew broader and broader, and at length, as the spot was disappearing—that is, passing the edge of the limb—the near side of the penumbra, as well as the dark central part, entirely vanished, nothing remaining except the opposite penumbra. When a spot made its appearance on the other side of the border, Wilson noticed the same phenomena in an opposite order, and soon discovered that they were nearly universal. It followed from these observations at once that every spot presents the appearance of a funnel-shaped opening in the sun's body, which, by the rotation of the latter, successively presented the described appearances. These observations have been abundantly confirmed by the photographic records of Messrs. De la Rue, Stewart, and Loewy.

Schwabe showed, as the result of nearly 40 year's observations, that the number of groups of sun-spots is not the same from year to year, but has a maximum about every 10 or 11 years; and gen. Sabine recorded the wonderful fact that the various epochs of maximum spot frequency are also those of maximum disturbance of our earth's magnetism. Here, then, we have a very curious bond of union between the sun and the planets of our system.

It was next shown by Carrington that sun-spots have a proper motion of their own—those near the solar equator moving faster than those near the poles.

While spots are darker than the general surface of the sun, there are also frequently observed patches brighter than the general surface. These are called *facule*, and they generally accompany spots, most frequently in their wake; but they are only distinctly visible near the sun's limb, and lose their specific luminosity near the center of the sun's disk.

Another phenomenon connected with our luminary is not less remarkable than sun-spots. This is the red flames, or *protuberances*, which were first observed surrounding the sun's disk on the occasion of a total eclipse, but which by ingenious methods of observation can now be rendered visible even when the sun is not eclipsed. This colored envelope, less brilliant than the *photosphere*, or light-giving surface, and having a mean height of 5,000 or 6,000 miles, is known as the *chromosphere*, and seems to consist mainly of incandescent hydrogen, jets of which are seen at times to be projected to a height of 200,000 miles. The velocity of these movements has been calculated to exceed at times 120 mile a second. Above the chromosphere there is a far deeper layer of cooler, sub-incandescent gases, among which is an unknown substance, which chiefly composes the outer portion, and is apparently lighter than hydrogen. These gaseous envelopes, extending together to 300,000 or even 500,000 miles above the photosphere, are now believed to cause the appearance called the *corona*, or white halo, which is seen to surround the dark body of the moon during an eclipse of the sun.

If a spot be a hollow, as we have reason to suppose, it is only necessary to believe that there has been a descending current of this cold absorbing atmosphere to account for the want of luminosity. In like manner, on this hypothesis, a facula will be a portion of the luminous matter, which has been removed high up into the atmosphere, and which thus escapes the absorbing influence of the atmosphere. A spot may thus be supposed, to be produced by two currents—one ascending, and carrying the hot luminous matter up; the other descending, and carrying the cold atmosphere down. The photosphere is thus in a constant state of agitation like ebullition.

Spots and their accompanying facule are an indication of the activity of those "convection currents" by which heat is brought to the surface to replace what has been radiated off. Their temporary prevalence then is held to be a sign of more than ordinary solar activity or expenditure of energy. This is palpably manifested on our globe in the greater magnetic disturbance that takes place when sun-spots are numerous, as

before mentioned. The diurnal range of the magnet freely suspended in the Kew observatory, shows an unmistakable correspondence with the waxing and waning of the spotted area on the sun; and the frequency of aurora is found to be in perfect correspondence with prevalence of spots. It is natural to seek to connect cycles of weather with the spot-period of the sun, but nothing has yet been conclusively established. A coincidence has seemingly been made out between the recurrence of famines in southern India through deficient rain and the period of minimum spots; but the coincidence does not hold for other localities. Attempts have even been made to bring commercial crises and other recurring events into the spot-cycle.

As to the cause of the periodicity of sun-spots, observations made at Kew seem to establish a connection between the behavior of spots and the proximity of prominent planets; and it may thus be found that the recurrence of certain planetary positions in some way determines the spot-cycle.

SUN AND FIRE WORSHIP. All investigation tends to show that nature-worship was the basis of all polytheistic religions, and that the chief deities of the several mythologies were originally personifications of the sun, or of particular influences of the sun. The original solar nature of Jupiter, Zeus, Odin, Baal, Amen Ra (see EGYPT), Indra, etc., can hardly be mistaken. See those heads; also SCANDINAVIAN MYTHOLOGY, PHENICIA; and for a full development of the subject, Max Müller's essay on *Comparative Mythology* (Oxford Essays; 1856). The actual sun, however, still continued an object of worship, more especially as in the abstract and more strictly personal gods, moral and intellectual attributes came to predominate over and obscure the physical (see HELIOS); and with the worship of the sun was more or less closely associated that of fire—his representative on earth. *See PARSEES, NEEDFIRE, BELTEIN.

The most complete system of sun-worship that we have any account of is that existing in Peru when discovered by the Spaniards (1526). "Our northern natures can hardly comprehend how the sun, and the moon, and the stars were imaged in the heart of a Peruvian, and dwell there; how the changes in these luminaries were combined with all his feelings and his fortunes; how the dawn was hope to him; how the fierce mid-day brightness was power to him; how the declining sun was death to him; and how the new morning was a resurrection to him; nay, more, how the sun, and the moon, and the stars were his personal friends, as well as his deities; how he held communion with them, and thought that they regarded every act and word; how, in his solitude, he fondly imagined that they sympathized with him, and how, with outstretched arms he appealed to them against their own unkindness, or against the injustice of his fellow-men."—Helf's *Spanish Conquest of America*. The Incas, as the Peruvian monarchs were called, claimed to be children of the sun, and his representatives on earth. Their government was a despotic theocracy, of which the Inca was both high-priest and king. In Cuzco, the capital, stood a splendid temple to the sun, all the implements of which were of gold. On the w. end of the interior was a representation of the sun's disk and rays in solid gold, so placed that the rising sun, shining in at the open e. end, fell full upon the image, and was reflected with dazzling splendor. In the place or square of the temple, a great annual festival was held at the summer solstice. The multitude, assembled from all parts of the empire, and presided over by the Inca, awaited in breathless solemnity the first rays of their deity to strike the golden image in the temple, when the whole prostrated themselves in adoration. Sacrifices, similar to those of the Jews, were offered on the occasion, and bread and wine were partaken of in a manner strikingly resembling the Christian communion.

"It must not be supposed that the sun alone absorbed the devotion of the Peruvians. There was little in nature that they did not contrive to make a deity of. The moon, as the spouse of the sun, the planet Venus as his page, the Pleiades, and the remarkable constellation of the southern cross, were minor deities. The rainbow and lightning were also worshiped as servants of the sun; and fire, air, earth, and water were not without adoration."

SUNAH'SEPHA is, in the ancient legends of India, the son of a poor Brahman, Ajigarta, who was sold by his father for 100 cows to *Havis'chandra* (q.v.), and offered by the latter as a victim to Varun'a, instead of his own son Rohita, whom he had pledged himself to sacrifice to this god. The legend relates that when Sunahsepsha was bound to the sacrificial post by his own father—for no priest could be found to perform the ceremony—and when his father came whetting his sword to kill him—for neither was any priest to be found who would perform such a sacrifice—Sunahsepsha prayed in succession to the gods Prajapati, Agni, Savitri, Varun'a, again to Agni, then to the Vis'w-Devâh', Indra, the As'win, and the dawn; and while he praised the dawn with three verses, at the delivery of each verse his fetters became looser, and when the last verse was said, he became free again. He left afterward the family of his parents, and was adopted by *Vis'wamitra*, under the name of Sunah'sepha Devarâta (the God-given). The *Aitareya Brâhmana* (see VEDA), where this legend is related, also ascribes to him the first performance of some Vedic ceremony.

SUNART, Loch, an inlet of the sea in the extreme w. of Argyleshire, Scotland, having the districts of Ardnamurchan and Sunart on the n., and that of Morven on the

s.; length, inland from the Sound of Mull, 19 m.; breadth varies from 3 m. to 3 furlongs. At its head stands the village of Strontian.

SUNBIRDS, *Cinnyridæ*, a family of birds of the order *insessores* and tribe *tenuirostres*, which may be regarded as a connecting link between the creepers and the humming-birds, and as occupying nearly the same place in the tropical parts of the Old World which belongs to the humming-birds in America. They are all of small size, although none are so small as the smallest humming-birds; they rival humming-birds in brilliancy of plumage, and like them they feed on the juices of flowers, which they suck by their long bill; they do not, however, flutter on the wing when feeding, like humming-birds, but perch on or beside the flower into which the bill is to be inserted. The species are very numerous, and are natives of the southern parts of Asia, the eastern Archipelago, and Africa. The resplendent metallic plumage belongs only to the male, and only to the breeding season.

SUNBURY, a co. in s.e. New Brunswick, crossed by the European and North American railroad and the Fredericton branch; drained by St. John's river; 1200 sq.m.; pop. 71, 6,824. The surface is mostly level and densely timbered; the soil is fertile. Co. seat, Oromocto.

SUNBURY, a borough of Upper Augusta township, Northumberland co., Penn., near the junction of the branches of the Susquehanna, about 55 m. from Harrisburg, on the Northern Central railroad; pop. 70, 3,131. The place has some importance as a railroad junction and coal-shipping station. There are 2 machine-shops, 2 foundries, a daily and 3 weekly papers, and a bank.

SUNDA ISLANDS, that great chain of islands belonging to Malaysia, running e., commencing with Sumatra (q.v.), and ending with Timor (q.v.), and separating the Java sea from the Indian ocean. Sunda strait is a passage, from 70 to 90 m. in breadth, between Sumatra and Java.

SUNDAY. See **SABBATH**; **LORD'S DAY**; **PUBLIC-HOUSES**.

SUNDAY-SCHOOLS were founded about the close of the year 1781 by Robert Raikes, a printer in Gloucester. Business leading him into the suburbs of the town, inhabited by the lowest class of the people, he was struck with concern at seeing a group of children, miserably ragged, at play. He was informed that "on Sunday the street was filled with a multitude of wretches, who, having no employment on that day, spent their time in noise and riot, playing at chuck, and cursing and swearing." To check this deplorable profanation of the Lord's day he engaged four women, who kept dame schools, to instruct as many children as he should send them on the Sunday, in reading and the church catechism, for which they were to receive one shilling each. In a short period a visible improvement was effected both in the manners and morals of the children, who came in considerable numbers; they attended church with their mistresses, and a great many learned to read and say their catechism. Such was the origin of the Sunday-schools. This excellent scheme was noticed in the Gloucester newspaper in 1783; but a letter of Mr. Raikes, from which the above account is taken, published in the *Gentleman's Magazine* in 1784, first drew general attention to it. Numerous schools, formed on the same model, sprang up in all the principal towns; and a society, under high patronage, was formed in London in 1785 for the establishment and support of Sunday-schools throughout the kingdom, which in 14 years expended £4,000 in payment of teachers. Her majesty, queen Charlotte, admitted Mr. Raikes to an audience, and expressed her high approbation of his plan. This was the first stage of the Sunday-school. The great impediment to its prosperity was the expense of hiring so many teachers. Even in Gloucester, the birthplace of the Sunday-schools, after Mr. Raikes's death in 1811, all the Sunday-schools were closed for a time owing to want of funds. Whoever first conceived the idea of gratuitous instruction has nearly as great merit as Mr. Raikes himself; but probably it was suggested by necessity to many minds in different places at the same time. It was the means of starting Sunday-schools on a new career of success, and the idea spread so rapidly that, by the year 1800, the teaching was almost universally gratuitous. A higher class of teachers offered their services; the schools ceased to be filled by the very poorest alone; handsome buildings were erected in connection with the different churches and chapels, or by general subscription, and that system was organized which has covered the land with schools. The secular teaching, which in certain instances included writing and arithmetic, was not of a very high order; but it placed the key of knowledge in the hands of multitudes who would otherwise have been unable to read; and the religious instruction with which it was combined has molded the character of some of the best men in England. In 1803 the Sunday-school union was formed, which, by its numerous publications, its traveling agents, and its connection with branch societies in every part of the kingdom, has exercised great influence on the Sunday-school cause. The institute of the church of England, which operates in a similar manner, is of later date. Within the last 20 years the Sunday-school has entered upon a third stage of its history. The improvement and multiplication of week-day schools obviate the necessity for teaching reading in Sunday-schools, so that they have gradually become restricted to religious instruction. This for a time threatened to affect their popularity, but as the teachers were earnest men they culti-

vated the art of teaching with considerable success. Sunday-schools have prospered in Scotland, where religious teaching alone ever prevailed, and the stability of this modern invention is accomplished.

The Sunday-school found its way into Scotland as early as the year 1752; but it was not till 1786, when the society for promoting religious knowledge among the poor was formed, that it was publicly recognized; nor till 1797, when the gratis Sunday-school society was originated, that schools became general. At first they met with considerable opposition from portions of the ecclesiastical courts, but they are now supported by all the churches. Sunday-school unions exist in Edinburgh, Glasgow, and most of the large towns. The names of Dr. Chalmers, James Gall, the author of the *Lesson System*, and David Stowe, the author of the *Training System*, deserve mention in connection with the progress of Sunday-schools in Scotland. In Ireland Sunday-schools had been partially anticipated in county Down in 1770; but it was not till 1785 that the system pursued by Mr. Raikes was adopted, since which its history has been analogous to that of England. The Sunday-school society for Ireland was established in 1809. Sunday-schools were introduced into New York in 1816, through the exertions of some benevolent ladies, from which they have spread themselves through the United States. They are now to be found wherever the English tongue is spoken. They thrive vigorously in the Protestant churches of France; and more recently have been planted in parts of Germany and Italy. The Roman Catholics, in this country at least, have numerous Sunday-schools. It is stated on good authority that there are in the United Kingdom about 300,000 teachers and 3,000,000 scholars; and in the United States there are 750,000 teachers and nearly 6,000,000 scholars. Of the teachers and scholars elsewhere it is not easy to form any estimate.

SUNDAY-SCHOOLS (*ante*). The first permanent Sunday-school organization in the United States, of which there is authentic record, was The First-day or Sunday-school society, formed in Philadelphia, 1791. It was composed of members of different denominations including the society of Friends. Its constitution required that the instruction given in its schools should be "confined to reading and writing from the Bible, and such other moral and religious books as the society may direct." The New York Sunday-school union was instituted, 1816; the Philadelphia Sunday and adult school union, 1817. These three societies recognized the union of different denominations, and led to the organization of the American Sunday-school union at Philadelphia, 1824. The suggestion that such an association should be formed came from New York. Its object was to concentrate the efforts of Sunday-school societies in different sections of the United States, and to endeavor to plant such schools wherever there is a population. As the new states were settled and the various religious denominations were strengthened, more attention was given by each to its own Sunday-schools, and denominational unions to promote them were formed. In the early history of the schools the chief thing expected of the children was to commit to memory portions of scripture, and the chief employment of the teachers was to hear the recitations. Afterward the question book was added to the recitation, and at length in a great degree superseded it. Still later came the lesson helps, golden text, blackboard exercises, etc. In the first schools, reward tickets were given, and when they had sufficiently accumulated were exchanged for books. This stimulated the production of volumes of suitable character, and from this the Sunday-school library has been developed. At the Robert Raikes centenary held in London, 1880, the following statistics for the United States were reported: Number of Sunday-schools in all the states and territories 82,216, containing 886,328 teachers and 6,625,124 scholars.

SUNDERBUNDS, a tract of British India, presidency of Bengal, consists of a number of low islands, forming the delta of the Ganges. The tract extends e. from the mouth of the Hoogly to the island Rahanabad, is 158 m. long, 75 m. broad, has an area of 5,341 sq. m., and an inconsiderable population. The islands are separated from each other by narrow channels, through which the waters of the Ganges force their way to the sea. The chief channels (14 in number) are navigable for the largest craft used in inland navigation. In such of the islands as have not been cleared, luxuriant woods abound, and afford lairs for the tiger, wild bear, and other ferocious animals. Government has commenced vigorous operations for the clearing of the islands, and grants of land are offered to settlers at a nominal rate. The climate, though improving, and capable of further improvement, is, as might be expected, very unhealthy. Rice, sugar, and indigo are produced in the cleared districts. Large quantities of fish, obtained in the waters of the Sunderbunds, are sent to Calcutta. Large and fierce alligators abound in the channels.

SUNDERLAND, a thriving municipal and parliamentary borough and sea-port, in the county of Durham, 13 m. n.e. of the city of that name, at the mouth of the Wear. The town may be said to be co-extensive with the parliamentary borough, and to include the suburbs of Bishop-Wearmouth on the s. bank, and Monk-Wearmouth and Southwick on the n. bank of the river, connected with Sunderland proper by an iron bridge of one arch, 236 ft. long, and nearly 100 ft. above the river at low water. The bridge over the Wear was erected in 1796, but was repaired and widened in 1858 by Robert Stephenson (q.v.), at the cost of about £40,000. On both sides of the river there are extensive wet

docks, much of the area of which has been reclaimed from the sea. The harbor, which is defended by batteries, is formed by two great piers, one 650 yards and the other 590 yards in length; and the port is resorted to by vessels of the largest tonnage, from all commercial countries. In 1875, 3,169 vessels, of 820,137 tons, entered, and 8,908, of 2,177,128 tons cleared the port; in 1877, goods (chiefly coals) worth £706,611 were exported. After Newcastle, Sunderland is the greatest coal-shipping port in the world. The sanitary condition of the town has been recently greatly improved; a large new infirmary was built in 1867, and in 1868 a spacious workmen's hall. Ship-building is one of the principal branches of industry. Glass, earthenware, ropes and chains, anchors, and other iron-wares, are very extensively manufactured. The public park of Sunderland, about 70 acres in extent, is adorned with a bronze statue of gen. sir Henry Havelock, a native of the town, and commands a fine view of the sea. The village of Roker, a mile from the town, is much resorted to for sea-bathing. Fishing is carried on to a considerable extent. Pop. of parliamentary borough, which returns two members to the house of commons (1871) 104,409; of municipal borough, 98,242.

SUNDERLAND, ROBERT SPENCER, second Earl, was the only son of HENRY, first earl, who had been raised to the peerage in 1643, for his exertions in the royal cause. He was born in 1642, and after serving as ambassador to several courts, became in 1679 secretary of state. He had by this time manifested remarkable talent. Bishop Burnet says of him, "He had a superior genius to all the men of business that I have yet known." At first, he united with Essex and Halifax in opposing Shaftesbury, who wished to set Monmouth on the throne, and favored the exclusion of the duke of York. He encouraged the king to persevere in the degrading French alliance, and, with the duchess of Portsmouth, to whom he attached himself, negotiated a treaty by which, in consideration of an annual pension from the French king, Charles was to agree to assemble no parliament for three years. Before the end of the year, he had shaken off Essex and Halifax; and a new triumvirate, consisting of himself, lord Hyde, and Godolphin, succeeded to the confidence of Charles II. The treaty with France was broken off, and Sunderland, who was now afraid of the whigs, engaged the king in a more popular alliance with Spain. After the dissolution of the last of the exclusion parliaments, he lost his office; but the duchess remained faithful to him in disgrace; and by her influence, and that of lord Rochester, he was, in 1682, says Bishop Burnet, "upon great submission made to the duke [of York], again restored to the secretary." He remained in office until the accession of James II., when his influence in the ministry became greater than ever. He who had so often saved himself in the former reign by the influence of the duchess of Portsmouth, now secured himself another patroness in the king's second wife, the princess of Modena. Although there is reason to believe he gave some encouragement to Monmouth in his rebellion, he managed, with consummate art, to obtain the entire confidence of James, and in 1685 became prime-minister. He was intrusted with a knowledge of the king's intention to establish the Roman Catholic religion as the national church, and was indeed the only minister in whom the king confided. In 1687 he privately conformed to the Roman Catholic church, and afterward openly professed his conversion. His influence was so great, that James would grant no favor until he had asked the question, "Have they spoken to Sunderland?" and when told that this nobleman got all the money of the court, he would reply, "He deserves it." Yet we find him about this time in correspondence with the prince of Orange, afterward William III. The princess Anne described Sunderland as "the subtillest workingest villain that is on the face of the earth." Burnet says he entered into a particular confidence with the prince of Orange, which he managed by his uncle, Mr. Sidney, who was sent envoy to Holland. With profligate but masterly dexterity, he contrived to deceive both his master and Barillon, and to keep them in ignorance of the events that were passing in Holland. When the prince arrived in England, Sunderland and his wife went to Amsterdam, whence he wrote to the new monarch, claiming his favor and protection on the ground that he had all along been in his interest. In 1691 he was allowed to return to England, and to kiss the king's hand. In 1695 William III. spent a week at Sunderland's house at Althorpe. It was imputed to him that he had changed his religion, in the late reign, in order the more effectually to ruin king James; and it was generally believed that he had rendered king William, when prince of Orange, some signal services, which no one else could have done. This belief gained credit from the favor shown him by William. He was made lord chamberlain, and as such took his seat at the head of the council table. After directing affairs as the acknowledged head of the government, he resigned office in 1697, and retired to private life. He spent the rest of his days at Althorpe, where he died in 1702. He never shone as a public speaker. He had, however, unusual abilities for business, and a rare skill in the art of insinuation. He possessed exquisite courtly talent, extraordinary versatility, and a flexibility of principle too common in his day, but carried by him to the most reprehensible lengths. By his wife, Anne, daughter of the second earl of Bristol, he left CHARLES SPENCER, third earl, who was born in 1674. He was described by Evelyn as a youth of extraordinary hopes, very learned for his age, and ingenious. He was for some time secretary of state in the reign of queen Anne, and under George I. rose to be all-powerful; but in 1721, being accused of receiving £50,000 worth of the fictitious stock distributed by the direc-

tors of the South Sea scheme (q.v.), in order to bribe the government, he was acquitted only by an inconsiderable majority and that from party considerations, and the indignation of the public made him resign his office. He died in 1722, not without suspicion of having intrigued, after his fall, for the restoration of the Tories, if not for the return of the pretender. Sunderland was a type of the political morality, or rather immorality, of a disgraceful age, when the greatest statesmen made no scruple of sacrificing either their own party, or the interests and dignity of the nation, to personal ambition. His title descended to CHARLES, his second son, who succeeding, 1733, to the honors of his illustrious grandfather, John Churchill, the earldom of Sunderland became absorbed in the dukedom of Marlborough. His third son, JOHN, was ancestor of the earls Spencer.

SUN-DEW, *Drosera*, a beautiful and interesting genus of plants of the natural order *droseracea*, three species of which are natives of Britain, found in bogs and moist heathy ground. The most common is the ROUND-LEAVED SUN-DEW (*D. rotundifolia*), which is plentiful in almost all places suitable to the plant. The leaves all spring from the root, and spread out in a rosette, from the center of which springs the flower-stem or scape, with a raceme of flowers all on one side. The leaves of this and the other species are fringed and beset in all parts with hairs, which bear at their extremity viscid glands, and the irritation of these glands causes them to contract and fold up, so that insects are imprisoned by them. Recent observation has proved that these insects are actually digested by the plant, their nutritive material being absorbed by it. Compare the *dionæa* (q.v.), and see Darwin's *Insectivorous Plants* (1875). The whole plant is acrid, curdles milk, and has a reputation for removing corns, bunions, and warts. An agreeable liquor, called *rossoli* (*ros solis*) is made by infusing the plant in brandy, with sugar, etc.

SUN-DIAL. See **DIAL**.

SUNFISH, *Orthogoriscus*, a genus of fishes of the family *diodontidae* (see **DIONOX**), having the body compressed, and not capable of inflation, as in the other *diodontidae*; abruptly terminating in a very short tail; the dorsal and anal fins long and pointed, united to the short tail-fin; each jaw furnished with a cutting edge of bone instead of teeth. The species chiefly inhabit the seas of warm climates, but two are occasionally seen on the coasts of Britain. The SHORT SUNFISH (*O. nola*), when young, is almost perfectly round, but becomes rather more elongated when full grown. The name sunfish is variously regarded as derived from the form of the fish, and from its habit of floating at the surface of the water in fine weather, as if to enjoy the sunshine. It attains a large size, being sometimes more than six ft. in length, and is captured by sailors. Its flesh is white and well flavored, somewhat resembling that of the skate. The liver yields a large quantity of oil, which is in repute among sailors as an external application for the cure of sprains, rheumatism, etc. The OBLONG SUNFISH (*O. oblongus*), of which specimens have also been taken on the British coasts, but more rarely, is of a longer form. It also attains a large size. The sunfishes feed upon sea-weeds.

SUNFLOWER, *Helianthus*, a genus of plants of the natural order *compositæ*, suborder *corymbifera*, having large flowers; the florets of the ray strap-shaped, without stamens or pistils, yellow or orange; the florets of the disk tubular, perfect, yellow or purplish-brown; the flowers solitary or in corymbs, with an involucre of numerous leaves; the fruit compressed, with a pappus of two or more deciduous scales. The species are numerous, all natives of America; large herbaceous plants, with opposite or sometimes alternate undivided leaves. The ANNUAL SUNFLOWER (*H. annuus*), common in our flower-gardens, is a native of tropical America, where it sometimes attains a height of 20 feet. The stem is thick and rough; the flowers solitary, and from one foot to two feet in diameter, nodding; the leaves heart-shaped-ovate. This plant is now cultivated in almost all parts of the world, and in the s. of Europe is sometimes a field-crop; the seeds being valued as food for cattle and poultry, and on account of the oil which they yield, which is little inferior to olive oil. An acre of good land produces about fifty bushels of seed, each bushel yielding a gallon of oil. The seeds are also used like almonds for making demulcent and soothing emulsions; and in some parts of Europe, a bouilli is made of them, which is used as food for infants. The American Indians make bread of them. The flowers abound in honey, and are much frequented by bees. The leaves are good fodder for cattle. The stems are used for fuel, and yield much potash.—The Jerusalem artichoke (q.v.) belongs to this genus.

SUNFLOWER, a co. in n.w. Mississippi, traversed centrally by the Sunflower river; 720 sq.m.; pop. '80, 4,661—4,587 of American birth, 2,895 colored. The surface is low, swampy in some sections; a large proportion woodland. The soil is fertile, producing cotton, grain, sweet potatoes, and live stock. Co. seat, Johnsonville.

SUNN, *Crotalaria* (q.v.) *juncæa*, a leguminous plant, native of India, which has been in general cultivation there from time immemorial, for the fiber of its bark. It has a strong general resemblance to Spanish broom. It is, however, an annual plant. The plant is cultivated not only for its fiber, but as food for milch-cows. The seed is generally sown in April or May, and in August it is pulled, or cut close to the ground—when grown for its fiber—laid in long rows till the leaves begin to rot and separate from the stalks, and steeped in water for a few days, till the bark separates freely. The

fiber is not so strong as hemp; but good cables, canvas, and cloth are made of it. It is now imported in considerable quantity into Britain. It is known by various names. *Tuag* is one of its Indian names, and it is sometimes called *brown hemp*, *Bengal hemp*, etc. The confusion of names makes it difficult to ascertain the quantity imported.

SUNNA (Arab. custom, legal usage), originally denotes among Moslems the sayings and the example of Mohammed and his community, provided they are in accordance with the Koran, the meaning of which, however, is itself explained by the Sunna. The term is therefore (though incorrectly) used for the collections of moral and legal traditions traced to the prophet, which supplement the Koran, somewhat like the Mishna (q.v.), which supplements the laws of the Pentateuch. The Sunna not only comprises religious doctrines and practice, but also civil and criminal laws, and the usages of common life: the way to eat and to drink, and to dress, and the like. This tradition is first heard of during the civil laws among the adherents of the new faith, about half a c. after the flight. The single traditions, as we now possess them, rarely exceed six lines. The dictation is carefully wrought, and the form is that of a dialogue. For the credibility and canonicity of a tradition, it was originally necessary that it should have been *heard* by one truthful witness; but this law was much relaxed in after-time. At the end of the 3d c. (H.), a countless number of individual collections (Mosnad), mostly of an apocryphal character, had been produced by different theologians, but the first who sifted them critically, and without regard to any special theological system, was Bochary (d. 256 H.). His collection contains 7,275 single traditions, 4,000 of which, however, occur twice in the work. Moslim, his pupil, supplemented Bochary with another collection, containing 12,000, again including 4,000 repetitions. Besides these, there are four more "canonical" collections; by Abû Dawûd (d. 275 H.), Tirmidzy (d. 279), Nasây (d. 303), and Mâga (d. 273). The Sunna, as we have it in these collections, contains, broadly speaking, more truth than it is generally supposed to contain, and, critically used, is, besides the Koran, the most authentic source of Islam. A selection from the different collections (both canonical and otherwise), called *Misheat Al Masabih*, has been translated into English by capt. Matthews (Calcutta, 1809). Fragments from Bochary are found in a German translation, by Hammer, in the *Fundgruben des Orients*.

SUNNITES, traditionists or believers in the Sunna (q.v.); the name of the "orthodox" Moslems as opposed to the Shiites (q.v.). They are subdivided into four principal sects, who, though at issue on different minor points, yet are acknowledged by each other to belong to the faithful, and to be capable of salvation, and they each have a special oratory at Mecca. The first of these sects are the Hanefites, founded by Abu Hanifa, who died 150 years after the Hegira. They are emphatically called "the followers of reason," whilst the other three are guided exclusively by tradition. They allow reason to have a principal share in their decisions on legal and other points. To this sect belong chiefly the Turks and Tartars. The second sect are the Malekites, founded by Malek Ibn Âns, who died about 180 H. at Medina. As one of the chief proofs of his real piety and humility, it is recorded that when asked for his decision on 48 questions, he would only decide on 16, freely confessing his ignorance about the others. In Barbary and other parts of Africa, the greatest part of his adherents are found. Mohammed Al Shâfeî, born in Palestine, 150 H., but educated in Mecca, is the founder of the third sect, the Shâfeîtes. He was a great enemy of the scholastic divines, and seems altogether to have been of an original cast of mind. He never swore by God, and always took time to consider whether he should at all answer any given question or hold his peace. The most characteristic saying recorded of him is, "Whosoever pretends to love both the work and the Creator at the same time, is a liar." He is accounted of such importance, that, according to his contemporaries, "he was as the sun to the world, and as health to the body;" and all the relations of the traditions of Mohammed were said to have been asleep until he came and woke them. He appears to have been the first who reduced Moslem jurisprudence into a method, and thus made it, from a number of vague sayings, a science. His followers are now chiefly found in Arabia and Persia. Ahmed Ibn Hanbal founded the fourth sect, the Hanbalites. He was born 164 H., and was a most intimate friend of Shâfeî. His knowledge of the traditions (of which he could repeat no less than a million) was no less famed than was his piety. He taught that the Koran was not created, but everlastingly subsisted in the essence of God; a doctrine for which he was severely punished by the caliph Almotasem. On the day of his death, no less than 20,000 unbelievers (Jews, Christians, and Magians) are said to have embraced the Mohammedan faith. Once very numerous, the Hanbalites now are but very rarely met with out of Arabia. On the differences between the Sunnites and Shiites, see **SHIITES**.

SUN-STROKE (otherwise called *heat apoplexy*, *heat asphyxia*, *coup de soleil*, *erythisis tropicus*, and *insolatio*, the name by which it is officially known in the returns of the registrar-general) is a very fatal affection of the nervous system, which seldom occurs in Great Britain, except in extremely hot summers, but is very common in India and other tropical countries. Our knowledge of the nature of this remarkable disease is almost entirely based upon the accounts which have been given of it by Indian medical officers. It is from their reports that the most satisfactory history of this disease at present published—that, namely, of Dr. Aitken in his *Science and Practice of*

Medicine, 3d ed. 1834—is mainly drawn up. From the accounts given by these observers, it is clear that the symptoms of the disease are liable to be greatly modified in different cases. Mr. Russell, when in charge of the 68th regiment in May, 1834, shortly after its arrival at Madras, with the men in robust health, has given the following account of this disease: "The funeral of a general officer being about to take place, the men were marched out at an early hour in the afternoon, buttoned up in red coats and military stocks, at a season, too, when the hot land winds had just set in, rendering the atmosphere dry and suffocating even under the shelter of a roof, and when the sun's rays were excessively powerful. After having proceeded two or three miles, several men fell down senseless. As many as eight or nine were brought into hospital that evening, and many more on the following day. Three men died—one on the spot, and two within a few hours. The symptoms observed (and they were alike in the three cases), were, first, excessive thirst, and a sense of faintness; then difficulty of breathing, stertor, coma, lividity of the face, and in one whom Mr. Russell examined, contraction of the pupil. The remainder of the cases (in which the attack was slighter, and the power of reaction perhaps greater) rallied; and the attack in them ran on into either an ephemeral or a more continued form of fever." Aitken, *op. cit.* One of the earliest symptoms, noticed by several observers, is the skin becoming rough and zealy, and the perspiration ceasing; the heat of the surface becomes at the same time much increased; the bowels become obstinately constipated. The actual attack, in the various cases described by the Indian surgeons and physicians, came on generally when the men were in their tents, sometimes during the day, but in several cases during the night. The patient had been generally lying down, often seemingly asleep, when the attention of his comrades would be directed to his hurried and heavy breathing, and on attempting to rouse him, he was found to be insensible. The mortality from sun-stroke is about 50 per cent. In the cases that terminate favorably a gradual remission of the symptoms takes place; and when the skin becomes cool and moist, and sleep has been procured (phenomena which usually occur within 36 hours of the attack), the patient may be regarded as out of danger.

The predisposing causes of sun-stroke are (1), an unusually elevated degree of temperature, accompanied by great dryness of the air; (2) The electrical condition of the atmosphere that precedes a thunderstorm; (3) A contaminated atmosphere from overcrowding; (4) All debilitating causes, such as prolonged marches, previous disease, intemperate habits, etc. Death sometimes occurs so suddenly that there is little opportunity for treatment, but the general indications in these cases are—the cold douche, from a height of three or four feet, keeping the surface wet and exposed to a current of air, the exclusion of light as far as possible, and the free employment of stimulants. In less rapidly fatal cases the outer clothing should be removed, and the douche applied, as before, over the head and along the spine. Relaxation of the pupil is the first favorable sign. If the pulse flags the douche must be replaced by the mere application of cold to the head. The hair must be cut as short as possible, and the nape of the neck blistered as speedily as possible. If insensibility recurs after an interval of ten or twelve hours, a blister should be applied to the crown of the head. The extremities and chest should be stimulated with mustard poultices. Immediately after the employment of the douche, a strong purgative injection should be thrown up the lower bowel by means of a long stomach-pump tube (as, for example, a mixture of an ounce and a half each of castor oil and oil of turpentine, and two drams of tincture of asafetida in about half a pint of barley-water). Under no circumstances should there be any abstraction of blood. The preventive measures are of more importance than the treatment; but this is a subject into which we have not space to enter. The advice of the regimental surgeon is too often disregarded by the commanding officer; and the lines which are italicized in Mr. Russell's account of the cases—quoted at the beginning of this article—would seem to contain a well-devised prescription for the induction rather than the prevention of sun-stroke.

SUONADA (inland sea), an inland sea of Japan, which separates the island of Kinsiu and Sikopf from the larger one of Nipon. It is about 250 m. in length from the strait of Simonoseki to Osaka; and sir R. Alcock estimates its greatest breadth at 50 miles. It is studded with innumerable islets and a few rocks. The scenery is picturesque. The prince of Nagato and Soulio having, contrary to treaty stipulations, closed this sea to foreign vessels and fired upon them, the English, French, and Dutch fleet destroyed the forts that barred its entrance (Sept. 5 and 6, 1864), with the loss to the allied squadron of 12 men killed and 60 wounded.

SUPERANNUATION is a retiring allowance granted under an act of 1839, 22 Vict. cap. 26, to all persons not being weekly laborers employed permanently in the civil service of the country. Before the age of 60, retirement can only take place from broken health (or ostensibly so), or from abolition of office; after 60 any person may retire. If the retirement take place before completing ten years' service, a gratuity only is allowed. After ten years, the pension is $\frac{1}{10}$ of the salary at the time of retirement for every year of service, up to $\frac{4}{10}$, which is the maximum allowed, except under very special circumstances, when the treasury may grant larger pensions, never, however, exceeding the salary vacated. Professional persons appointed later in life than the usual age may

have pensions computed with a number of years, not exceeding 20, added to their actual service. On the other hand, the treasury may, for grave demerit, diminish a pension below the scale granted in the act. A person on a pension is liable to recall to a position as good as he vacated up to the age of 60, if in suitable health. A civil servant is defined to be one holding appointment direct from the crown, or under certificate from the civil service commissioners; and his salary must be paid out of the consolidated fund or out of moneys voted by parliament. Weekly laborers are ineligible; but artificers may serve for superannuation, provided they are not paid at the full current market rates of wages. See RETIREMENT.

Superannuation is one of the great boons of the permanent civil service, in which the officials are, as a rule, paid salaries lower than they could earn elsewhere; but to render promotion tolerably certain, retirement at 60 should be, not as now voluntary, but compulsory. At present an official may at his option serve as long as he is capable of attending office; and many actually do die in harness, years after they have become useless.

SUPERCARGO is an important officer in a merchant vessel, charged with the control of all her commercial transactions. The cargo is under his care, and he judges as to its disposal and replacement.

SUPEREROGATION, WORKS OF (Lat. *supererogata*, over and above things required), a class of works which, in the Roman Catholic system, are described as not absolutely required of each individual as conditions to his eternal salvation. Roman Catholics found this definition on the distinction between what they believe to be commanded and what they hold to be only counseled, for an example of which they appeal to the words of our Lord to the young man in Matthew xix. 21, which distinguish one class of works which are necessary in order to "enter into life," and a further class which must only be done if we "would be perfect." Roman Catholics do not profess to recognize in works of supererogation any distinctive essential quality by which they differ, whether in their physical or their moral entity, from other works, and in virtue of which, by their own nature, the individual may found upon them a personal claim to reward. For works of supererogation, as for all supernaturally good works, they hold that the assistance of God's grace is indispensably necessary; and they do not ascribe to them any merit, except that which arises from God's own free and gratuitous promise. In one word, the only distinctive characteristic of a work of supererogation lies in its not being supposed to be prescribed or commanded as absolutely necessary for the salvation of the individual, and its being done for the sake of greater perfection; and the doctrine which teaches the possibility of such works is, according to Catholics, a necessary consequence of the unequal fervor and unequal degrees of holiness which exist even in the class of the virtuous servants of God. A further consequence of this doctrine is that God may accept the superabundant works of one in atonement for the defective service of another; and hence, in the Catholic theory of indulgences (q. v.), along with what they regard as the infinite and inexhaustible treasure of the merits of our Lord, they also regard, although in a degree infinitely inferior, the superabundant merits of the saints as forming part of that "treasure of the church" which is applied in the form of indulgences.

SUPERFETATION, or the circumstance of two distinct conceptions occurring in the same woman at an interval of greater or less duration, so that two fetuses of different ages—the offspring possibly of different parents—may co-exist in the uterus, is a subject of great interest both in a scientific and in a medico-legal point of view. A couple of centuries ago, there was a universal belief in not only the possibility but the comparative frequency of this occurrence. Fifty years ago, it was as universally disbelieved; and now again (owing to the investigations of various inquirers, among whom Dr. Bonnar of Cúpar deserves special mention), we are returning to the belief of our ancestors. The cases described as instances of superfetation may be arranged in three classes; but as will be presently seen, it is only to the cases of the third class that the term superfetation is truly applicable. The *first class* includes the numerous undisputed cases in which two mature children, bearing evidence, from their different colors, that they are the offspring of different parents, are born at the same time. In the slave states of America, it was by no means uncommon for a black woman to bear at the same time a black and a mulatto child—the former being the offspring of her black husband, and the latter of her white lover; and the converse has occasionally occurred—a white woman at the same time bearing a white and a mulatto child. There is no difficulty in accounting for these cases, which are examples of contemporaneous conception rather than true superfetation. The *second class* includes those cases in which a twin has been aborted, leaving its fellow undisturbed in the uterus, to be matured and born in due time, or in which twins have been produced at the same time, one of which was fully formed, while the other was small and apparently premature, from being "blighted" or arrested in its development at an early period. Cases of these kinds are by no means rare; but there is no reason for believing that the infants were conceived at different periods. The *third class* includes the cases in which a *mature* child has been born, and an *immature* fetus, the product of a different conception, has either been left in the womb until its period of maturation, or, if expelled along with the other, has presented no mark of wasting or of arrested development. "In a case of genuine superfetation,"

says Dr. Bonnar, "a woman must bear two (or more) *mature* children, with an interval of weeks or months between the birth of each; or, if she part with the whole contents of the uterus at the first delivery, the difference of the ages of the fetuses, or the mature child and the fetus, as the case may be, must be unmistakable, and there must be the absence of all marks of blight of the latter, so as to leave no doubt that, had it remained in utero, it would have gone on to perfect maturity." Among the cases of superfetation that have been specially discussed by writers on midwifery and medical jurisprudence, are the following: (1) Velpeau quotes from the *Recueil de la Société de Médecine* the case of a woman named "Arles," who, in 1796, gave birth to a child at the full time, and five months afterward to another, which was also thought to be at the full time; (2) Dr. Maton, an eminent London physician, communicated to the college of physicians the case of Mrs. T—, an Italian lady, who was delivered of an apparently healthy and mature male child on Nov. 12, 1807, but which lived only nine days. On Feb. 2, 1808, or 82 days after the birth of the first, she was delivered of a second child, which likewise had every sign of being completely formed and mature. The following case, which, as Dr. Bonnar (in his *Critical Inquiry regarding Superfetation*, Edin. 1865) observes, "has been the principal battle-field of the advocates of superfetation and their opponents," and has given rise to more discussion than any other, is recorded by Dr. Desgrange of Lyon. Madame Villard had a miscarriage at seven months on May 20, 1779. In about a month thereafter she conceived again, and on Jan. 20, 1780, she brought forth a living child. No milk appeared in her breasts, the abdomen did not seem to diminish in size, and other symptoms which normally follow delivery were absent. The two surgeons who were in attendance being naturally puzzled, called in Dr. Desgrange, who declared, in opposition to their views, that there was still a child in the womb; and his opinion was confirmed by her being delivered of a living child on July 6, 1780, 167 days after the first birth. Dr. Bonnar has collected from *The Puerage* a number of cases of probable superfetation occurring in married life. Excluding a very few exceptional cases, he adopts Dr. William Hunter's view, that 210 days, or seven calendar months, is the minimum period of uterine life at which a child should be born in order to be reared, and he assumes that no prolific intercourse can take place until at least fourteen days after the first delivery; and with these axioms, he quotes the following cases: (1) In the Hamilton (lord Mountflorenee) family, a daughter, who was born 182 days after the birth of a son who reached maturity, lived to be married, whose supposed uterine life was not more than 168 days. (2) In the Auckland family, the honorable William Frederick Elliot, who was born 173 days after the birth of a sister (who lived 60 years), survived 28 years; although his assumed uterine life was only 159 days. (3) Lord Cecil J. Gordon, brother to the 10th marquis of Huntly, has a son, Cecil-Crosbie, who was born in January 1850 (only 127 days after the birth of a previous child). This son came to maturity, and his assumed period of gestation was only 113 days. "We cannot conceive," says Dr. Bonnar, "how these three cases can possibly be explained except by the doctrine of superfetation;" and Dr. Taylor (*Principles and Practice of Medical Jurisprudence*, page 849) fully adopts his view. Dr. Duncan believes, from anatomical investigations, that up to the third month of gestation, a second conception may follow the first; and he is of opinion that this will satisfactorily account for all the cases of superfetation on record.

SUPERIOR, in Scotch law, means one who, or whose predecessor, has made a grant of heritable property to a vassal, on condition of the latter paying an annual duty or sum of money, generally called a feu-duty. The superior is said to have the superiority, or *dominium directum*, and the vassal has the feu, or *dominium utile*. In popular language, the superior is a kind of landlord. See FEU.—In England, the word is not used, though in copyhold estates the term "lord" corresponds to it.

SUPERIOR, LAKE, the largest body of fresh water in the world, is the highest and most western of the great lakes lying between West Canada and the United States. It is situated not far from the center of the North American continent. Its general form is nearly semi-lunar, the outer curve being towards the north. Greatest length from e. to w., 355 m.; greatest breadth, 160 m.; area, about 3,200 sq.m.—fully that of Ireland. The surface of the lake is about 600 ft. above the level of the sea, and its mean depth 1000 ft., so that its bottom is 400 ft. below the level of the sea. Its surface has an elevation of about 22 feet above that of lake Huron and lake Michigan. The greater portion of this rise is at the Sault Ste. Marie, a strong rapid about a mile in length, at the commencement of the river St. Mary, which transmits the waters of lake Superior to lake Huron.

Lake Superior, being situated very near the water-shed between Hudson's bay and the Mississippi, receives no rivers of importance, although hundreds of small rivers pour themselves into it. The largest are the St. Louis river, which falls into its western extremity at Pond du Lac, and is about 110 m. long; and the Neebigon river, on the n. side, which, with the lake of the same name, has a length of about 200 miles. One of the branches of the Mississippi in Minnesota approaches to within 20 m. of the western extremity of lake Superior; and a small lake near the head of the Albany river, of which the waters flow to Hudson's bay, is only 4 m. from a bay opposite the State islands on the northern shore, forming a route with little portage, which has long been

used by the Hudson's Bay company, for the conveyance of goods from lake Superior to the northern country.

The promontory Kee-wee-naw, near the middle of the s. side, projects far into the lake. The islands are not numerous, the largest being Isle Royale, 44 m. long.

The country around lake Superior is generally bold and hilly, with the exception of the peninsula lying between it and lake Michigan; but few of the hills rise more than 1000 ft. above the level of the lake, and most of them are far below this height. On the southern shore, 100 m. w. of the Saute Ste. Marie, are the Pictured rocks, cliffs of gray and red sandstone, from 100 to 200 ft. high, in many places presenting fantastic forms, and marked by numerous perpendicular stripes of red and yellow, from ferruginous waters trickling down the face of the rock.

The boundary between the United States and West Canada, starting from the outlet of the lake at the Sault Ste. Marie, sweeps toward the n., so as to include in the United States even the Isle Royale, which is only 13 m. from the British coast, and strikes inland from the mouth of Pigeon or Arrow river, on the n.w. shore.

The only obstacle to navigation between lake Huron and lake Superior is the Sault Ste. Marie, which is overcome by a canal of about a mile in length, with two locks, on the American side. This is, perhaps, the finest canal in the world. The sides and bottom are lined with stone throughout its whole length, the locks are admirably contrived, and the largest ships can pass through it with ease. The trade is increasing so rapidly that a canal on the British side will also be required at no distant day.

The water of lake Superior is remarkable for its coldness, purity, and transparency, although the affluents on both sides are either turbulent or deeply colored by vegetable matter from swamps and forests.

A rise or fall in the level of the water, amounting to several inches in a few hours, is frequently to be observed along the shore, and has been supposed to be due to a regular tide, but is probably caused by the wind. Fresh water being more easily moved by the wind than salt water, great waves arise in lake Superior with wonderful rapidity; and even in summer, large steamers are compelled to take shelter in some bay, or under the lee of an island. Owing to the low temperature of the water, compared with that of the air, in summer, fogs are prevalent, resting on the water at night, and vanishing an hour or two after sunrise.

Lake Superior never freezes over, but the bays are sealed up in winter, and a rim of ice extends to some distance all around the shore.

The rocks around the lake are very ancient, belonging principally to the Laurentian and Huronian systems of the Azoic series, overlaid in some places, especially on the s. side, with patches of the lower Silurian. The prevalent Laurentian rock is orthoclase gneiss. Among the Huronian rocks are greenstones, slates, conglomerates, quartzites, and limestones. The lower Silurian rocks are soft sandstones. There is everywhere much evidence of glacial action.

The Huronian rocks are well stored with useful minerals. The copper and iron mines of the s. side are celebrated for their extent and richness, and there is every reason to think that the mineral resources of the British side are equal to those of the American, although as yet comparatively undeveloped. The richest copper-mines are situated near Kee-wee-naw point. The metal occurs principally native, and sometimes in single masses of great size. One was met with in 1853, which measured about 40 ft. in length, and was calculated to weigh about 400 tons. Native silver is found associated with the native copper, and sometimes intimately mixed with it. A rich vein in an islet in Thunder bay (British side) yielded in 1870-72 silver to the value of \$1,230,000. Gold has been found in small specks at Namainse on the British side. Lead ore occurs in some places. The beds of hematite, or red iron ore, at Marquette, on the s. side, are of wonderful extent. The ore is conveyed by a railway to the harbor, thence by vessels to Cleveland, on lake Erie, and thence by rail to Pittsburg, where it is smelted.

The fisheries of lake Superior deserve notice. The delicious white-fish and the gray trout abound, as well as other kinds of fish. The Canadian legislature passed a law in 1855 to put a stop to the wholesale destruction of them on the spawning grounds.

The shores of lake Superior are frequented by bands of the Ojibbeway tribe of aborigines. They are of very pure blood, retain in a great measure their primitive habits, and many of them are still pagans. They seem incapable of adapting themselves to the settled life of the white man.

The white population of the British shore of lake Superior consist as yet only of the fishermen and explorers who visit the region during summer; and of miners, who extract the silver ore from veins recently discovered on Silver island, near Thunder bay. But on the American shore a number of thriving towns have sprung up. All these towns are connected with mines, little attention being yet paid to agriculture. Marquette, near the eastern end of the lake, is connected by a railway with Green bay, on lake Michigan, and thus with Milwaukee and Chicago. A telegraph line has been established.

SUPERPHOSPHATES. See PHOSPHORUS.

SUPERTONIC, in music, the note which, in the diatonic scale, is next above the tonic or key-note, and forms with it the interval of the second, as D in the key of C major.

SUPPLE JACK, a name given in the southern parts of the United States of America to the *berchemia nobilis*, a twining shrub of the natural order *rhamnaceæ*, which is found as far n. as Virginia. It has oval leaves, small flowers, and violet-colored berries. It abounds in the Dismal Swamp and in similar situations, and ascends to the tops of the highest trees. The genus *berchemia* contains a number of species of twining shrubs, natives of warm climates in different parts of the world. The name Supple Jack is also given in the West Indies and tropical America to *serpentina* (or *serotina*) *fruticosa*, a shrub of the natural order *sapindaceæ*, with a long, flexible, woody stem, which climbs to the tops of the highest trees, and is used for walking-sticks. It has poisonous properties, and is employed for stupefying fish.

SUPPLY, COMMISSIONERS OF, persons appointed by the acts imposing the land-tax in Scotland, to assess, and formerly also to collect, that tax. Their principal duty now is to assess the land-tax, and apportion the valuation according to the provisions of the valuation of lands act, 17 and 18 Vict. c. 19. They are entitled to name a convener, who acts as preses of the meeting, and a clerk with a reasonable salary. The qualification, as recently modified by 17 and 18 Vict. c. 91, consists in the being named as an *ex officio* commissioner of supply in any act of supply; or the being proprietor, or husband of a proprietor, of lands of the yearly value of £100; or the eldest son of a proprietor of lands of the yearly value of £400; and a factor of a proprietor of lands of the yearly value of £800 is empowered to act as commissioner of supply in his absence.

By act 17 and 18 Vict. c. 91, the commissioners of supply of every county, and magistrates of every burgh, must cause a valuation roll to be made up yearly, showing the rents of all lands or heritages in the county or burgh, and the names of the proprietors and tenants; and for this purpose, they are empowered to appoint assessors or assessors. A yearly court is to be held by the commissioners and magistrates, for hearing appeals against the determinations of the assessors, in which three commissioners of supply and two magistrates are to form a quorum, the preses having a casting-vote. See VALUATIONS OF LAND, LAND TAX.

SUPPLY, COMMITTEE OF. The sums granted in parliament to defray the public expenditure for the current year are called *supplies*. All bills authorizing the expenditure of public money must originate in the house of commons, and be based on resolutions moved in a committee of supply, which is always a committee of the whole house. The house having resolved that a supply be granted to her majesty, resolves itself into a committee of supply. The various estimates are submitted to the committee, which has to consider what specific grants are to be voted; and the resolutions of the committee are reported to the house, and adopted or rejected. It belongs to another committee of the house, the "committee of ways and means," to consider how the sums shall be raised which are voted by the committee of supply. See WAYS AND MEANS, PARLIAMENT.

SUPPORTERS, in heraldry, figures placed on each side of an armorial shield, as it were to support it. They seem to have been, in their origin, a purely decorative invention of mediæval seal-engravers, often, however, bearing allusion to the arms or descent of the bearer; but in the course of time, their use came to be regulated by authority, and they were considered indicative that the bearer was the head of a family of eminence or distinction. The most usual supporters are animals, real or fabulous; but men in armor are also frequent, and savages (q.v.), or naked men, often represented with clubs, and wreathed about the head and middle. There are occasionally but rare instances of inanimate supporters. On early seals, a single supporter is not unfrequent, and instances are particularly common of the escheatlon being placed on the breast of an eagle displayed. The common rule, however, has been to have a supporter on each side of the shield. The dexter supporter is very often repeated on the sinister side, but the two supporters are in many cases different; when the bearer represents two different families, it is not unusual for a supporter to be adopted from the achievement of each.

In England, the privilege of bearing supporters as now defined belongs to the sovereign and princes of the blood, peers and peeresses, and the heads of a very few families not of the peerage, whose right is based on an ancient patent, or very early usage. No right is recognized by the college of arms as belonging to the sons of peers bearing courtesy titles. Knights of the garter and knights grand cross of the bath are dignified with supporters, which, however, are not hereditary. Supporters have also been allowed to the principal mercantile companies of London. In Scotland, the use of supporters is somewhat less restricted. The distinction was much less wide than in England between the greater and lesser barons (see MIXED BARONS), and the right to supporters was considered to belong to the latter, so long as the baronial status conferred a right to sit in parliament. The act of 1587, which finally excluded the lesser barons from the Scottish parliament, and established a systematic parliamentary representation, was not held to interfere with this armorial privilege, and it is yet the practice of the Lord Lyon to grant or confirm supporters to the representatives of all minor barons who had full baronial rights prior to that date. A limited number of heads of important families, including the chiefs of the larger Highland clans, apart from considerations of barony, participate in the right to supporters. Lyon is also considered to have it in his power to confer them *ex gratia*, a prerogative which is but sparingly exercised, one of the instances of such departure from strict rule having been in favor of sir Walter Scott. Nova Scotia

baronets as such have no right to supporters, though many of them bear them in respect of the baronial qualification.

The lion and unicorn, familiar in the royal arms of the United Kingdom, were adopted, the former from the achievement of England, the latter from that of Scotland prior to the union of the crowns.

In the more modern heraldry, supporters generally stand either on an escrol, containing the motto, or, more properly, on a carved panel of no definite form, which in Scotland is known by the name of a *compartment*.

SUPPURATION is a morbid process which gives rise to the formation of pus (q.v.), which, as is well known, is one of the commonest products of inflammation. There are two doctrines as to the origin of pus. The opinion universally adopted till very recently was, that it was formed from an excessive exudation of the fluid portions of the blood through the walls of the capillaries; in which exudation, under certain conditions, pus-cells were developed. This view is now rejected for the doctrine of Virchow, the eminent professor of pathology at Berlin, who maintains that pus-cells are generated from the corpuscles of areolar tissue, which he supposes to permeate nearly every portion of the body. Pus, according to Virchow, is a young tissue in which, amid the rapid development of cells, all solid intercellular substance is gradually dissolved. A single cell of areola or connective tissue may, in an extremely short space of time, produce some dozen of pus-cells; but the result is of no service to the body, suppuration being, to use his own words, "a pure process of luxuriation, by means of which superfluous parts are produced, which do not require that degree of consolidation or permanent connection with one another, and with the neighboring parts, which is necessary for the existence of the body." There are two different modes of pus-formation, according as the pus proceeds from epithelium (q.v.) or from connective tissue (see **CELLULAR TISSUE**). When puss is formed from epithelium, it is produced without any considerable loss of substance, and without ulceration; but when it is formed from connective tissue, ulceration must always exist. The mucous membranes vary in their power of forming pus. A mucous membrane, according to Virchow, is the more qualified to produce pus without ulceration the more completely its epithelium is stratified, those with a single layer of epithelium being less adapted for the production of pus. Thus the intestinal mucous membrane scarcely ever produces pus without ulceration; while other mucous membranes, containing several strata of cells, are capable of secreting enormous quantities of this fluid without the slightest ulceration (as, for example, the urethral mucous membrane in gonorrhea).

The above cases of suppuration occur on free or exposed surfaces, and are unaccompanied with loss of tissue. Deep-seated pus-formation takes place only in connective tissue. The first stage of formation consists in an enlargement of the normal cells, and a division and excessive and rapid multiplication of their nuclei. This is soon followed by division of the cells themselves, and their conversion into true pus-cells. If this process takes place beneath a surface which does not participate in the morbid change, or which is capable of resisting it for a time, an *abscess* is formed; whereas, when pus-cells are poured forth from an exposed surface, we have an *ulcer*.

Although suppuration is a morbid process, it often accompanies processes of a beneficial tendency (such as granulation), and frequently takes the place of other far more morbid processes. It further affords a mechanical means of removing foreign bodies, such as thorns, splinters of glass, etc., from soft parts into which they may have been driven; and it is possible (as some pathologists believe) that the formation of abscesses may sometimes serve to eliminate morbid matters from the system.

SUPRALAPSARIAN (Lat. *supra*, before, *lapsus*, the fall), the name given to the school of divines which maintains that God's absolute decree of election and reprobation is antecedent to his foresight of the fall of Adam, and irrespective of it. See **SUBLAPSARIAN**.

SUPRA-RENAL CAPSULES AND THEIR DISEASES. The supra-renal capsules are two small, flattened, glandular bodies of a yellowish color, situated, as their name implies, immediately in front of the upper end of each kidney. In weight they vary from one two drams. They belong to the class of ductless glands, and on making a perpendicular section, each gland is seen (like the kidney) to consist of cortical and medullary substance. The blood-vessels and nerves of the glands are exceedingly numerous. Of late years much attention has been drawn to the diseases of these organs from the observation of the late Dr. Addison (of Guy's hospital), that such cases are frequently associated with the deposition of pigment in the skin, causing it to assume a deep bronze color. The following definition of Addison's disease, or *supra-renal melasma*, or *bronzed skin disease*, embracing all the most important points in its natural history, is given by Dr. Aitken: "A morbid state which establishes itself with extreme insidiousness, whose characteristic features are anæmia, general languor and debility, and extreme prostration, expressed by loss of muscular power, weakness of pulse, remarkable feebleness of the heart's action, breathlessness upon slight exertion, dimness of sight, functional weakness and irritability of the stomach, and a peculiar uniform discoloration of the skin, which becomes of a brownish olive-green hue, like that of a mulatto, occurring in connection with a certain diseased condition of the supra-renal capsules. The progress of the

disease is very slow, extending on an average over one year and a half, but may be prolonged over four or five. The tendency to death is by asthenia, the heart becoming utterly powerless, as if its natural stimulus—the blood—had ceased to act.”—*The Science and Practice of Medicine* (3d. ed. vol. ii. p. 72). The numerous cases recorded by different physicians of all countries since Dr. Addison's original observations were made, show that the connection between *bronzing* of the skin and various morbid states of the supra-renal capsules is a fact beyond all dispute; but the exact relationship and pathological significance of the morbid states thus connected are still open questions. The special morbid changes in the capsules necessary for the production of the symptoms which constitute the disease, are first the deposition of a translucent, softish substance; the degeneration of this to a yellowish-white opaque matter; and afterward a softening into an abscess, or drying up into a chalky mass. In the way of treatment, nothing can be done but attempt to improve the general health by nourishing food, tonics, etc. The literature of this very singular disorder is mainly to be found in various memoirs in the *Guy's Hospital Reports*.

SUPREMACY, ROYAL. The term supremacy is, in politics, chiefly used with regard to authority in matters ecclesiastical. From the time of pope Gelasius (494 A. D.) to the reformation, the pope exercised a very extensive authority, judicial, legislative, and executive, over all the churches of western Europe, somewhat undefined in its limits, varying in different countries and at different periods; which continues to be more or less recognized in all countries whose inhabitants are in communion with the church of Rome. At the English reformation, the papal supremacy was abolished, and act 26 Henry VIII. c. 1, declared the king and his successors to be the “only supreme head on earth of the church of England.” A curious document was at the same time drawn up by the government, in which, to avoid misconception, it was explained that the recognition of this headship of the church implies only that the king should have such power as of right appertaineth to a king by the law of God, and that he should not take any spiritual power from spiritual ministers, or pretend to “take any power from the successors of the apostles that was given them by God.” In 1535, the same year in which this act was passed, John Fisher, bishop of Rochester, sir Thomas More, and others, were beheaded for denying the king's supremacy; and in 1578, John Nelson, a priest, and Sherwood, a young layman, suffered the punishment of death for the same offense. The assumption by Henry VIII. of the title of “head of the church,” notwithstanding the explanation alluded to, was much commented on; and on the accession of Elizabeth, it was thought prudent, while again claiming the supremacy in all causes, as well ecclesiastical as civil, to keep that designation in the background. By successive statutes, the oath of supremacy was appointed to be taken by the holders of public offices along with the oath of allegiance and of abjuration, and these three oaths were consolidated into one by 21 and 22 Vict. c. 48. The subject of oaths was, however, revised by the legislature in 1863 and 1871; and a new short oath of allegiance, in which the royal supremacy in matters ecclesiastical is not in express words specified, was substituted for the oath previously imposed upon members of both houses of parliament. See **ABJURATION** and **OATH**.

SURABAYA, a leading sea-port of Java, and capital of a residency, is situated on the Kedi Mâs mouth of the river Kedirie, near the strait of Madura, the citadel being in $7^{\circ} 4' 30''$ s. lat., and $112^{\circ} 40' 40''$ e. long. The population of the city and suburbs is about 93,000. The European town is on the w. bank, 5 bridges connecting it with the Chinese and Javan quarters on the east. There are 2 Protestant clergymen, a Roman Catholic priest and assistant, 4 government and 6 adventure schools for Christian children. There are regular steamboat services to Samarang, Batavia, and other places. In 1874 the government sugar culture in Surabaya employed 57,114 families, and produced 31,445 tons. The government coffee amounted to 386½ tons. The residency of Surabaya comprises an extensive tract of fertile land in the n.e. of Java, and the island of Madura. On Jan. 1, 1874, the population amounted in all to 1,526,148, including 5,342 Europeans and 10,515 Chinese. Rice, coffee, sugar, indigo, cotton, tobacco, and cocoanuts are extensively cultivated.

SURAKARTA, a residency of Java, s.e. from Samarang, with an area of 2,366 sq. m.: is fertile and well cultivated, producing rice, maize, sugar, coffee, tea, indigo, tobacco, pepper, cacao, vanilla, and tropical fruits. In 1874 4,369½ tons of coffee were produced. Pop. 74,823,560, including 1906 Europeans. The people are proud, and less obedient than in the other residencies, but abjectly submissive to the native emperor, though, in many things connected with his government, he must consult the European resident.

Surakarta, the capital of the empire, and seat of the residency, lies on the left bank of the Solo, in $7^{\circ} 31' 30''$ s. lat., and $110^{\circ} 45' 7''$ e. long. covers a large space, and has a population of over 50,000. Many princes and nobles have their palaces in Surakarta: that of the emperor is of great extent and splendor, 10,000 persons, belonging to, or in the service of the royal family, living within the wall. North-east from the royal park lies the European town, in front of which, surrounded by the parade ground, and commanding the palace, is a square fort, with broad canal and drawbridges at the four curtains, and mounted with 30 pieces of heavy artillery. There is a normal school for training Javanese teachers; a government school, with 80 pupils; and an adventure girls'

school, with 40 pupils. A railway was completed in 1870, from Samarang to Surakarta, by which the produce is easily conveyed to the port of shipment, and an impulse given to trade and agriculture.

SURAT (Sans. *Saurashtra*, good country), a large but declining city of British India, capital of a district of the same name, 150 m. n. of Bombay, and about 17 m. from the mouth of the Tapi, in the gulf of Cambay. It is 6 m. in circumference, and it is surrounded on the landward side by a brick wall. The river at Surat is said to be fordable, although at high tide it can float vessels of 50 tons burden. The English and Portuguese factories, the former now used partly as a lunatic asylum and partly as hospital, are both imposing edifices of great strength and solidity. Surat is said to have contained—but this is probably an exaggeration—800,000 inhabitants at the close of the 18th c., about which time its markets were crowded with the costliest wares, brought by merchants from the remotest countries. Its trade and manufactures, once almost extinct, revived during the American civil war, and it still exports cotton and grain to Bombay. Surat is a place of considerable military strength, and the residence of a British military commandant and other dignitaries. Pop. 71, 107, 149.

Surat was long thought to be one of the most ancient cities of Hindustan, but this opinion is now abandoned, and it is believed to have been a mere fishing-village as late as the 13th century. It first rose into importance as the spot whence the Mohammedans of Hindustan embarked on their religious voyage to Mecca. Surat was sacked in 1512 by the Portuguese soon after their arrival in India. In 1612 an English force arrived here in two vessels, under the command of capt. Best, who defeated the Portuguese, and obtained a *firman* from the Mogul emperor, authorizing the residence of a British minister. The Dutch trade with Surat commenced in 1616, when a Dutch factory was established. A French factory was founded in 1668. In the course of time, the English influence began to predominate. In 1759 the castle and fleet were made over to them; and from the year 1800 the government of the settlement has been entirely vested in their hands.

SURBASE. See PEDESTAL.

SURD. See IRRATIONAL NUMBERS.

SURETY. See GUARANTY.

SURFACE GRUB, the caterpillar of the *great yellow underrring moth* (*triphana pronuba*), a pretty large moth, with the upper wings deep brown or pale tawny, the under wings bright orange with a black border. This moth abounds in hay-fields in Britain at the season of haymaking. The caterpillar, when full grown, is nearly an inch and a half long, pale green with a tinge of brown, dotted with black, three pale lines down the back, and seven black spots on the inside of each of the two outer ones. It often does great mischief to the roots of cabbages and turnips, and also devours the roots of grass.

SURF DUCK, or **SURF SCOTER**, *Oidemia perspicillata*, a species of scoter (q.v.) extremely plentiful on the coasts of Labrador, Hudson's bay, and other very northern parts of America, from which great numbers migrate southward in winter. It is a rare visitant of the coasts of Britain and other parts of Europe. In size it is about equal to the mallard. The plumage is black, except two patches of white on the head and back of the neck. It is never seen on lakes or rivers, but only on the sea-coast. It dives so quickly that it is very difficult to shoot except when on the wing. Its flesh is rank, and has a fishy taste.

SURGEON, ARMY AND NAVY. In the army, surgeon is the grade in which an officer enters the medical department, and from which he is promoted in about 15 years to the rank of surgeon-major. He may be attached to a regiment, or serve with a district hospital; pay and duty being practically the same in either case. The pay rises gradually from £182 10s. to £319 7s. 6d. a year; and the surgeon ranks as a lieutenant for six years, and afterward as a captain. In the medical department of the navy, surgeon is also the junior rank, reckoning for precedence as a sub-lieutenant for six years, and afterward as a lieutenant. The pay varies from £200 15s. a year to £310 5s.

SURGEONS. COLLEGE OF. The present "Royal College of Surgeons of England" dates its origin from the year 1460-61, when Edward IV. "did, at the supplication of the freemen of the mystery of barbers of the city of London using the mystery or faculty of surgery, grant to them that the said mystery, and all the men of the same mystery of the said city, should be one body and perpetual community." In 1500, four masters of surgery were appointed, under the title of "Magistri sive Gubernatores mistere Barbitonorum et Sirurgieorum" (*sic*), and six years after this date the barber-surgeons of Edinburgh were incorporated by a charter from James IV. Although the original charter granted to the company of barbers of London was confirmed by several succeeding kings, many persons practiced surgery independently, and apparently in defiance of the company; and in order to check unqualified persons, it was enacted in the 3d year of Henry VIII. (1511) "that no person within the city of London, or within seven miles of the same, shall take upon him to exercise or occupy as a physician or surgeon except he be first examined, approved, and admitted by the bishop of London, or by the dean of St. Paul's, calling to him four doctors of physic, and for surgery other expert persons in that faculty." Hence arose a company called the surgeons of London. In

the 32d year of Henry VIII. (1540), the company of barbers of London and the company of surgeons of London were united "by the name of the masters or governors of the mystery and commonalty of the barbers and surgeons of London." It was not till the 18th year of George II. (1745) that the surgeons of London were by act of parliament separated from the barbers of London, and made a distinct corporation under the name of "The Master, Governors, and Commonalty of the Art and Science of Surgery of London." In the 40th year of George III. (1800), this company was dissolved, and replaced with their former and additional privileges by "The Royal College of Surgeons of London." A new charter was granted to the college in the 5th year of Victoria (1843), in which it is declared "that it is expedient to create a new class of members, to be called fellows," and "that from henceforth the corporate name or style of the said college shall be THE ROYAL COLLEGE OF SURGEONS OF ENGLAND." Power was given to the council to elect not less than 250, nor more than 300, members of the college to be fellows. These "first fellows" were mainly elected from the London and provincial hospital surgeons. Other fellows might subsequently be elected from the members, "after having complied with such rules and regulations as shall be considered expedient, and after having passed a special examination." Those who are admitted to the fellowship by examination are distinguished in the college calendar by the letters *Ex* being prefixed to their name. By an addition to the charter, obtained in 1852, power was given to the council, subject to certain regulations, to appoint members of 15 years' standing to the fellowship without examination. The college was likewise empowered to test the fitness of persons to practice midwifery and to grant certificates of such fitness; and in 1859 it was similarly authorized to test the fitness of persons to practice as dentists, and to grant certificates of such fitness.

The government of the college is vested in a council of twenty-four persons, including one president and two vice-presidents; and none but fellows of 14 years' standing are eligible as members of council. Three members of council go out annually by rotation, and the vacancies are filled up on the first Thursday of July. There is a board and a court of examiners, each consisting of ten members, including a chairman at the former, and a president at the latter; and as the examiners, who receive large emoluments (the fees to the court of examiners for the professional examination of members for the year ending June 24, 1878, were £10,110 15s.), are elected by the council, whose remuneration is slight, a position in the council is eagerly sought for as a stepping stone to an examinership. Besides the court of examiners, there are special boards of examiners in midwifery, in dental surgery, and in classics, mathematics, and French for the preliminary membership and fellowship examination. There are four professorships in connection with the college—viz., that of human anatomy and surgery, the Hunterian professorship of comparative anatomy and physiology, the chair of surgery and pathology, and that of dermatology. A Hunterian orator is appointed every second year. The college sends a representative to the general council of education and registration. A candidate for the membership of the college is required to pass a preliminary examination in the usual branches of a liberal education. The fee for the anatomical examination is £3, 5s., and that for the surgical, or pass-examination, is £16, 15s., making a total of £22. The fellowship fee is an additional 10 guineas. For details, see the *Calendar of the Royal College of Surgeons of England*.

The museum of the college of surgeons is incomparably the finest museum of its kind in the United Kingdom. The Hunterian collection (see HUNTER, JOHN), which forms its basis, was purchased by a parliamentary vote of £15,000, and presented to the college in 1799. The edifice in Lincoln's Inn Fields (the germ of the present pile of buildings) was completed in 1813. The Hunterian collection was estimated to consist of 13,682 specimens; the total number of specimens was recently reckoned at above 40,000. The library contains 38,000 volumes. Both the museum and library are readily accessible to visitors.

SURGEONS OF EDINBURGH. ROYAL COLLEGE OF, was originally an association of those professing "surregerie and barbour-craft," who obtained their first civic charter in 1504, and had it confirmed by James IV. next year. About 1589 began the custom of granting leave to barbers to practice their profession, without admitting them to the full freedom of the incorporation. For a century and a half the members of the craft were sole teachers and almost sole professors of the surgical art in Edinburgh, and contrived to hold their own against the physicians, who, both before and after their incorporation as a royal college in 1681, made efforts to secure authority over the surgeons. In 1637 the surgeons granted the apothecaries a civil status in alliance with themselves; the nominal connection with the barbers was dissolved in 1732. A patent of 1694 settled the relations between the surgeons and the physicians, making amicable terms possible; and in 1778 the surgeons became formally a royal college too. Nevertheless they remained, much against their will, one of the incorporations of Edinburgh, till the act of 1851 dissolved what survived of their civic rights, and set the college free from the galling control of the town council. The college, which in 1879 had more than 410 fellows, sanctions the lectures of a staff of its own members as qualifying for examination candidates for its diploma of licentiate, and appoints a board of examiners. This examination is now usually taken in connection with that for the diploma of the college of physicians.

SURGERY. There can be no rational doubt that surgery (Gr. *cheir*, the hand; *ergon*, work, signifying the manual interference, by means of instruments or otherwise, in cases of bodily injury, as distinguished from the practice of medicine, which denotes the treatment of internal diseases by means of drugs) is as old as man himself. Passing over the very little that is known regarding the state of surgery among the early Egyptians and the Jews, and the skill ascribed to Chiron and other mythical personages among the early Greeks, we may regard the true history of surgery as commencing with Hippocrates, who flourished in the 5th c. B.C. He was acquainted with the ordinary means of counter-irritation, as issues, a kind of moxa, and the actual cautery. He seems to have performed the capital operations with boldness and success; he reduced dislocations and set fractures, but clumsily and cruelly; extracted the fetus with forceps when necessary, and both used and abused the trepan. He did not perform lithotomy, the practice of which seems at that time to have been well known, but to have been confined to a few, who made it their exclusive study. From the time of Hippocrates we may pass over a couple of centuries, when, on the death of Alexander the great, Alexandria became the great school of anatomy, surgery, and medicine. Herophilus and Erasistratus (300 B.C.) were as distinguished for their surgical skill as for their anatomical knowledge. One member of this school, Ammius, invented an instrument by which he broke down stones in the bladder, thus anticipating by about 2,000 years Civiale's discovery of lithotomy. When the great Alexandrian library was destroyed by fire, Rome became the headquarters of science in all its departments. The early Romans of all ranks held surgeons and physicians in abhorrence, and trusted for cures, even in cases of dislocation and fracture, to spells and incantations. The first regular surgeon who settled in Rome was Archagathus (220 B.C.), a student of the Alexandrian school. At first his skill procured for him a high reputation, but the old prejudices soon revived, and he was banished from the Roman capital. The first Roman surgeon of real merit was Celsus, who flourished at the beginning of the Christian era, who improved the mode of performing lithotomy and amputation, described the operation for cataract, and first recommended the application of ligatures to wounded arteries, for the purpose of arresting hemorrhage. His works contain an exact representation of surgical knowledge up to his own time. Aretæus of Cappadocia, who practiced in Rome during the latter half of the 1st c., was the first to employ blisters, using cantharides (as we still do) for that purpose. Rufus of Ephesus, who lived half a century later, first tied an artery which had become aneurismal in consequence of being wounded in venesection. Galen, who practiced in Rome in the latter part of the 2d c., mainly obtained his great reputation by his medical practice. His surgery was confined for the most part to fomentations, ointments, and plasters for external application; to the art of bandaging, and to the employment of complicated machinery in fractures and dislocations. There is little record for several future centuries. Aëtius, in the 6th c., recommended scarification of the legs in dropsy, tried to dissolve urinary calculi by internal remedies, studied the diseases of the eye, and is the first writer who notices the guinea-worm. Paulus Ægineta, in the 7th c., opened internal abscesses by caustics, improved the operation of lithotomy, described several varieties of aneurism, extirpated the breast, performed laryngotomy and tracheotomy, and was the originator of the operation of embryotomy. His sixth book is regarded as the best body of surgical knowledge previous to the revival of letters. Rhazes, an Arabian, who had charge of an hospital at Bagdad, at the end of the 9th c., was the first to describe spina bifida, but he did not understand its real nature; he cauterized the bites of rabid animals, and gave a better account of hernia than any of his predecessors. To Avicenna, who lived a century later, we probably owe the first use of the flexible catheter, and of the instrument now generally known as Hey's saw. Albucasis (died 1122) describes an instrument for the cure of fistula lachrymalis, the removal of tumors by ligatures when the knife is inexpedient, the suture of wounded intestines, the use of the probang in obstruction of the gullet, etc., and is the only ancient writer on surgery who describes the instruments used in each special operation. In 1271 Pitard, an eminent surgeon of his time, laid the foundation of the college of surgeons of Paris. In our own country, Gilbertus Anglicanus, who lived about the beginning of the 14th c., is the first known surgical writer; he was shortly followed by John of Gaddesden, author of the *Rosa Anglica*. In the middle of that century Guy de Chauliac, the first to describe the Cæsarian operation, practiced at Avignon; and contemporary with him was John of Arderne, who is regarded as the first surgeon of his time. During the 15th c. the local application of arsenic for cancer was proposed by Tarantia, a Portuguese surgeon practicing at Montpellier; and lithotomy was removed from the hands of itinerant quacks into the department of pure surgery, by Colot, a surgeon to the French court. Moreover, the college of surgeons dates from this century, having been founded in 1460-61; while at the commencement of the next century (1505) the Edinburgh college was founded. The surgery of the 16th c. may be said to be represented by Ambrose Paré (q.v.). His works, first published in 1535, exerted a most beneficial influence on the profession. Toward the close of this century, Fabricius ab Acquapendente (q.v.), to whom we are indebted for the modern trephine, and for the use of the tube in tracheotomy, published his *Opera Chirurgica*, which passed through 17 editions. Early in the 17th c. (1612), a Scotchman named Lowe published *A Discourse*

on the whole Art of Chirurgery; and about 50 years later Wiseman, who has been appropriately termed "the Paré of England," and "the true father of British surgery," flourished. He was sergeant-surgeon to Charles II., and his surgical works, published in 1676, may still be read with interest. He was the first to dispel the dangerous belief that gun-shot wounds were of a poisoned nature, and had consequently to be treated with the most painful kinds of dressing. Contemporary with him were James Young of Plymouth, who first performed the flap-operation in amputation; Scultetus (a German), the author of *Armentarium Chirurgicum*; frère St. Cosme, commonly known as frère Jacques, a French monk, who considered himself specially commissioned by heaven to cut for stone, and who has the merit of having converted the tearing into a cutting operation; Rau of Leyden, one of the most successful lithotomists of any age, and a pupil of frère Jacques; and Roonhuysen, who divided the sternomastoid muscle for wry-neck, and may thus be regarded as the inventor of tenotomy. The 18th c. produced, in England, White, the originator of excision of joints; Cheselden and Douglas, famous as lithotomists; Percival Pott, John Hunter, and Hey of Leeds; in Scotland, Monro, Benjamin Bell, and John Bell; in Ireland, O'Halloran and Dease; in France, Petit and Desault—the former celebrated for his work on diseases of the bones, and the latter distinguished for his improvements in surgical instruments of various kinds; in Germany, Richter and the illustrious Haller; and in Italy, Lancisi, Morgagni, and Scarpa. Moreover, in this century (1784) the royal college of surgeons in Ireland was founded. Never was surgery so brilliantly represented as during the present century. The London medical schools can point with equal pride to the names of Abernethy, Blizard, Brodie, Astley Cooper, Dalrymple (the oculist), Earle, Guthrie and Nissen (the great military surgeons), Aston Key, Liston, Stanley, Travers, Tyrrell (the oculist), Ware (the oculist), James Wilson, and many other nearly equally celebrated surgeons of an earlier date; and to the more recent ones of Arnott, Bowman, Erichsen, Ferguson, Prescott Hewett, Hilton, Lane, Lawrence, Luke, Paget, Spencer Wells, and a host of others. In Edinburgh were sir Charles Bell, Lizars, Miller, Syme (whose name will ever be associated with a special amputation of the foot, and with the operation for stricture), and Simpson, discoverer of the application of chloroform to surgical practice. Among the most recent innovations and improvements in surgical practice may be mentioned the practice of *antiseptic surgery*, with which the name of Joseph Lister is so worthily associated. The principle of prof. Lister's method consists in the exclusion of septic matter—usually existing in the form of germs, and derived from the atmosphere—from raw or wounded surfaces. Wounds are dressed under *carbolic acid* spray, and with other preparations of this and other antiseptic substances, care being taken in dressing the wound to exclude ordinary atmospheric air. The results of this practice have been on the whole surprising; and recoveries from many serious operations have taken place in remarkably short periods, and with an absence of suppuration and other secondary effects of the inflammatory process. Among the surgical celebrities of Dublin must be mentioned Peile, the inventor of Peile's lithotome and staff; Todd (the father of the late eminent Dr. Todd, of London), who was the first to successfully revive the treatment of aneurism by compression; Colles, the first to describe the fracture known as Colles's fracture of the radius; Carmichael, distinguished for his opposition to the indiscriminate use of mercury in syphilis; Bellingham, and Hutton, whose names are associated with the full development of the revived treatment of aneurism by compression; Cusack, Porter, McDowell, and sir Philip Crampton; Adams (well known for his treatise *On the Diseases of the Joints, and Chronic Rheumatism*), R. W. Smith (celebrated for his researches on fractures and neuroma), and Jacob (the discoverer of the *membrana Jacobi*). It would be impossible to mention a tithe of the names of those who have attained high surgical celebrity in the provinces during the present century. The barons Dupuytren and Larrey, and MM. Amussat, Chassaignac, Civiale, Brasdor, Broca, Desmarre (the oculist), Nelaton, Roux, Siehcl the oculist), Velpéau, etc., have honorably sustained the reputation of French surgery. Beer (the oculist), Chelius, Dieffenbach, Von Gáfe (the oculist), Gurll, Jäger (the oculist), Langenbeck, Stromeyer, and Wützer, constitute but a small portion of the eminent surgeons of Germany. Callisen of Copenhagen, Porta of Pavia, and Perogoff of St. Petersburg, may be taken as the surgical representatives of their respective countries. Among American surgeons, the names of Valentine Mott, the Warrens, Marion Sims, and Gross deserve special notice. To understand what surgery now is, and to trace its recent progress, the reader should study the standard surgical treasures of Erichsen, Ferguson, Miller, and Syme; and the comprehensive and most valuable *System of Surgery*, edited by Mr. Holmes, and contributed to by many of the most eminent authorities on surgery. He will also do well to read Ferguson's *Lectures on Conservative Surgery*, and Syme's *Address on Surgery*, delivered before the members of the British Association in Aug., 1865.

With the increase of knowledge, specialities naturally develop themselves; and such has been the case in surgery. The diseases of the eye, the diseases of the ear, the diseases peculiar to women, the diseases of children, and deformities (the treatment of which is termed orthopedic surgery), more or less separate themselves, at least in large towns, from general surgery, and constitute special departments, of which dentistry may be considered one; as most of the eminent dentists of the present day are regularly educated and qualified surgeons:

It is deserving of record that within recent years nearly all the British universities have commenced to give surgical as well as medical degrees.

For further information on the history of surgery, the reader is referred to the old histories of Le Clerc (Geneva, 1696) and Freind (Lond. 1725), to Moir's *Outlines of the Ancient History of Medicine*, to Sprengel's voluminous *History of Medicine* (in German), and to the admirable "Historical Notice of Surgery" in the late prof. Miller's *Principles of Surgery*, from which we have borrowed many of the details incorporated in this article.

SURICATE, the *Ryzæna capensis*, a carnivorous animal of s. Africa and the cape of Good Hope, sometimes called *zenick*. It belongs to the family *viverridæ*, and is, therefore, allied to the civet (q.v.), genet (q.v.), ichneumon (q.v.), and paradoxurus (q.v.). The generic characteristics are: feet rather long, and toes with robust claws adapted to burrowing habits; tongue furnished with horny *papillæ*; ears small; tail long, slender, and pointed. Dental formula $i \frac{3-3}{3-3}; c \frac{1-1}{1-1}; m \frac{5-5}{5-5} = 36$. The genus *ryzæna* resembles

the ichneumons in the tinting and stripes of the coat; but the legs are longer, there are only four toes on each foot, and the dentition differs in not having small molars immediately behind the canine (II). The *R. capensis* is about 2 ft. long, including the tail; fur, a mixture of brown, white, yellowish, and black. The color of the hair is brown at the bottom, black near the tips, and hoary at the points; those on the back undulated; inside of the legs, yellowish-brown; tail, tufted with black. According to Pennant it is called the *meer-rat* at the Cape. It also resembles the ichneumons in habits, and its urine is very fetid. It eats flesh, preys on mice, and devours quantities of cock-roaches. Sometimes it is domesticated for the purpose of exterminating vermin.

SURINAM. See GUIANA, DUTCH.

SURINAM BARK. See ANDIRA.

SURMOUNTED, in heraldry, a term used to indicate that one charge is to be placed over another of different color or metal, which may respectively be blazoned: Sable, a pile argent surmounted by a chevron gules; and, argent, a cross gules, surmounted by another or.

SURMULLET, *Mullus*, a genus of acanthopteroan fishes of the family *mullidæ*, a small family formerly included in *percidæ*, but distinguished by having two dorsal fins widely separated from one another, the first spinous; and large, easily detached, strongly ciliated scales on the head and body. The genus *mullus* has no teeth on the upper jaw, but a disk of pavement-like teeth on the front of the vomer. Two long barbels hang from the under jaw, or, when not in use, are folded up against it. Only two species are known, both abundant in the Mediterranean, and both found on the British coasts. They very generally receive the name **MULLET**, by which they are confounded with a very different genus. The **STRIPED SURMULLET**, or **STRIPED RED MULLET** (*M. surmuletus*), is sometimes very plentiful on the southern coast of England, but is rarer toward the north. It approaches the shores in summer, and many surmulletts are then taken in mackerel nets; but at other seasons it is only obtained from comparatively deep water by trawl-nets. It sometimes attains, in the Mediterranean, a weight of 6 or 7 pounds, but has never been known much to exceed 3 pounds in the British seas, and is seldom more than 2 pounds in weight. The ancient Romans, who held it in the highest esteem, gave prodigious prices for fish of unusually large size. They kept surmulletts in their *vivaria*; but there the fish did not increase in size. The color is pale pink, with three or four yellow longitudinal stripes; but where any of the scales have been rubbed off, beautiful tints of purple and bright red appear, which takes place also during the struggles of the fish when dying, and the Romans were therefore accustomed to bring surmulletts alive into their banqueting-rooms, that the guests might see them die, and enjoy the brilliant display of color, before eating the fish. The liver was regarded as peculiarly delicious, and was bruised in wine to make a *garum* for the flesh. The surmullet is still regarded as one of the best of fishes.—The **RED SURMULLET**, or **PLAIN RED MULLET** (*M. barbatus*), is very rare on the coasts of Britain. It is a much smaller fish than that already described. Other species of *mullidæ* are found in tropical seas.

SURNAME (either from its being an additional name—Fr. *surnom*, Ital. *sopranome*—or from the practice of writing it over the Christian name, which is to be seen in the court rolls and other ancient muniments), in modern Europe, the family name. The Roman *cognomen* partook somewhat of the same character; but the introduction of the surnames of modern time cannot be traced further back than the latter part of the 10th century. See NAME.

SURPLICE (Lat. *super pellicium*, above the robe of fur), a linen or muslin vestment, worn by clerks of all degrees of orders in the discharge of their public religious offices. It is by some supposed to be derived from the longer and more flowing vestment which, in the Roman Catholic church, is still used in the mass, and is called the "alb;" but in that church the surplice is worn not alone by priests, but by all who have been admitted even to the church tonsure. Its most ordinary use is for the service of the choir, and it is also employed, along with the stole, by priests in the administration of the sacraments, and in preaching. The use of the surplice was strongly objected to by the Calvinistic

and Zwinglian reformers on the continent, and by the Puritans in England, who regarded this vestment as a relic of popery, and made it the subject of vehement denunciations. The argument against it is to be found in Beza, *Tractat. Theolog.*, iii. 29, and its defense in Hooker's *Ecclesiastical Polity*, book v., ch. 29. Ere ritualism became so common in England, no little stir used from time to time to be created by the use of the surplice by the preacher in the pulpit, contrary to the more general practice in the Anglican church. Preaching in the surplice has been associated in the popular mind with a Romanizing tendency, although it is difficult to say on what basis this association rests.

SURREY (Sax. *Suth-ricce*, the s. kingdom), an inland co. in the s. of England, bounded on the n. by Middlesex, and on the e. by Kent. Area, 483,178 acres; pop. '71, 1,091,635. The middle of the county is traversed from w. to e. by a well-marked ridge of the North downs, which rises in Botley hill, above Titsey, to the height of 880 feet. On the n. side of this range, the land slopes gradually to the banks of the Thames, which runs along the northern border; but on the s. side, the descent is rugged and broken, affording pleasing and sometimes romantic scenery. S. of the main range, and about 4 m. s. of Dorking, is Leith hill, 993 ft. high, the most important elevation in this quarter of the country. Stretching along the southern bank of the Thames, and extending over a space about 6 m. in breadth, is a tract which belongs to the London clay formation; further s., and likewise extending from w. to e., there is a tract of plastic clay, varying in breadth from 1 to 5 miles. Chalk, weald-clay, and iron-sand formations occupy the s. of the county. The principal streams are the Mole and Wey, tributaries of the Thames. The soil of the northern half of the county is fertile; in the w. and s.w. the land is, to a great extent, covered with heath. The climate is soft and mild in low-lying districts, and is favorable to the production of corn and grass. More than four-fifths of the entire area are under culture. In the n., in the vicinity of London, there are numerous market-gardens, the produce of which is sent to supply the markets of the metropolis. Hops, wheat, and the ordinary crops are raised. The county contains much wood, and the beauty of the scenery, and the facility of communication with London, have attracted many residents to Surrey, which is consequently studded over with mansions and villas. Manufactures are carried on in Southwark and in the other southern suburbs of London, as well as in Croydon, Guildford, Kingston, and Reigate, which are the principal towns. The county returns four members to the house of commons.

SURREY, HENRY HOWARD, Earl of, 1516-47; b. England; son of the third duke of Norfolk. His youth was spent in France, and at the court of Henry VIII. In 1540 and for some years later, he served in France and gained the title of field marshal; he captured Boulogne, was made its governor, and gained other victories, but was recalled to England after some slight reverses at St. Eleanne. His influence at court was no longer as powerful as in the life of the duke of Richmond, Henry's natural son; charges of treasonable ambition were constantly urged against the duke of Norfolk and Surrey by the Hertford faction; and in 1546 the two were arrested; Norfolk was sent to the Tower, and Surrey was beheaded, 1547. As a poet he was the first to introduce the sonnet and blank verse in English poetry. He wrote many sonnets, amatory verses, and elegies, and an elegant translation of parts of the *Æneid*.

SURROGATE, an officer having jurisdiction over the personal property of decedents, and often a special jurisdiction over their real estate. The surrogate in England was a representative of the bishop in the diocesan courts, which down to 1857 exercised jurisdiction over the probate of wills, and the issue of letters testamentary and of administration, as well as in matters ecclesiastical. As the bishop could not always hold his court in person, he appointed a "substitute," *surrogatus*, to represent him. Such substitutes, originally ecclesiastics, but in later times lawyers, acted as judges in probate matters; and the court of the archbishop of Canterbury held by his surrogate was the principal court in probate, admiralty, and marriage matters. A separate court of probate and divorce was established in 1857. In New Jersey the surrogate is only an inferior officer of the probate court. In New York there is a surrogate's court in each county held by the county judge, unless the county has more than 40,000 inhabitants, in which case a surrogate is elected for 6 years. See PROBATE.

SURTURBRAND, a kind of brown coal (q.v.) found in the north of Iceland, and there used for fuel. It has a great resemblance to the black oak found in bogs. It is capable of being made into tables and other articles of furniture, but is too brittle to be cut into shavings by a plane.

SURRY, a co. in n.w. North Carolina, drained by the Yadkin and the Ararat rivers; traversed in the n.w. by the Blue Ridge; about 510 sq. m.; pop. '80, 15,301—2,067 colored. The surface is hilly and heavily wooded. The soil is fertile in some portions. The principal productions are corn, tobacco, wheat, and live stock. Co. seat, Dobson.

SURRY, a co. in s.e. Virginia, drained by the James river, which bounds it on the n.e., and by the Blackwater river; about 280 sq. m.; pop. '87, 391—4,560 colored. The surface is irregular and heavily wooded. The soil is sandy. The principal productions are corn, peas, and pork. Co. seat Surry Court House.

SURVEYING. Land-surveying may be considered the earliest practical application of the art of geometry or earth measurement, and must have been in some more or less

rude form coeval with agriculture and the division or appropriation of the soil. In Rome, surveying was considered one of the liberal arts, and the measurement of lands was intrusted to public officers who enjoyed certain privileges; and it is probable that the system of measurement practiced by them was very similar to our plane surveying with the chain and cross-staff of the present day, and has been handed down to us through the feudal period. An examination of ancient records and title-deeds will show that both areas and boundary-lines of the different inclosures forming fields, hundreds, town lands, etc., are often laid down with a considerable degree of accuracy.

Land-surveying may be considered under the following heads: (a.) Plane surveying with the chain, and without the aid of angular instruments, except the cross-staff or fixed angle of 90°. (b.) Modern engineering surveying, in which angular instruments are used. (c.) Coast and military surveying. (d.) Trigonometrical surveying (q.v.).

The fundamental rule of every description of land-surveying, from the humble attempt of the village school-master to lay down an irregular garden-plot, to the trigonometrical survey of a large extent of the earth's surface, when the aid of the most refined improvements of modern science is indispensable, is simply to determine three elements of a triangle, and thence to calculate its area.

In plane surveying with the chain, the three sides of a triangle, ABC, are supposed to be accessible, and are carefully measured on the ground, and then laid down or platted to scale on paper, when an accurate figure of the triangle will be obtained, on which the length of the sides can be marked. To get the area, however, it will be necessary to determine the length of the perpendicular line AD, and this is usually done (when possible) on the ground by means of a simple instrument called a cross, which consists of two sights or fine grooves at right angles to each other, and being placed on the line BC (keeping B and C visible in one of the sights), nearly opposite the angle A, is moved gradually till the angle A is intersected by the other sight. The line AB can be also laid down on the drawing, and its length found by scale, and afterward verified on the ground, or it may be at once laid down on the ground by the use of the chain alone. An improved reflecting instrument, called an optical square, is also often used for this purpose. Any boundaries along the lines or sides of the triangle, ABC, can be determined by the use of offsets (q.v.) or insets, as they occur on right and left of line. No matter what the form of the surface to be surveyed may be—polygon, trapezium, or trapezoid—it may thus be determined by a judicious subdivision into triangles; and when the survey is not of a very extended nature or character, and when no serious obstructions exist, chain surveying is both accurate and expeditious, especially if proof or tie-lines are properly introduced, for the purpose of testing the accuracy of the work.

In every description of surveying, it is best to make the original triangle as large as possible, and to work from a whole downward, rather than build up a large triangle by the addition of several small ones. It would be impossible here to lay down rules to meet the many difficulties which arise in the practice of surveying, and indeed the best test of a good surveyor is the ease with which he will overcome local obstructions, which appear almost insurmountable to a novice, or even to a theoretical surveyor with little field practice.

Where buildings or other impediments are found in the measurement of a straight line, they are generally passed by the erection of short perpendiculars sufficient to clear the obstacles, and a line parallel to the original measured as far as they exist, when the original line can be again resumed. Differences of level, occurring in measuring a line where no instruments are used, are generally compensated or allowed for by the judgment of the surveyor.

In registering the dimensions taken on the ground, such as sides of triangles, offsets, intersections of roads, fences, etc., and everything necessary to make a perfect delineation or plan of the surface, surveyors use what is called a field-book, the mode of keeping which varies very much with individual practice. Some surveyors use hand sketches or rough outlines of the form of the ground, and mark the dimensions on them, while others use the ordinary form of field-book, or a combination of the two methods, which perhaps is the best when any difficult complications happen on the ground, such as the frequent occurrence of buildings, enclosures, water, etc., along the line. In the ordinary field-book, the center column, commencing from the bottom, represents the length of any line or side of a triangle; and the figures in the column, the distance at which the offsets to the right or left are taken, or where roads, streams, fences, etc., cross the line, or buildings adjoin the same. We give below the field-book of the assumed survey of the triangle ABC, with the different offsets and insets on its sides, and where roads, fences, streams, etc., cross them, the detail of which can be obtained by subdividing the triangle into smaller internal ones. The figure can thus be

laid down from the book, and its area calculated by the formula $\frac{AB \times CD}{2}$ and the offsets and insets calculated, added, or deducted, by the methods given in OFFSETS.

Ponds, plantations, and enclosures of different kinds may be surveyed with a chain,

The line *ab* may be similarly booked and platted, and any lines intersecting shown.

especially if their form be such that they can be conveniently included in the area of a triangle, the correctness of which, being proved by proper tie-lines, the form, area, etc., may be ascertained by offsets, or rather insets from the sides.

SŪRYA, in Hindu mythology, the god of the sun. His wife is, in later mythology, *Sūryā*, who, in order to escape his embraces, transformed herself into a mare, but nevertheless became the mother by him of the twin *Asvins*, afterward the heavenly physicians. Besides *Sūryā*, he had several other wives, by one of whom, *Sanjā*, he begot Yama, the god of death, and the river Yamunā, or Jumna. By Kuntī, before her marriage with Pān'du (q.v.), he had *Karn'a*, who, therefore, was an elder brother of the Pān'du princes, but in the conflict between the Pān'dus and the Kurus, sided with the latter, and was killed by Arjuna. *Sūrya* became also, by his other progeny, the ancestor of a royal dynasty, called after him *Sūryavans'a*, or the solar race. *Sūrya* is represented with a lotus flower in his hand, on a chariot drawn by seven horses, and conducted by his charioteer Arun'a, the god of the dawn, who is represented without legs.

SURVILLE, MARGUERITE ÉLÉONORE CLOTILDE DE VAILLON-CHALYS DE, 1405-80; is said to be the writer of poems first collected in 1803 by Vanderbourg. Some ascribe them to one of her descendants, the marquis Joseph Étienne de Surville, and others think these poems were written by the publisher Vanderbourg himself.

SUS, a district in Morocco, on the Atlantic ocean, between the Asaka river and the Atlas mountains; about 11,000 sq. m.; pop. about 750,000. The surface is mountainous. The soil is rich. The principal agricultural productions are grapes, figs, olives, almonds, dates, and the ordinary grains and vegetables. Lead and copper are found. The climate is salubrious. The principal city is Tarudant, on the river Sus. The inhabitants of Sus are mostly Arabs or Berbers.

SUSA (Shushan in Daniel, Esther, etc., derived by some from shoshan, a lily), probably the modern Sus or Shush, in lat. 32° 10' n., and long. 48° 26' e., situated between the Chapes or Eulaeus (Ula in Daniel), and the Shapur, anciently the capital of Susiana (the *E'lam* of Scripture, mod. *Khusistan*), and one of the most important cities of the old world. Its foundation is variously ascribed by ancient writers to Darius Hystaspes, or to Memnon, the son of Tithonus; and its name, together with its ground-plan, is traced on Assyrian monuments at the time of Assur Bani Pal, about 660 B.C. At the time of Daniel's vision "at Shushan in the palace," it was under Babylonian dominion, but came, at the time of Cyrus, under Persian rule; and the Achæmenian kings raised it to the dignity of a metropolis of the whole Persian empire, and as such Æschylus, Herodotus, Ctesias, Strabo, etc., speak of it. At the Macedonian conquest it was still at its height, and Alexander is reported to have found in it vast treasures, together with the regalia. On Babylon becoming the principal city of Alexander and his successors, Susa gradually declined, but seems still to have contained enormous wealth at the time of its conquest by Antigonos (315 B.C.). It was once more attacked by Molo in his rebellion against Antiochus the great; and during the Arabian conquest of Persia it held out bravely for a long time, defended by Hormuzan. The ruins of its ancient buildings, the palace described in Esther among them, cover a space of about three miles. The principal existing remains consist of four spacious artificial platforms above 100 ft. high. Traces of a gigantic colonnade were laid bare by Mr. Loftus, with a frontage of 343 ft., and a depth of 244. Cuneiform inscriptions exist, together with many other relics similar to those found at Persepolis (see PERSEPOLIS; compare also CUNEIFORM). The "tomb of Daniel" shown near Susa is a modern Mohammedan building.

SUSA, a city of northern Italy, province of Turin, stands on the right bank of the Dora Riparia, at the foot of the Cottian Alps, 32 m. w. of Turin. It is an episcopal see, and has a cathedral consecrated in 1028, with a baptistery of one single block of green marble. Among its other notable buildings are the episcopal palace, the town-hall, and the Borgo de' Nobili. The surrounding country produces wines, fruits, mulberry-trees, and wood. The road over Mont Cenis, opened in 1810, begins at Susa. Pop. 3,300.

Susa, called by the Romans *Segusio*, is a very ancient city; it was founded by the Celts, and was, in the reign of Augustus, the capital of the Celtic chief Cottius, from whom the Cottian Alps received their name, and during the empire was the starting point for crossing Mont Cenis. A triumphal arch, erected by Cottius in honor of Augustus, still remains.

SUSANNAH, HISTORY OF, *The Judgment of Daniel*, also *Susannah and the Elders*, are the different titles of a well-known story, which forms one of three apocryphal additions to the book of Daniel; the other two being *The Song of the Three Holy Children*, and *The History of Bel and the Dragon* (q.v.). It relates how Susannah, the wife of Joiachim, and daughter of Hilkiah, celebrated alike for her beauty and her virtue, was falsely accused of adultery by certain "lovers," whose advances she had spurned; and how, being condemned to death on their evidence, she was saved by the wise Daniel, who tore the mask from her enemies, and caused them to experience the fate they had designed for her. The question—not a very important one certainly—has been much debated, both in the early and later times of the church, whether or not the story of Susannah is true; and arguments (of various weight) have been adduced to show that the book is a fabrication, a fable, a legend, and a history. The most probable view, perhaps, is that which regards it as a tradition of something that did happen in the life of Daniel, but which has been molded into a moral fiction by the hand of a literary artist. The original is believed to have been Greek and not Hebrew. In most MSS. it precedes the first chapter of the book of Daniel, and so we find it in the old Latin and Arabic versions; but the LXX., the Vulgate, the Complutensian Polyglot, and the Hexaplar Syriac place it at the end of the present book, and reckon it as the 13th chapter.

SUSIANA, an ancient province of Persia, on the Persian gulf; bounded n. by Media, occupying most of the region between the Tigris and the Zagros mountains. The *Elymæi*, supposed to be the Elamites of the Bible, were its earliest inhabitants. The Susii were the dwellers on the plains, and there were many tribes of mountaineers.

SUSPENSION, in music. A note is said to be suspended when it is continued from one chord to another to which it does not properly belong, and to a proper interval of which it must eventually give way. Thus we have here the note G extended from the

first chord into the second, in which it is first suspended, and then resolved into the

chord FACF:  This example is a suspension from above, in which a descent is necessary for its resolution; but a note may also be suspended from below, when it is resolved by an ascent: 

SUSPENSION AND INTERDICT, in Scotch law, is a process by which the suspender, who initiates the proceeding, seeks to stop or interdict some act, or to prevent some encroachment on property or possession, or in general to stay any unlawful proceeding. The first step is to present a note of suspension and interdict to the lord ordinary, who grants *interim* interdict either with or without caution, and orders the note to be answered, or refuses interdict. When the note is answered, the lord ordinary passes or refuses the note, and continues or recalls the interdict as the case may be.

SUSPENSION BRIDGE, a village in w. New York, a port of entry in Niagara co.; pop. '70, 2,276. It is on the Niagara river, nearly opposite the lower rapids, 2 m. below the cataract, at a junction of a branch of the New York Central railroad with the Great Western of Canada, which cross the river on a suspension bridge more than 800 ft. long, and 240 ft. above the water. The first work was done on the bridge in 1852: the first locomotive crossed in 1855. It has 821 ft. span, is 24 ft. wide, and contains 400 tons of iron combined with 600 tons of wood. The railway bridge is 18 ft. above the bridge used for carriages and foot passengers. An important trade with Canada passes through this port. In one year the exports and imports amounted to \$12,649,729, and the duties collected to \$491,785.48. It is the seat of De Veaux college, and contains six churches, several hotels, a newspaper, a stone custom-house and post office. It owes its prosperity largely to the number of tourists attracted by the falls.

SUSPENSION BRIDGES. In these bridges the roadway is suspended from chains passing over piers or towers, and firmly fixed at their extremities. When the roadway is equally loaded over its length, the curve of the chain is a parabola. The weight of the roadway being known, the strain upon the chain, and its requisite strength, are readily determined. For example, in

fig. 1, if A be the center of the bridge, and it be required to find the strain upon the chain at the point B, it is evident that the weight of the roadway between A and B is supported by the chain at B; we have then to find what strain in the direction

FIG. 1.

of the length of the chain will support this vertical load. By the principles of mechanics, if we draw a right-angled triangle BCD, of which the side BC is a tangent to the curve at B, CD is vertical, and BD horizontal; and if the length of CD represent numerically the load on AB, then BC will represent numerically the strain on the chain produced by that load, and BD will be what is called the horizontal component of this strain. This horizontal part of the strain is the same for every part of the curve; it is the total strain on the chain at the center A, and the strain carried over the towers and balanced by the backstays, which are firmly anchored to the ground behind them. In this manner the conditions of strength and stability of a bridge uniformly loaded are easily determined, but when we have a rolling load which is heavy in proportion to the weight of the bridge, as for example a railway train, the case is very different, for when the train only occupies one half of the bridge, the chain will be depressed toward that side, and raised at the center; thus an undulation will be produced in the bridge, which, if the train be moving rapidly, would endanger its stability. Various combinations have been devised to overcome this difficulty. The most simple, and practically the best, is to stiffen the roadway so that the strain of the passing load is distributed over a considerable length of the chain. In this manner large railway bridges have been constructed in America; among them is that over the Niagara above the falls, with three lines of rails on it, of which the span is 822 ft., and the height of the platform above the river, 250 feet; it is supported by four wire cables, each containing 3,640 wires. Trains pass over it at the rate of 10 m. per hour. An ordinary suspension bridge is liable to both vertical and horizontal oscillations, the former taking place when a train or other load is passing over it, and the latter being due to the action of the wind. These oscillations cannot be altogether prevented, but can be so reduced as to be harmless by the use of stays, stretching both from the towers and from points on shore to various parts of the bridge. Suspension bridges are generally used in positions where the span is great, and the rolling loads neither great in proportion to the weight of the bridge itself, nor very rapid in their motion. Many beautiful examples are to be seen in this country; among others, we may instance the Menai bridge, 580 ft. span, and the Clifton bridge, near Bristol, 703 ft. span

SUSPENSION OF ARMS. See TRUCE.

SUSQUEHANNA, an American river, which has its origin in Otsego and Canandaigua lakes, in western New York, and, flowing eastward, receives the rivers Unadilla and Chenango, then, turning south, enters Pennsylvania, where it receives the Pittston, the Tioga, the West Branch, and the Juniata, and empties itself into the Chesapeake bay, at Havre de Grace, Md., 400 m. from its source, and 153 from its junction with the West Branch. It is a shallow, rapid, mountain river, with varied and romantic scenery. A canal follows its course, and great quantities of timber are floated down in the spring freshets. Near the mouth it is famous for water-fowl, especially the canvas-back duck, and has important fisheries.

SUSQUEHANNA, a co. in n.e. Pennsylvania, adjoining New York; drained by the Susquehanna river and several creeks; traversed by the Delaware, Lackawanna and Western, and the Erie railroads; about 850 sq.m.; pop. '80, 40,357—36,743 of American birth, 219 colored. The surface is uneven but not rugged. There are fine dairy and stock-breeding farms; oats, corn, wheat, potatoes, butter, and cattle are staples. Co. seat, Montrose.

SUSRUTA is one of the great medical authorities of ancient India. See *Medicine*, under **SANSKRIT LITERATURE**. His work is called *Ayurveda*, and consists of six books. It was edited by Sri Madhusūdana Gupta, in 2 vols. (Calcutta, 1835-36).

SUSSEX, a co. in s. Delaware, adjoining Maryland, bounded on the e. by the Atlantic ocean and the Delaware river; drained by Indian and Nanticoke rivers, and Mispillion creek; traversed by the Delaware and the Junction and Breakwater railroad; about 950 sq.m.; pop. '80, 36,031—5,698 colored. The surface is level and heavily wooded. The soil is generally fertile. The principal productions are corn, wheat, and cattle. Co. seat, Georgetown.

SUSSEX, the n.e. co. of New Jersey, bordering on New York, separated from Pennsylvania on the w. by the Delaware river; 600 sq.m.; pop. '80, 23,553. The surface is hilly, and the soil very fertile. This county produces the largest amount of butter of any in the state. It contains large deposits of iron, zinc, slate, limestone, and franklinite—a rare mineral. Co. seat, Newton.

SUSSEX, a co. in s.e. Virginia, drained by Stony creek, Nottaway and Blackwater rivers; 420 sq.m.; pop. '80, 10,062—10,032 of American birth, 6,701 colored. It is intersected by the Petersburg and Weldon, and the Atlantic, Mississippi and Ohio railroads. Its surface is hilly and largely covered with forests, which supply the lumber which is the principal source of revenue. The soil is fertile, producing grain, tobacco, and dairy products. Co. seat, Sussex Court House.

SUSSEX (South-Saxons), a maritime co. in the s. of England, bounded on the n. by Surrey and Kent, on the s. by the English channel, and on the w. by Hampshire. Area, 936,911 acres; pop. '71, 417,456. The South downs (see Downs) traverse the county from w. to e., ending about 20 m. e. of Brighton, in the lofty cliff of Beachy head. The northern escarpment of the Downs is precipitous, but leads down to the fertile and richly wooded district of the Weald (see Downs). A remarkably productive tract, from 2 to 7 m. in breadth, extends w. from Brighton along the coast to the Hampshire border; and in the s.e. of the county the rich marsh lands that line the coast, and which are 30,000 acres in extent, make excellent pasture-grounds. Of the Down-land there are about 50,000 acres, covered with a fine, short, and delicate turf, on which the well-known breed of Southdown sheep, to the number of 300,000, are pastured. Of the Weald district, which formerly was covered with dense forests, there are within the county 425,000 acres; a considerable tract has been brought under cultivation. Irrespective of the less productive districts, there are in the county 120,000 acres of rich arable land; 150,000 acres are occupied by woods, which abound chiefly in the Weald, and in the forest ridge in the n.e. of Sussex, where are St. Leonard's forest (10,000 acres), and Ashdown forest (1800 acres). The chief rivers are the Arun, Adur, and Ouse, which have their origin in the n. of the county, and flow s. into the channel. In the s. of Sussex the climate is mild, and several large towns (see BRIGHTON and HASTINGS) are largely resorted to by those who seek health or relaxation. Scaford and Pevensey bays are much frequented by vessels, and the e. portion of the coast is defended by martello towers. The county has for centuries been divided into the six rapes of Lewes, Pevensey, Hastings, Chichester, Arundel, and Bramber. It returns four members to parliament. Capital, Chichester.

SUSTENTATION FUND, a fund provided in the Free church of Scotland for the support of the ministers of the church. The idea of such a fund was probably derived by Dr. Chalmers from the system of the Wesleyan Methodists, and a scheme devised by him was made public before the disruption, so that arrangements had been made, and a small sum already collected, when that event took place. The scheme was afterward carried into operation throughout the whole of Scotland, and continues unmodified to the present time. The members of the church are called upon to contribute, according to their own will and ability, to a common fund; of which, after payment of expenses, payments to a fund for widows and orphans, pensions to retired ministers, etc., an equal division is made among the ministers of the church, with a few exceptions, chiefly in the

case of newly formed congregations. The amount of the fund has gradually increased from £68,704 in 1843-44, to £166,427 in 1877-78, when 776 out of 1075 ministers received an equal dividend of £157, the surplus being divided among the ministers (724) of those charges whose contributions amounted to a certain average sum per member. Congregations are permitted to supplement the stipends of their own ministers, and if able are expected to do so. The supplement in some congregations in towns much exceeds the dividend from the fund; but in many parts of the country, the whole, or almost the whole stipends of the ministers are derived from it. The question had been much discussed, whether an equal dividend ought to be made, or a proportion established between the liberality of a congregation and the amount paid to its minister. The subject of the sustentation fund is of interest, not only to the Free church of Scotland, but to all unendowed churches.

SUTHERLAND, a co. in the extreme n. of Scotland, is bounded on the e. by Caithness and the North sea, on the n. and w. by the Atlantic, and on the s. by Ross and Cromarty. Area, 1,207,188 acres; pop. '71, 23,686, or 12½ per sq. mile. The coast-line is 69 m. in extent; and the shores, rugged on the n. and w., where they are broken by the force of the Atlantic, are comparatively flat on the east. The southern and central regions of Sutherland are the most elevated; and rivers, mostly from the middle of the county, flow e. and s.e. to the North sea, and n., n.w., and w. to the Atlantic. The principal mountain peaks are Ben More in Assynt (3,243 ft.), and Ben Clibrigg (3,158 ft.). The chief rivers are the Oikel and the Shin—which, with other affluents, unite to form Dornoch firth—the Brora, Helmsdale Water, and Naver. Extensive moors, the haunt of herds of red deer, stretch across the county; and the rivers and lakes, the chief of which is loch Shin (q.v.), form numerous low-lying valleys or straths. In the interior and western districts, the climate is cold, and the county is often deluged with continuous rains; but in the eastern districts the climate is mild, and the soil very fertile in all agricultural produce. In 1876 there were 28,346 acres under crops, of which 10,583 acres were under corn, 5,058 acres green crops, 6,691 clover and other artificial grasses, and 6,018 acres permanent pasture. The number of cattle in the same year was 13,057; sheep, 228,503; and swine, 1239. Coal, granites of various colors, marble, limestone, etc., are found. In Nov., 1868, traces of gold were found in a burn in Sutherland. A number of "diggers" were attracted to the district, but the gold found, though of excellent quality, was hardly sufficient to repay their labor. The Highland railway passes through the county. Manufactures are inconsiderable. There are good salmon, herring, and white fishings. Sutherland is well supplied with churches. The schools are well attended, and Gaelic is rapidly giving way to English. Almost the whole of the county belongs to the duke of Sutherland. The present duke is eminent for the zeal with which he has devoted himself to the improvement of Sutherland, spending large sums in the reclamation of land by steam-plows, the construction of railways, etc.

Sutherland receives its name from the Northmen, who frequently descended upon and pillaged it prior to the 12th c., and called it the southern land, as being the limit on the s. of their settlements. The condition of the people of Sutherland before 1811, in which year the county began to be opened up by roads, was miserable. Their sustenance, dependent mostly upon their half-starved flocks, was very precarious, and would have failed them often had not charity administered relief. A former duke of Sutherland effected what are known as the "Sutherland clearances," by compelling such of his tenants as could not support themselves, owing to the unsuitability to agricultural purposes of the districts upon which they dwelt, either to remove to more fertile districts, where they received land at a merely nominal rent, or to emigrate at his expense to Canada.

SUTHERLAND, GEORGE GRANVILLE WILLIAM SUTHERLAND-LEVESON-GOWER, Duke of Sutherland; b. England, 1838; succeeded to the dukedom on the death of his father, the second duke of the name, 1861. His mother, Harriet Elizabeth Georgiana, 1806-68, daughter of the earl of Carlisle, was noted for her beauty and as the patroness of the English anti-slavery society and of other movements of reform and benevolence. The present duke was a member of the house for 10 years before his elevation to the peerage, has immense estates in Sutherlandshire, Staffordshire, Shropshire, and Ross-shire. At the present time (May, 1881), he is on a visit to this country, mainly for the purpose of examining our railroad system.

SUTLEJ, or **SUTLUJ**, an important river in the n.w. of India, the eastmost of the five rivers of the Punjab, rises in the sacred lakes of Manasarovara and Rawan-Irad in Thibet, lat. 30° 45' n. long. 81° 15' east. At its outfall from lake Manasarovara, at between 19,000 and 20,000 ft. above sea-level, it is a rapid torrent 30 ft. broad. It flows n.w. for 150 m., when turning to the s.w. it receives the Spiti or Li, a larger stream than itself. The Spiti is 8,592 ft. above sea-level, when it joins the Sutlej, and the scene of the confluence of the two rivers is sublime in the highest degree. Continuing a s.w. course, the Sutlej breaks through the mountain-rampart of the Himalaya, and after flowing in all about 850 m., in the course of which it is joined by the Beas and the Chenab, it falls into the Indus in lat. about 29° north. Its upper course is supposed to be identical with the Hydruis, and its lower course (in which it is called the Chera) with the Hyphasis of the ancients.

SUTLER, is a vendor of provisions allowed by the quartermaster-general to follow an army in the field, for the purpose of supplying the soldiers with such luxuries as they can afford to purchase. Sutlers are under martial law, accompany the baggage on a march, and are narrowly watched, and severely punished if found guilty of any irregularities toward either the soldiers or inhabitants of the country. In the French army a soldier in each regiment is licensed to act as sutler, and is called *vivandier*. See also **CANTEEN**.

SŪTRA (from the Sanskrit *śū*, to sew, literally, therefore, a thread or string) is, in Sanskrit literature, the technical name of aphoristic rules, and of works consisting of such rules. The importance of the term will be understood from the fact, that the *groundworks* of the whole ritual, grammatical, metrical, and philosophical literature of India are written in such aphorisms, which therefore constitute one of the peculiarities of Hindu authorship. The object of the Sūtras is extreme brevity; and, especially in the oldest works of this class, this brevity is carried to such an excess, that even the most experienced would find it extremely difficult, and sometimes impossible, to understand these aphorisms without the aid of commentaries, which, however, are fortunately never wanting, wherever a work is written in this style. Though there is no positive evidence as to the cause or causes which gave rise to this peculiarity of Hindu composition, the method of teaching in ancient India—an account of which is afforded in some of the oldest works—renders it highly probable that these Sūtras were intended as memorial sentences which the pupil had to learn by heart, in order better to retain the fuller oral explanation which his teacher appended to them. But it is likewise probable that this method of instruction itself originated in the scarcity or awkwardness of the writing material used, and in the necessity, therefore, of economizing this material as much as possible; for that writing was known and practiced at the remotest period of Hindu antiquity, is now placed beyond a doubt, though a startling theory was propounded, some years ago, to the effect that writing was unknown in India, even at the time of the great grammarian Pāṇini. The manner, however, in which, up to this day, the Hindus are in the habit of keeping the leaves of their books together, seems to throw some light on the name given to this aphoristic literature. The leaves—generally narrow, and even at the present time often being dried palm leaves, on which the words are either written with ink or scratched with a style—are piled up, and, according to the length of the leaves, pierced in one or two places, when, through the hole or holes, one or two long *strings* are passed to keep them together. The name of Sūtra was probably, therefore, applied to works, not because they represent a thread or string of rules, but on account of the manner in which these works were rendered fit for practical use; just as in German a volume is called *band*, from its being “bound.” That a habit deeply rooted outlives necessity, is probably also shown by these Sūtra works; for while the oldest works of this class may be called Sūtras by necessity, there are others which convey the suspicion that they merely imitated the Sūtra style after the necessity had passed away, more especially as they do not adhere to the original brevity of the oldest Sūtras; and the Sūtras of the Buddhists (see **PITARA**), conspicuous for their prolixity, could scarcely lay claim to the term, if compared with the Sūtra of the Brahmanical literature.

SUTRO TUNNEL. See **TUNNEL**.

SUTTEE' (an English corruption from the Sanskrit *satī*, a virtuous wife) means the practice which prevailed in India, of a wife burning herself on the funeral pile, either with the body of her husband, or separately, if he died at a distance.

The practice of suttee is based by the orthodox Hindus on the injunctions of their Sāstras, or sacred books, and their can be no doubt that various passages in their Purāṇas (q.v.) and codes of law *countenance* the belief which they entertain of its meritoriousness and efficacy. Thus, the *Brahma-Purāṇa* says: “No other way is known for a virtuous woman after the death of her husband; the separate cremation of her husband would be lost (to all religious intents). If her lord die in another country, let the faithful wife place his sandals on her breast, and, pure, enter the fire. The faithful widow is pronounced no suicide by the recited text of the *ṛigveda*.” Or the code of *Yājñika*: “Learn the power of that widow who, learning that her husband has deceased, and been burned in another region, speedily casts herself into the fire,” etc. Or the code of *Angīras*: “That woman who, on the death of her husband, ascends the same burning pile with him, is exalted to heaven, as equal in virtue to Arundhati (the wife of Vasishtha). She who follows her husband (to another world) shall dwell in a region of joy for so many years as there are hairs on the human body, or 35 millions. As a serpent-catcher forcibly draws a snake from his hole, thus drawing her lord (from a region of torment), she enjoys delight together with him. The woman who follows her husband to the pile expiates the sins of three generations on the paternal and maternal side of that family to which she was given as a virgin. . . . No other effectual duty is known for virtuous women, at any time after the death of their lords, except casting themselves into the same fire. As long as a woman (in her successive transmigrations) shall decline burning herself, like a faithful wife, on the same fire with her deceased lord, so long shall she be not exempted from springing again to life in the body of some female ani-

mal. When their lords have departed at the fated time of attaining heaven, no other way but entering the same fire is known for women whose virtuous conduct and whose thoughts have been devoted to their husbands, and who fear the dangers of separation." See for other quotations, H. T. Colebrooke, *Digest of Hindu Law*, vol. ii. p. 451, ff. (Lond. 1801); and his "Essay on the Duties of a faithful Hindu Widow," reprinted from the *Asiatic Researches*, in his *Miscellaneous Essays*, vol. i. (Lond. 1837). But however emphatically these and similar passages recommend a wife to burn herself together with her deceased husband, it should, in the first place, be observed, that *manu*, who among legislators of ancient India, occupies the foremost rank, contains no words which enjoin, or even would seem to countenance, this cruel practice; and, secondly, that no injunction of any religious work is admitted by the orthodox Hindus as authoritative, unless it can show that it is taken from or based on, the revealed books, the Vedas (see SRUTI). An attempt has of late years been made by rājā Rādhakānt Deb, to show that, in a text belonging to a particular school of the black Yajurveda (see VEDA), there is really a passage which would justify the practice of suttee; but in the controversy which ensued on this subject between him and the late prof. H. H. Wilson, it clearly transpired that the text cited by the learned rājā is of anything but indubitable canonicity; moreover, that there is a verse in the *rigveda* which, if properly read, would enjoin a widow not to burn herself, but, after having attended the funeral ceremonies of her husband, to return to her home, and to fulfill her domestic duties; and it seems, at the same time, that merely from a misreading of a single word of this verse from the *rigveda*, that interpretation arose which ultimately led to a belief and an injunction so disastrous in their results. See H. H. Wilson, "On the supposed Vaidik Authority for the Burning of Hindu Widows, and on the Funeral Ceremonies of the Hindus," reprinted from the *Journal of the Royal Asiatic Society*, vol. xvi., in his works, vol. ii., edited by Dr. Rost (Lond. 1862). That an immense number of widows have fallen victims to this erroneous interpretation of the oldest Vedic text, is but too true. Some fifty years ago, however, the East India company took energetic measures to suppress a practice which it was perfectly justified in looking upon as revolting to all human feelings, and which it would have likewise been entitled to consider as contrary to the spirit of the Vedic religion. This practice may now be said to have been successfully stopped; for though, from habit and superstition, even nowadays cases of suttee occur, they are extremely rare, and all reports agree that the enlightened natives everywhere, except, perhaps, in certain native states, support the action of government to repress this evil of bygone times.

SUTTER, a co. in n. central California; drained by the Sacramento and Feather rivers; traversed by the Oregon division of the Central Pacific railroad; about 680 sq. in.; pop. '80, 5,159—4,201 of American birth. The surface is mostly level prairie, without timber. The soil is fertile. Wheat, barley, wool, wine, and fruits are the principal productions. Co. seat, Yuba Dam.

SUTTER, JOHN AUGUSTUS, 1803-80, b. Baden; an officer in the Swiss service, who emigrated to this country in 1834, and became a trader at Santa Fé. In 1838 he made his way to the Pacific coast, thence to the Sandwich islands, and thence to Alaska, on his voyage from which down the coast, he was wrecked in San Francisco bay in 1839. Obtaining a grant of Mexican land, he established in 1841 a settlement called New Helvetia, where the city of Sacramento now stands. He was governor of the n. district of California under the Mexicans, and alcalde and Indian agent after it passed to the United States. In Feb., 1848, while enlarging his saw-mill race, he discovered gold. The discovery, however, brought him disaster. Gold diggers pre-empted his lands, and besides an annual pension of \$3,000, he received nothing else. He settled in Pennsylvania in 1873.

SUTTON, AMOS, 1798-1854, b. Kent, England; in 1824 became a missionary to India where nearly all his life was spent. He compiled various text books in the Oriya language, and translated the Bible and many tracts into the same tongue. He also published a hymn book and several religious books in English.

SUTURE (Lat. *sutura*, a seam) is a term employed both in anatomy and surgery. In anatomy, it is used to designate the modes of connection between the various bones of the cranium and face. A suture is said to be *serrated*, when it is formed by the union of two edges of bone with projections and indentations (like the edge of a saw) fitting into one another. The coronal, sagittal, and lambdoidal sutures (see SKULL) are of this kind. A suture is termed *squamous*, when it is formed by the overlapping of the beveled (or scale-like) edges of two contiguous bones. There are also the *harmonia* and *schindigh's* sutures, the former being the simple apposition of rough bony surfaces, and the latter being the reception of one bone into a fissure of another.

In surgery, the word suture is employed to designate various modes of sewing up wounds, so as to maintain the opposed surfaces in contact. As it may fall to the lot of any person, on an emergency, to have to sew up a wound, the following general rules, applicable to all forms of suture, should be attended to. In passing the needle, the edges of the wound should be held in contact with the fore-finger and thumb of the left hand; and the needle should penetrate the surface at about an angle of 50° (rather more

than half a right angle), and should, at least, pass through the whole thickness of the skin at each stitch. The distance from the edge of the wound at which each stitch should enter and leave the skin, must vary with the depth of the wound; but there should never be less than the eighth of an inch between the margin of the wound and the entrance or exit of the needle. Sutures should not include vessels, nerves, muscles, or tendons. The line of the thread should cross that of the wound at right angles. For incised wounds on the surface of the body, when the edges can only be transfixed from the cutaneous surface, or when the opposite margins can both be traversed by one plunge, a curved needle (such as a common packing-needle) is most convenient, whereas a strong straight needle is more convenient for the completely free margins of extensive wounds, such as are left after amputation. Various forms of needles are used by surgeons. In the *twisted suture*, as used in the operation for hare-lip, the wound is transfixed by pins, around which, beginning with the uppermost, a thread is twisted.

SUVOROF, ALEXANDER VASSILIVITSII, Count, Prince Italiiski, a Russian field-marshal, and the most famous of Russian generals, was descended from a family of Swedish origin, and was born in Finland, Nov. 13 (O. S.), 1729. His father, who was an officer of the Russian army, and rose, in after times, to the rank of general and senator, enrolled young Suvorof at the age of 13, in the Semenof regiment, where he remained till 1754, when he was promoted to the grade of lieutenant. Suvorof was present in the Russian army engaged in the seven years' war (q.v.), and for distinguished behavior at Kunersdorf, received the grade of colonel. By a constant succession of eminent services in the Polish civil war (1763), in the war against the Turks (1773-74), in suppressing internal disturbances, and in subduing the Tartars of the Kuban (1783), he continued to grow in reputation, and rose to the rank of general. In the Turkish war (1787-92) he was commander-in-chief, for the first time brought the bayonet prominently into use in the Russian army, and decided by it the bloody battle of Kimburn (1787), which would otherwise have been a total rout. At the siege of Otchakof (1788), where he narrowly escaped being made prisoner, the battle of Fokshany (Aug. 1, 1789), which he gained in conjunction with the Austrians, and the decisive victory of Rymnik (Sept. 22, 1789), his headlong bravery, and peculiar system of rapid and repeated attack by overwhelming numbers, secured him complete success. For this last victory, which saved the Austrians under Coburg from annihilation or capture, Suvorof was created, by the emperor Joseph II., a count of the empire, and from his own sovereign received the title of count *Suvorof-Rymnikski*. His last great achievement, and the one which has given a predominant coloring to Suvorof's reputation in western Europe, was the capture of Ismail (q.v.). Suvorof's report of his success was couched in the following terms: "Glory to God and Your Excellency; the town is taken; I am in it." He was then appointed (1791) governor of the newly conquered provinces; was afterward sent (1794) to complete the annihilation of the Polish monarchy, which he effected by repeated victories over the Polish armies, the capture of Praga by storm, and the *repossession* of Warsaw (Nov. 19), where a horrible massacre of the inhabitants took place. The grade of field-marshal, and presents of rare value, rewarded these successes. Under Paul, he fell into disgrace (1798), from his impatience of the emperor's fantastic military regulations, and was deprived of his rank; but being restored through English influence, he commanded the Russian auxiliary army sent to co-operate with the Austrians in Italy. In April, 1799, he reached Verona; compelled Moreau to retire behind the Adda with immense loss, including more than 8,000 prisoners; entered Milan in triumph (April 29); again defeated the French under Macdonald, after a desperate three days' conflict, at the Trebbia (June 17-19), and a third time at Novi (Aug. 15), depriving them of the whole of northern Italy. His campaign in Switzerland, which promised to bring him face to face with Massena, then the best general in Europe, was rendered abortive by the tardiness of the Austrians, and the Russians, in spite of Suvorof's remonstrances, were soon after recalled. His escape from the Schackenthal, where he was hemmed in by the French, is considered by many to be the most brilliant and daring retreat ever executed. While on his return to St. Petersburg, where a brilliant reception was awaiting him, he fell dangerously ill in Lithuania, and though, on his recovery, he found himself a second time in disgrace, he continued his route, and arrived privately in the capital, where he died sixteen days afterward, May 17, 1800. His remains were honored with a magnificent funeral, and the czar Alexander erected a statue to his memory on the Champ-de-Mars. This most extraordinary man had naturally a weak constitution, but rendered it almost invulnerable by exercise, strict temperance, and the regular use of cold baths. His mode of life was of Spartan simplicity, and though the oddity of many of his habits seemed only calculated to encourage ridicule, they, in combination with his paternal care of his men, gave him a powerful hold on the affections of an army at once so ignorant and so thoroughly national in sentiment as the Russian. Suvorof, was inflexible in his resolutions and promises, and of incorruptible fidelity. His skill as a general has often been doubted, on the strength of his favorite remark, that all military tactics could be expressed in three words, *stoupai i bi*, "forward and strike;" but his career shows him to have been possessed of all needful military knowledge—though he hated idle maneuvering—and to have excelled in promptitude and ingenuity of conception, and boldness and rapidity of execution.

SUWAN'NEE, a co. in n. Florida, drained by the Suwannee, which bounds it on the w. and s.w.; intersected by the Jackson, Pensacola and Mobile railroad; about 700 sq. m.; pop. '80, 7,162—7,125 of American birth, 3,140 colored. The surface is mostly level. The soil is sandy. The principal productions are cotton, corn, and sugar. Co. seat, Live Oak.

SUZERAIN (Fr. from Lat. *supremus*), a feudal lord. According to the feudal system, as developed in northern Europe, every owner of allodial (q.v.) lands was compelled to acknowledge himself the vassal of a suzerain and do homage to him for his lands. The term was applied less to the king than to his vassals, who had sub-vassals holding of them.

SVENIGOROD'KA, a t. of Russia, in the government of Kiev, 150 m. s. from Kiev, on an affluent of the Southern Bug. Pop. '67, 11,201.

SWABIA, **SWABIA** (Ger. *Schwaben*), or **SUEVIA**, an ancient duchy, in the s.w. of Germany, so named from a horde of Suevi, who spread over it in the 5th c., and amalgamated with the Alemanni, its previous inhabitants. It existed as a great duchy of the Frank empire till the 8th c., when Alsace and Rhetia were separated from it, and the remainder, retaining its name of Swabia, was thenceforth governed by *nuntii camere*, or royal delegates, one of whom having, in 915, usurped the title of duke of Alemannia, was condemned by the German diet and decapitated in 917. Swabia at this time was bounded on the w. and s. by the Rhine, on the e. by the Lech (which separated it from Bavaria) and Franconia, n. by the palatinate of the Rhine and Franconia, and contained about 13,000 English sq. miles. In 918, however, Swabia was acknowledged as a ducal fief of the empire; and, after changing hands several times, was (1080) bestowed upon count Frederick of Hohenstaufen (q.v.), the founder of the illustrious house of this name, also known as the house of Swabia. Under the rule of this prince and his successors, Swabia became the most rich, civilized, and powerful country of Germany, and the ducal court was the resort of the minnesingers (q.v.); but the wars of the Guelphs and Ghibellines, and the quarrel with the French respecting Naples, put an end to the dynasty in 1268. The ducal vassals in Swabia rendered themselves almost independent, and professed to acknowledge no lord but the emperor. During these dissensions arose the lordships of Württemberg and Baden, with numerous lesser states, holding direct of the crown, and opposed to them the cities, which strove also for an equal independence, and at last, in reward of important service, obtained in 1347 great additional privileges. A number of them united to make common cause against the neighboring feudal lords in 1376 (known as the *First Swabian League*); an opposite league was formed between Württemberg, Baden, and 17 towns, in 1405, called the league of Marbach; and both took part in the war of Swiss independence, the former in support of the Swiss, the latter of the Austrians. At last the towns, which had been rapidly increasing in wealth and power, decided at Ulm, in 1449, to form a standing army and a permanent military commission for the forcible preservation, if necessary, of peace and order; and the count of Württemberg, the most powerful of the opposite party, having joined them, was appointed military chief of the league, which ultimately grew up into the *Great Swabian League*, and exercised both administrative and judicial authority over the whole country, effectively repressing feudal quarrels. In 1512 Swabia became one of the ten circles into which Germany was now divided, received its complete organization in 1563, and retained it almost without change till the dissolution of the empire in 1803. But during this period the wars of the towns with Württemberg, the peasants' war, of which Swabia was one of the foci, the thirty years' war, and those between France and the empire, destroyed the democratic constitution of the towns, and with it their energy, and then their prosperity disappeared, leaving now no relic which could suggest their former great political importance.

SWAIN, a co. in w. North Carolina, adjoining Tennessee; drained by the Little Tennessee river; bounded on the n. by the Great Smoky mountains; about 500 sq. m.; pop. '80, 3,785—549 colored. The surface is even and well wooded. The soil is only partly fertile. The principal productions are corn, tobacco, and pork. Co. seat, Charleston.

SWAIN, CHARLES, 1803-74; b. Manchester, England; called the "Manchester poet;" for 14 years employed in the dyeing establishment of his uncle, afterward became an engraver. While connected with the mill he began to write for magazines and annuals. He published various poems and sketches, some of which were translated into German and French. *Dryburgh Abbey*, an elegy on sir Walter Scott, was written in 1832; new ed. 1898. An edition of his poems, with a portrait, and an introduction by Charles Card Smith, appeared in 1857. Wordsworth, Southey, and James Montgomery were among his friends. In 1857 he received a civil-list pension of £50 per annum.

SWAINSON, WILLIAM, b. England, 1789; served in the British army 1807-15. He studied natural history; went to South America in 1815, and afterward settled in London. He was at one time attorney-general of Tasmania, whither he had emigrated in 1841. He began the publication of *Zoological Illustrations* in 1820, and *Exotic Conchology* in 1821. Among his many works are *Naturalist's Guide* (1822); a number of natural history volumes in Lardner's *Cabinet Cyclopædia*. He was living in 1879.

SWALE. See YORKSHIRE.

SWALLOW. *Hirundo*, a Linnæan genus of birds of the order *insessores*, and tribe *fissirostres*, now divided into a number of genera, which form the family *hirundinidæ*. This family consists of birds which prey on insects, catching them in the air, and have great powers of flight, now soaring to a great height, now skimming near the surface of the ground or of the water, and wheeling with great rapidity. The bill is short and weak, very broad at the base, so that the gape is wide; the wings are very long, pointed, and more or less sickle-shaped when expanded; the legs are short and weak, and in some—the swifts (q.v.)—more so than those of any other birds. The tail is generally forked. The plumage is close and glossy. The species are very numerous, and widely diffused, being found in almost all countries. Such of them as occur in the colder parts of the world are summer birds of passage, migrating to warmer regions when winter approaches and insects disappear. The family is divided into two groups, *swifts*, which have remarkably long and curved wings, very small weak legs, and short toes, the hinder toe generally directed forward, and *swallows*—some of which are also called *martins*—having wings not quite so long nor so much curved, rather stronger legs, and longer toes, three before and one behind. The COMMON SWALLOW, or CHIMNEY SWALLOW (*hirundo rustica*), exhibits a character common to many other species, in the very long and deeply-forked tail, the two lateral feathers of which far exceed the others in length. The plumage is very beautiful, the upper parts and a band across the breast glossy bluish black, the forehead and throat chestnut, the lower parts white, and a patch of white on the inner web of each of the tail-feathers except the two middle ones. The whole length of the bird is about 8½ in., of which the outer tail-feathers make 5 inches. The nest is made of mud or clay, formed into little pellets and stuck together, along with straw and bents, and lined with feathers. It is open and cup-shaped, and is generally placed in a situation where it is sheltered from wind and rain, as a few feet down an unused chimney, under the roof of an open shed, or in any unoccupied building to which access can be obtained. Two broods are produced in a year. The migration of this and other British species of swallow, now recognized by all naturalists as an unquestionable fact, was formerly the subject of much dispute, and swallows were supposed by many to become torpid in winter, although it was difficult to imagine that if so they should not frequently be found in that state. The geographical range of these species extends over great part of Europe, Asia, and Africa.—The WINDOW SWALLOW, or HOUSE-MARTIN (*H. urbica*, or *chulidon urbica*), is another very common British species, glossy black above, white below, and on the rump; the feet covered with short downy white feathers, which is not the case in the chimney swallow; the tail long, but its outer feathers not remarkably so. The nest is built of mud or clay, like that of the chimney swallow, but is hemispherical, with the entrance on the side, and is attached to a rock, or, very frequently, to the wall of a house, under the eaves or in the upper angle of a window, to the annoyance of housekeepers who prefer the cleanness of their windows to the lively twitter of the birds, and the opportunity of watching their process of nest-building and their care of their young. House-martins congregate in great numbers, as chimney swallows also do before their autumnal migration, and disappear all at once. The house-martin is among the birds of Lapland and Iceland. The only other common British species of swallow is the SAND-MARTIN (*H. riparia*), smaller than either of the preceding, the toes naked, the tail moderately forked, the plumage brown on the upper parts and across the breast, the under parts white. It makes its nest on sandy river-banks, the sides of sand-pits, and other such situations, excavating a gallery of 18 in. or 2 ft., sometimes 3 or even 5 ft. in length, and more or less tortuous, in the extremity of which some soft material is placed for the reception of the eggs. This wonderful excavation is accomplished entirely by the bill of the bird. The floor slopes a little upward from the entrance, so that the lodgment of rain is prevented. The sand-martin is more local than the other British swallows; but it is distributed over most parts of Europe, Asia, Africa, and North America.—The PURPLE SWALLOW, or PURPLE MARTIN (*H. purpurea*), is a North American species, which has in a few instances been known to visit the British islands. The general color, both of the upper and under parts, is shining purplish blue; the wings and tail black. It abounds in North America, and is a universal favorite in the northern parts, being hailed as the harbinger of spring, and frequenting even the streets of towns. It is a very general practice to place boxes near houses for the martins to make their nests in, which are very artificial, consisting merely of dried grass, leaves, moss, feathers, and the like. Boxes nailed to trees are also readily occupied by the RUFOUS-BELLIED SWALLOW (*H. erythrogaster*), another North American species. But this species which very nearly resembles the chimney swallow of Britain, makes a nest of mud and fine hay, in the form of the half of an inverted cone, with an extension at the top for one of the parent birds to sit in occasionally. The REPUBLICAN SWALLOW, or CLIFF SWALLOW (*H. fulva*), of North America, makes a nest of mud, in form somewhat like a Florence flask, which it attaches to a rock or to the wall of a house. Hundreds sometimes build their nests in close proximity. The FAIRY MARTIN (*H. ariel*), a small Australian species, also builds a flask-shaped nest, with the mouth below, attaching it to a rock, or to the wall of a house, and numerous nests are often built close together.—Some of the swallows of tropical countries are much smaller than any of the European species.—The East Indian

swallows which make the edible nests (q.v.), belong to the section of the family to which the name swift is given.

SWALLOWING. THE ACT OF, is accomplished by a set of associated movements which have been divided by physiologists into three stages. In the first stage, the food having been previously duly reduced to a pulp by trituration and insalivation, is carried back by the contraction of various muscles until it has passed the anterior palatine arch. See PALATE. So far, the movements are purely voluntary. The second stage now commences, during which the entrance of food into the nasal cavities and larynx is most carefully guarded against by certain reflex (involuntary) actions, which have been only clearly recognized since the introduction of the use of the laryngoscope during the last few years. The tongue is carried further backward, the larynx rises so as to be covered by the epiglottis, which is depressed and lies horizontally, so that its upper border touches the posterior wall of the pharynx. Coincident with these movements, the sides of the posterior palatine arch contract by muscular action, and approach each other like a pair of curtains, so as almost to close the passages from the fauces into the posterior nostrils; the closure being completed by the uvula. A sort of inclined plane is thus formed, and the morsel slips downward and backward into the pharynx, which is raised to receive it. Very little, if any, voluntary action is here exerted. The third stage—the propulsion of the food down the œsophagus—then commences, and this process is effected in the upper part by means of the constrictor muscles of the pharynx, and in the lower, by the muscular coat of the œsophagus itself. At the point where the latter enters the stomach, there is a sort of a sphincter muscle which is usually closed, but which opens when sufficient pressure is made on it by accumulated food, closing again when this has passed. See Carpenter's *Principles of Human Physiology*.

SWALLOW-WORT. See ASCLEPIAS.

SWAMMERDAM, JAN, a distinguished naturalist, was b. at Amsterdam, Feb. 12, 1637. Swammerdam, almost from his boyhood, showed the greatest eagerness in the study of natural history. Having entered upon the study of medicine, he particularly occupied himself with anatomy, and continued unremittingly to collect insects, to investigate their metamorphoses and habits, and, by the aid of the microscope, to examine their anatomic structure. He took his degree of doctor of physic at Leyden in 1657, and entered upon the practice of his profession, which his bad health, however, soon compelled him to relinquish. He continued to be chiefly engrossed with anatomy and entomology. His treatise on bees appeared in 1673; a treatise on ephemeræ in 1675. It is impossible, however, for us to enumerate his many publications, all of which were first published in Dutch, and afterward translated into Latin, and many of them into English, French, and German. Swammerdam's discoveries were very numerous, both in human and comparative anatomy. His skill in using the microscope was very great, and his manipulation of the most minute subjects extremely dexterous. He succeeded in giving distinctness to the forms of very minute viscera, by inflating them with air; a method of his own invention. It is melancholy to add, that Swammerdam, who had always displayed strong religious feelings, and expressed them in his writings, was at last carried away by the fanatical extravagances of Antoinette Bourignon (q.v.), began to think all his former pursuits sinful, and relinquished them for a visionary religious life of mere meditation and devotion. His health rapidly declined, and he died at Amsterdam, Feb. 17, 1680. No man of his time contributed more than Swammerdam to the progress of natural history and physiology. He was the inventor of the method of making anatomical preparations by injecting the blood-vessels with wax, and also of the method of making dry preparations of the hollow organs, now generally employed.

SWAN, *Cygnus*, a genus of birds of the duck (q.v.) family (*anatida*), constituting a very distinct section of the family. They have a bill about as long as the head, of equal breadth throughout, higher than wide at the base, with a soft cere, the nostrils placed about the middle; the neck very long, arched, and with 23 vertebra; the front toe fully webbed, the hind toe without membrane; the keel of the breast-bone very large; the intestines very long, and with very long cæca. They feed chiefly on vegetable substances, as the seeds and roots of aquatic plants, but also on fish-spawn, of which they are great destroyers. They are the largest of the *anatida*. They have a hissing note like geese, which they emit when offended, and strike with their wings in attack or defense. The common notion, that a stroke of a swan's wing is sufficient to break a man's leg, is exaggerated. The COMMON SWAN, MUTE SWAN, or TAME SWAN (*C. olor*), is about 5 ft. in entire length, and weighs about 30 lbs. It is known to live for at least 50 years. The male is larger than the female. The adults of both sexes are pure white, with a reddish bill; the young (cygnets) have a dark bluish-gray plumage, and lead-colored bill. The bill is surmounted by a black knob at the base of the upper mandible, and has a black nail at its tip. In its wild state, this species is found in the eastern parts of Europe and in Asia; in a half-domesticated state it has long been a common ornament of ponds, lakes, and rivers in all parts of Europe. It is an extremely beautiful bird when seen swimming, with wings partially elevated, as if to catch the wind, and finely curving neck. The ancients called the swan the bird of Apollo or of Orpheus, and ascribed to it remarkable musical powers, which it was supposed to exercise particularly when its death approached. It has, in reality, a soft low voice, plaintive, and

with little variety, which is to be heard chiefly when it is moving about with its young. The nest of the swan is a large mass of reeds and rushes, near the edge of the water, an islet being generally preferred. From 5 to 7 large eggs are laid, of a dull greenish-white color. The female swan sometimes swims about with the unfledged young on her back; and the young continue with their parents until the next spring. The swan is now seldom used in Britain as an article of food, but in former times it was served up at every great feast, and old books are very particular in directions how to roast it and to prepare proper gravy.—The POLISH SWAN (*C. immutabilis*), of which flocks have occasionally been seen in Britain in winter, differs from the common swan in its orange-colored bill, in the smaller tubercle at its base, and in the shape and position of the nostrils. The young are also white, like the adults. It belongs chiefly to the north-eastern parts of Europe. Many naturalists regard it as the true wild state of the common swan.—The WHISTLING SWAN, ELK SWAN, or HOOPER (*C. ferus*), abounds in the northern parts of Europe and Asia. Flocks frequently visit Britain in severe winters, and their migrations extend as far s. as Barbary. A few breed in the Orkney islands, but the greater number in more northern regions. The size is about equal to that of the common swan, and the color is similar, but the bill is more slender, is destitute of knob, and is black at the tip, and yellow at the base. This bird is frequently brought to the London market. The names hooper and whistling swan are derived from the voice. The anatomical differences between this species and the common swan are more considerable than the external, particularly in the double keel of the breast-bone forming a cavity which receives a long curvature of the wind-pipe.—BEWICK'S SWAN (*C. Bewickii*), another native of northern Europe, is more rare in Britain, but flocks are sometimes seen. It is about one-third smaller than the whistling swan.—The AMERICAN SWAN (*C. Americanus*) nearly resembles Bewick's swan. It breeds in the northern parts of North America, and its winter migrations only extend to North Carolina.—The TRUMPETER SWAN (*C. buccinator*) is another American species, breeding chiefly within the Arctic circle, but of which large flocks may be seen in winter as far s. as Texas. It is rather smaller than the common swan.—The ancients spoke of a black swan proverbially as a thing of which the existence was not to be supposed, but Australia produces a BLACK SWAN (*C. atratus*), rather smaller than the common swan, the plumage deep black, except the primaries of the wings, which are white. The bill is blood-red. It has been introduced into Britain, and breeds freely. It is very abundant in some parts of Australia.—The BLACK-NECKED SWAN (*C. nigricollis*) is a South American species, as is the DUCK-BILLED SWAN (*C. anatoides*), the smallest of all the species, white, with black-tipped primaries, common about the strait of Magellan. It is a curious circumstance that the black color appears more or less in all the species of the southern hemisphere, and in them alone, except in the approach to it made in cygnets.

Swans, according to the law of England, are birds royal. When they are found in a partially wild state, on the sea and navigable rivers, they are presumed to belong to the crown, and this is one of the prerogatives of the crown, though it may be delegated to a subject. The royal birds generally have a mark on them, and the king's swan-herd once was an important person. A subject is not entitled to have a swan-mark unless he has a qualification of land, and has a grant from the crown, or prescriptive use. But any person may have swans in his grounds in a tame state, and then he has a property in them. Whoever steals or destroys swans' eggs, forfeits 5s. for every egg, and whoever steals a marked swan of the crown, or a tame swan, commits felony. In Scotland, there is some trace of the bird having been once treated with royal honors, but latterly they have been in the category of other tame birds.

SWAN, JAMES, 1754-1831; b. Scotland; came to this country when a boy and engaged in business in Boston. He took part in the popular agitation leading to the revolution, was one of the Boston "tea party," and aide to Warren at Bunker Hill. He afterward served as member of the Massachusetts legislature and adjt. gen. of the state. After the war he made a large fortune in Paris, and, 1795-98, visited this country and spent money profusely. In 1815, then being in Europe, he was arrested on a civil suit, and, refusing to settle, lived for 15 years in Ste. Pelagie prison, Paris, in the most magnificent style. He published a number of pamphlets on such subjects as the slave trade (1772), fisheries, the commerce of France and the United States, agriculture, and manufactures.

SWANN, THOMAS, b. Va.; educated at the university of Virginia; afterward studied law at Washington, and in 1834 settled in Baltimore, where the greater part of his life was spent. He was president of the Baltimore and Ohio railroad, 1847-53, and was connected with other railroads. In 1858 he was elected mayor of Baltimore. He warmly supported the union against the rebellion, and in 1864 was chosen governor of the state. In 1868 he was elected to congress and served ten years.

SWAN'S SEA (Welsh, *Abertawy*), a market t., municipal and parliamentary borough, and sea-port of the county of Glamorgan, South Wales, stands on the right bank and at the mouth of the Tawe, 60 m. w.n.w. of Bristol. The harbor is formed by means of piers of masonry projecting from either side of the mouth of the Tawe into Swansea bay, a wide inlet of the Bristol channel. The vast resources of the coal-field in the midst of which the town is situated began to be explored and turned to commercial

account about the year 1830; and since that time the progress of Swansea has been so rapid that it is now the most important town in South Wales. The houses and public edifices and institutions are of recent erection. A good public hall was erected in 1864, and a spacious and well arranged infirmary in 1867. Smelting and refining copper is the staple trade of the town, and the chief source of its prosperity. The coal obtained in the vicinity is peculiarly adapted for smelting purposes, and great quantities of ore are brought hither to be smelted, not only from the copper-mines of Britain, but from Cuba and the west coast of South America. In the immediate vicinity of the town, there are smelting-works, in which about 185,800 tons of copper, copper ores, silver ores, and zinc ores (equal in value to about £4,000,000) are smelted annually. Of the whole amount of copper manufactured in Great Britain, seven-eighths are smelted at Swansea and in its immediate vicinity. In 1859, a large floating dock, 13 acres in extent, was opened by the side of the harbor. Its north side is lined with warehouses for the shipment of coals which are brought to the wharfs by railway. An excellent system of water-works was completed in 1868 at a cost of upward of £70 000. Patent fuel, composed of a mixture of culm and tar, and compressed into the shape of bricks, is an important article of manufacture and trade. There are extensive potteries, and tin, silver, and china works, breweries, rope-walks, and tanneries. In 1877, 5,075 vessels, of 704,914 tons, entered the port, and 6,857, of 975,079 tons, cleared. There are abundant means of communication landward by canals and railways. Pop. 1851, of municipal and parliamentary limits, 31,461; 1861, 41,609; 1871, of mun. bor., 51,702; of parl. bor., 56,995. Of the old castle of Swansea, the ruined remains are used as a military store. Swansea unites with Aberavon, Kenfigg, Loughor, and Neath in sending a member to the house of commons.

SWARGA is the paradise of the Hindu god, Indra (q.v.). It is the residence of some of the inferior gods and deified mortals, who there rest in the shade of the five wonderful trees—*Mandāra*, *Pārijāta*, *Santāna*, *Kalpavṛksha*, and *Harikāndana*, drink *Amrīta*, or the beverage of immortality; and enjoy the music of the *Gandharvas*, and the dancing of the heavenly nymphs, the *Apsarasas*.

SWARMING, a peculiar mode of reproduction which has been observed in some of the *concretaea*, *desmidiæ*, etc. The granules which form the green matter in the plant, or in one of its joints, become detached from each other, and move about in the cell with great rapidity. The external membrane swells in one point and finally bursts there, when the granules escape into the surrounding water to become new plants. At first they issue in great numbers, but those which remain fast move about within their cell for a long time before they find the way out. Their motion is supposed to be due to cilia. After escaping, they continue their movements for some time, and most of them finally become grouped together in little masses on some substance before beginning to vegetate.

SWATOW, or CHAU-CHAU, a sea-port t. on the coast of China, in the province of Quang-tung, 212 m. n.e. from Canton. It is one of the ports which were opened to foreign trade by the treaty of Tien-tsin, and has a resident British consul. The trade is rapidly increasing. In 1875-77 the imports were valued at £1,787,090, and the exports at £367,400. Half the total is direct trade with foreign ports. Opium is the chief article of importation, next to which rank cotton and woollen goods, metals and cotton yarn. The chief exports are sugar, rice, tea, and paper. Swatow is pleasantly situated on a sheltered bay.

SWAYNE, JOHN WAGER, b. Columbus, Ohio, 1835; son of judge Noah H.; graduate of Yale college, 1856; studied law and commenced practice in his native town. In the war of the rebellion he was maj. 43d Ohio infantry, 1862; raised to col. after effective service at Iuka and Corinth. He served through the Georgia campaign, lost a leg at Salkahatchie, where he greatly distinguished himself, and was made maj.gen., 1865, and assigned to the commission on refugees, freedmen, and abandoned lands. He was commissioned col. 45th infantry, 1866; retired, 1870.

SWAYNE, NOAH HAYNES, LL.D., b. Va.; admitted to the bar in 1824, and began practice in Ohio. He was a member of the state legislature in 1829, and again in 1836. He was U. S. district-attorney, 1830-39, and was appointed a justice of the U. S. supreme court in 1861.

SWE'ABORG, or SVE'ABORG, a great Russian fortress in the principality of Finland, and government of Viborg, sometimes called "the Gibraltar of the north," protects the harbor and town of Helsingfors, from which it is only 3 m. distant. The fortifications extend over seven islands, the *Nylandischen Skären*, but the grand central point is the island of Wargöe. The islands are connected with each other by means of bridges, and between two of them lies the single narrow entrance to the harbor, which can hold from 70 to 80 ships of the line. Swe'aborg has a civic pop. of about 3,000, the greater part of whom are manual-laborers, ship-carpenters, and traders, and a garrison of some 5,000 men (including women and children). During the Crimean war the Anglo-French fleet in the Baltic made a reconnaissance of the place, and bombarded it for two days (Aug. 9 and 10, 1855), but found the defenses too formidable to be reduced by the means at their disposal.

SWEARING, PROFANE, according to the law of England, is an offense for which the party may be convicted by a justice of the peace according to a scale of penalties. A day laborer, common soldier, sailor, or seaman forfeits 1s per oath; every other person under the degree of a gentleman, 2s; and every person above the degree of a gentleman, 5s—for a second offense double these sums; for a third treble, etc. If the cursing take place in the presence of a justice of the peace, the latter may convict the prisoner then and there, without further process or evidence; and in all cases a constable may apprehend a profane swearer, and carry him before a justice. On a recent occasion a man swore a volley of oaths, twenty times repeating the oath, and the justices fined him 2s for each repetition, making in all £2, and this was held a proper conviction. The justices of the peace in Scotland have a similar jurisdiction intrusted to them, to convict of profane swearing, and fine according to the rank of the party.

SWEAT (A. S. *swat*, Sansc. *svaidas*, Lat. *sudor*; Gr. *hydor*, moisture; Lat. *ud(us)* = wet), or perspiration. The nature, composition, and uses of this fluid in the normal state have been sufficiently noticed in the article **SKIN**. It may be additionally remarked, in connection with the physiology of sweat, that the composition of this fluid varies materially according to the part of the body from which it is secreted. Thus Funk found the sweat of the feet was richer in fixed salts than that of the arm, in the ratio of 5 to 3; and Schotten found a considerable preponderance of potassium in the former. In the negro, Dr. Copland and other observers have found that both the gaseous exhalations from the skin, and the solid matters contained in the sweat, were much greater than in the white races. It has been shown in the article **SKIN** that the sweat-glands, like the lungs and kidneys, act as depurating organs, and separate and carry off effete matters from the blood. This eliminating action of the skin is modified in various diseases; in some cases being diminished, as in the early stage of fevers, in inflammations before suppuration commences, in scurvy, diabetes, sunstroke, etc., while it is more or less increased in the sweating stage of ague, in acute rheumatism, in Asiatic cholera, in certain adynamic fevers, in the advanced stages of pulmonary consumption, in the formation of matter in internal parts, etc. The sweat is naturally acid in health, but in prolonged sweating the secretion becomes neutral, and finally alkaline. Little is known with certainty regarding the coloring matters of sweat. In cases of jaundice, the sweat sometimes communicates a yellow tinge to the body-linen; and instances of blue, red, and bloody sweat are on record. Cases of sweat of these colors are recorded in Simon's *Animal Chemistry* (Syd. Soc. Trans.), (London, 1845), vol. ii., p. 110. Cases of unilateral sweating, stopping abruptly at the middle line, have been occasionally noticed, especially in aneurism of the aorta.—See Gairdner's *Clinical Medicine*, page 557. Dr. Druitt has pointed out the use of hot-water as a remedy for profuse perspiration. He has found it serviceable in (1) oversweating in good health and hot weather; (2) undue sweating in special parts of the body, as the hands, feet, or armpits; (3) true hectic; and (4) ordinary night sweats in phthisis not preceded by hectic symptoms. To be of any service, the water must be applied at as great a heat as the patient can possibly bear (see his paper on this subject in the *Medical Times* for March 4, 1865). For a very interesting and learned discussion on our Saviour's bloody sweat during his passion, the reader may consult Stroud *On the Physical Cause of the Death of Christ*, and Trusen's chapter *Von dem Blutschweisse Christ* in his *Darstellung der Biblischen Krankheiten*, 1843.

SWEATING SICKNESS, *Thré*, is the term given to an extremely fatal epidemical disorder, which ravaged Europe, and especially England, in the 15th and 16th centuries. It derives its name "because it did most stand in sweating from the beginning until the endyng," and "because it first beganne in Englande, it was named in other countries the Englishe sweat."—*The Boke of Jhon Catus against the Sweating Sicknes*. It first appeared in August, 1485, in the army of Henry VII., shortly after his arrival at Milford in South Wales from France, and in a few weeks it spread to the metropolis. It was a violent inflammatory fever, which, after a short rigor, prostrated the powers as with a blow; and amid painful oppression at the stomach, headache, and lethargic stupor, suffused the whole body with a fetid perspiration. All this took place in the course of a few hours, and the crisis was always over within the space of a day and night. The internal heat which the patient suffered was intolerable, yet every refrigerant was certain death. "Scarcely one amongst a hundred that sickened did escape with life."—Holinshed, vol. iii. p. 482. Two lord mayors of London and six aldermen died within one week; and the disease for the most part seized as its victims robust and vigorous men. It lasted in London from the 21st (some authorities say the middle) of September to the end of October, during which short period "many thousands" died from it. The physicians could do little or nothing to combat the disease, which at length was swept away from England by (as many supposed) a violent tempest on New Year's day. The disease did not re-appear till the summer of 1506, when it broke out in London, but does not seem to have occasioned any great mortality. In July, 1517, it again broke out in London in a most virulent form; it being so rapid in its course that it carried off those who were attacked in two or three hours. Among the lower classes, the deaths were innumerable, and the ranks of the higher classes were thinned. In many towns a third, or even a half of the inhabitants were swept away. On this occasion, the epidemic lasted about six months. In May, 1528—the year in which the French army before Naples was de-

stroyed by pestilence, and in which the putrid fever known as *Trousse-galant* decimated the youth in France—the sweating sickness again broke out in the metropolis, spread rapidly over the whole kingdom, “and fourteen months later, brought a scene of horror upon all the nations of northern Europe scarcely equaled in any other epidemic.—Hecker’s *Epidemics of the Middle Ages*, (Syd. Soc. Trans.), p. 238. How many lives were lost in this epidemic, which has been called by some historians *the great mortality*, is unknown; but the mere fact that the king (Henry VIII., who, whatever his faults, was never accused of cowardice) left London, and endeavored to avoid the disease by continually traveling, shows the general feeling of alarm that existed. In the following summer (July 25, 1529), having apparently died out in England, it appeared in Germany, first at Hamburg, where it is recorded that 8000 persons died of it, and shortly after at Lubeck, Stettin, Augsburg, Cologne, Strasburg, Hanover, etc. In September, it broke out in the Netherlands, Denmark, Sweden, and Norway, whence it penetrated into Lithuania, Poland, and Livonia. By January of the following year, after an existence of three months, it had entirely disappeared from all these countries. For three-and-twenty years the sweating sickness totally disappeared, when for the last time (April 15, 1551) it burst forth in Shrewsbury. The banks of the Severn seemed to be the focus of the malady, which was carried from place to place by poisonous clouds of mist. There died within a few days 960 of the inhabitants of Shrewsbury, the greater part of them robust men and heads of families. The disease spread rapidly over the whole of England, but seems to have disappeared by the end of September. The deaths were so numerous, that one historian (Stow) states that the disorder caused a *depopulation* of the kingdom. The very remarkable observation was made in this year, that the sweating sickness uniformly spared foreigners in England, and on the other hand, followed the English into foreign countries. The immoderate use of beer among the English was considered by many as the principal reason why the sweating sickness was confined to them. “By the autumn of 1551,” says Hecker, “the sweating sickness had vanished from the earth; it has never since appeared as it did then and at earlier periods; and it is not to be supposed that it will ever again break forth as a great epidemic in the same form, and limited to a four-and-twenty hours’ course; for it is manifest that the mode of living of the people had a great share in its origin, and this will never again be the same as in those days.”—*Epidemics of the Middle Ages* (Syd. Soc. Trans.), p. 306.

SWEDEN, *Sverige*, the eastern portion of the Scandinavian peninsula, constitutes with Norway (q.v.) one joint kingdom. It is situated in 55° 20'—69° 3' n. lat., and 11°—24° e. long., and is bounded on the n. and w. by Norway; on the extreme s.w. and s. by the Cattegat, which separates it from Denmark; on the s.e. and e., as far as 66° n. lat., by the Baltic and the gulf of Bothnia; and from thence to the extreme n. by Russia. The area is nearly 170,000 sq. m.; and the pop. was, in '71, 4,204,177. Its length is 969 m., and its greatest width from 150 to 280 miles. Sweden is divided into three provinces—viz., Norrland, the largest and most northern; Sweden Proper, or *Svea-rike* (land of the Swedes), in the center; and Götaland or *Göta-rike* (land of the Goths), to the south. The following are the areas and populations of the 25 län into which the provinces are subdivided (in '78 the total pop. was estimated at 4,485,000):

Län.	Area in Geog. Sq. Miles.	Population in Dec. 1871.
Stockholm.....	135.5	131,731
Upsala.....	94.9	101,731
Södermannland.....	122.4	126,977
Oestergötland.....	194.9	257,267
Jönköping.....	202.2	180,569
Kronoberg.....	180.7	159,258
Kalmar.....	209.1	231,597
Götland.....	57.	54,237
Bläkinge.....	54.7	126,935
Kristianstad.....	117.9	233,492
Malmöhus.....	86.8	318,786
Halland.....	89.3	127,842
Göteborg and Bohus.....	91.8	233,680
Friksborg.....	232.7	286,454
Skaraborg.....	155.6	254,691
Vernland.....	306.6	261,716
Orebro.....	164.7	169,219
Vestmannland.....	119.9	115,665
Kopparberg.....	528.7	176,946
Giefelborg.....	351.	150,374
Vesternorrland.....	447.5	136,939
Jemtland.....	921.2	71,393
Vesterbotten.....	1122.5	63,164
Norbotten.....	1931.8	77,328
	8078.8	4,065,665
City of Stockholm.....		138,512
Total population.....		4,204,177

In 1878 Sweden ceded her only colony, St. Bartholomew (q.v.), to France (to which country it once belonged) on payment of the purchase money agreed on.

Unlike Norway, Sweden possesses few high mountains, but contains numerous lakes of large dimensions. The coast skirting the Baltic, and the adjoining islands, are for the most part low and sandy, although in some parts, as in the vicinity of the outlet of lake Maclar into the sea (in about 58° n. lat.), the shores are steep; and on the s. and w. coast, the generally low, alluvial lands are replaced by more rocky formations.

In the northern parts the land rises gradually from the gulf of Bothnia to the Kjölen range, belonging to the great Norwegian Fjeldmark, which constitutes the true watershed and natural boundary between Sweden and Norway. South of 62° n. lat., the slope is directed southward, attaining its lowest level in the vicinity of the three great lakes of Vener, Maclar, and Hjelmar, which, together with the great Vetter lake, nearly intersect the country from e. to w.; and s. of these great inland waters, the surface is in general level, though ranges of high ground and detached hills occur.

Sweden may be considered to be divided into three distinct parts—viz., the northern or alpine region, the central or lake district, and the southern or mining district. The extreme s. includes the only level and fertile tract, in which wheat can at all times be advantageously and extensively cultivated. The lakes of Sweden have been computed to cover nearly $\frac{1}{4}$ th of the entire area of the country. The largest are lake Vener (q.v.); lake Vetter (q.v.); and the Maclar lake (q.v.). The rivers are generally short and rapid, and only made navigable by art. The largest is the Ängermann Elv, which flows into the gulf of Bothnia. The Cättegat is connected with the Baltic by means of an admirable system of canals, etc.

Temperature, Natural Products, etc.—The differences of climate in Sweden are necessarily very great, considering that its most northern parts are more than 2° within the polar circle, and its southern extremity 11° s. of it, besides which many districts are so nearly surrounded by seas and lakes as to have the conditions of an insular position. Great extremes of temperature are common in different parts of Sweden; thus, while Stockholm has a mean annual temperature of $42^{\circ}.2$ Fabr., and Göteborg $46^{\circ}.3$, the summer temperature of the former is $60^{\circ}.4$ Fabr., and that of the latter $62^{\circ}.13$; and the winter temperature of the former only $25^{\circ}.8$, and that of the latter $31^{\circ}.5$ Fabr.

The heat of the summer, which is scarcely separated from the cold of the winter by either spring or autumn in the extreme northern districts, enables the inhabitants to cultivate barley, which is reaped within two months of the time of its sowing, although even the hardier cereals, as oats and rye, will not ripen above the parallel of 66° n. lat. Indeed, the climate of Sweden generally is unfavorable to the growth of grain, the annual yield of which frequently falls short of the wants of the population. The principal articles of cultivation are, in addition to the various cereals, potatoes, hemp, flax, tobacco, and hops, which are generally grown in sufficient quantities for home consumption. The forests are of great extent, covering nearly one-fourth of the entire surface, and rising at some spots to an elevation of 3,000 ft. above the level of the sea. The birch, fir, pine, and beech are of great importance, not only for the timber, tar, and pitch, which they yield, but also from their supplying charcoal and firewood. Above the parallel of 64° , stunted bushes, berries, dwarf-plants, and lichens are the only forms of vegetation to be met with. The common fruit-trees, as cherries, apples, and pears, grow as far north as 60° , but the fruit seldom comes to great perfection except in the southern provinces; cranberries and other berries abound, however, in all parts of the country. Bears and beavers, which were formerly often met with, are becoming scarce; but wolves, lynxes, foxes, martens, squirrels, eagles, reindeer in the Lappmarks, etc., are still common; while the elk and deer are found in some of the forests, which abound in hares, woodcock, blackcock, and various other kinds of small game; and lemmings (q.v.) occasionally descend from the mountains in large numbers, and lay waste the low country. The lakes yield a great abundance of fish, 88 different kinds of sea and freshwater fish being brought to market. In 1870, there were in Sweden 428,446 horses, 1,965,800 horned cattle, 1,780,000 sheep and goats, and 354,303 swine.

The mineral products of Sweden, which are extremely rich, include some gold and silver (which, however, do not pay the cost of working), copper in abundance, iron of the finest quality, alum, vitriol, marble, sulphur, lead, plumbago, cobalt, nickel, zinc, and some coal of very inferior quality.

Next to agriculture, mining constitutes the most important branch of national industry, and in some provinces is the principal employment. The Danemora mines, in Upsal Län, yield a metal which is capable of being converted into the finest steel, and which is for the most part purchased for the English market. At Gellivare in south Lapland enormous quantities of iron ore of superior quality have recently been extracted from mines, which promise to rival those in Upsala.

Ship-building forms an extensive branch of local industry. The merchant-sailing marine numbered in 1874, 4,338 vessels with a tonnage of about 450,000; the number of vessels that cleared the Swedish ports in 1876, was 16,775, with a tonnage of about 2,533,500, of which one-third belonged to Sweden.

Exports and Imports.—The chief articles of export are iron and timber, copper, cobalt, alum, hemp, oil, birch-bark, hides, furs, paper, tobacco, home-spun linens, pitch

and tar, etc. The Baltic lands, Great Britain, France, Portugal, and the Brazils take the greater part of these articles. The imports include yarn, wool, cotton, leather, coals, salt, machines, manure, textile fabrics, wines, and the ordinary colonial produce. The value of the imports in 1874 was 306,810,000 rixdalers, or about £18,111,670; that of exports, 243,332,000 rixdalers, or about £12,962,914.

In 1858 the decimal was introduced into Sweden, when the standard foot, which was retained, was divided into 10 in. of 10 lines, and the old standard pound made the basis of the hundredweight of 100 pounds. The rixdaler rixmynt = 100 oere, or about 1s. 2d., now usually called *krona*, has been made to supersede the old rixdaler-banco of 150 oere.

Revenue, etc.—The revenue is derived from direct and indirect taxation, state property, railways, customs, etc. The budget for 1877 gave the annual receipts at 78,258,000 rixdalers, or about £4,347,670, and the expenditure at the same figure; of which about 10,000,000 rixdalers were for extraordinary expenses. The frequent surplus of expenditure, which is almost invariably due to the prosecution of national and public works, is formally sanctioned by the diet, which annually provides means for covering the deficit by the appropriation of certain state funds for the purpose, and by the levying of a general income-tax. At the end of 1877 the national debt of Sweden was 182,157,84 rixdalers or crowns, nearly four-fifths of which are held by foreigners.

Army, Navy, etc.—The Swedish army, which is nominally rated at about 150,000 men, has a special and peculiar organization, as it consists, in addition to the *värfvade* or enlisted troops, of the "indelta," or cantoned militiamen, who are maintained at the cost, and on the property, of the landed proprietors: each estate being mulcted according to its value or extent to maintain one or more men, and provide them with "torps" or cottages, a certain portion of land, and a fixed rate of payment. In return these reserve soldiers, who are for the most part married men, serve the proprietor as field-laborers in times of peace, except during the four weeks of each year in which they are called out for drill. In case of war they can be sent with the companies in which they are enrolled into active service, and they are then paid by the crown. The rest of the army is made up of volunteers, who serve for six years, every Swede between the age of 20 and 25 years being, moreover, bound to serve in the *beväring* or national guard. In addition to these corps, companies of volunteer free-shooters were created in 1861 for the general defense of the country, and placed under the command of officers appointed by the crown. The fleet consisted in 1878 of 150 vessels (of which 52 were steamers), carrying in all about 400 guns. There are on an average 7,800 men engaged in active service: while in time of war, a coasting merchant fleet of 3,200 vessels can be called into requisition, together with a reserve of 25,000 men. The principal fortresses are Karlssten, Karlskrona, and Vaxholm near Stockholm. The military and other orders are the Seraphim, the Sword, the Northern Star, and the Order of Vasa. The order of Charles XIII. embraces the highest rank of freemasons in Sweden.

Form of Government.—Sweden is a hereditary and constitutional monarchy, based on the fundamental law of 1809, by which it was decreed that the succession should be in the male line; that the sovereign should profess the Lutheran faith; and have sworn fidelity to the laws. The diet, which meets every year, and remains sitting for three or four months, is composed of two chambers, which are both elected by the people. The first chamber consists of 127 members, who receive no payment, and are elected for nine years, their number being, however, dependent upon the amount of the population. They must be possessed of an income of about £225, and have attained the age of 35. The second chamber is composed of 194 members, elected for three years, on a lower scale of qualification as to property and age; and receiving payment for their attendance during each session of the diet, and for their traveling expenses. Election to both chambers is by ballot. The diet exercises a strict control over the expenditure of the revenue, fixes the budget, and has power to take cognizance of the acts of the ministers and crown officers. The king's person is inviolable, and he can exercise a veto on the decrees of the diet. He is the supreme head of the law courts, nominates to all appointments, can declare war, make peace, and conclude foreign treaties. He is assisted by a council of state composed of 10 members, who are responsible to the diet.

Law, etc.—The administration of the law is independent of the state, and presided over by the chancellor of justice, *justitie kanslar*, appointed by the king, and an attorney-general, *justitie ombudsmann*, appointed by the diet. There were 587,581 cases brought before the courts in 1875, the large proportion of which were merely for slight offenses against the law. The expenses incurred annually for the support of the poor are about 6,000,000 rixdalers, which is nearly covered by the regular income obtained by the rates imposed for the purpose.

Sweden is divided administratively into 25 *läns*, presided over by *länsmen* or chief magistrates, and subdivided into 117 *fögderin*, and 517 *länsmans* districts. There are 90 chief towns (*städer*), only a limited number of which have the right of trading with foreign ports, and 19 market-towns (*Köpingar*). Besides Stockholm, the capital (q.v.), only one town, Göteborg (71,000 in 1877), has a pop. of more than 50,000. Next in rank come Malmö, with 34,439; Norköping, with 27,226; Gelle, with 18,137; and Karlskrona,

with 17,787 inhabitants. Upsala, a cathedral and university town, which is the most interesting spot in the kingdom, as the original seat both of Christianity and of the ancient Odinic faith, has a pop. of only 13,446.

Religion, etc.—The predominant form of religion in Sweden is the Lutheran; the official tables of the census for 1870 showing only 6,440 persons who belonged to other forms of faith, of whom 1918 were Baptists, and 1836 Jews. The affairs of the church are administered by 1 archbishop (of Upsala) and 11 bishops, whose collective dioceses include about 2,500 parishes, with about 3,500 pastors.

Education, etc.—Education is universally diffused among the Swedes by the agency of *fasta* (regular) and *flyttanda* (ambulatory) schools in all the country districts. There were, in 1869, 2,303 of the former and 1206 of the latter kind, together with 3,410 infant schools, which were attended in all by 679,128 children, and instructed by 5,030 male and 2,115 female teachers. Public instruction is compulsory for all children, and the cost is defrayed by the nation. Ample means are supplied for a higher form of instruction in the *läroverk* or gymnasia of the towns, and at the universities of Upsala and Lund. The Karolinska institute at Stockholm is the medical college of Sweden; and there are numerous technical, military, and other special collegiate institutions in the principal towns of the kingdom. The transactions of the two learned societies, the "Svenska Vetenskaps Selskap," and the "Svenska akademie," afford honorable testimony to the advanced condition of scientific inquiry in Sweden. The royal library of Stockholm and those of Upsala and Lund number about 100,000 vols. each. That of Upsala is contained in a special building, *Carolina Rediviva*, to which is attached a botanical garden arranged on the Linnean system.

Roads, Railways, etc.—There were, in 1878, 12,000 English miles of high-roads in Sweden, and nearly double that length of way in parish and by-roads. In 1877 a length of 3,010 English miles of railway had been opened. In the year 1871 the number of passengers conveyed was 1,659,204, and the receipts from this branch of the traffic were 2,896,184 rixdalers; while the whole of the returns were 7,784,860 rixdalers (£432,490). In 1875 the telegraphic lines measured 4,991 English miles, and, besides the 170 government telegraph stations, there were 351 stations in connection with railways and belonging to companies; 1,009,539 messages were transmitted, of which number 645,913 were from and for Sweden; and the receipts were for the same year 1,953,109 rixdalers. There passed 16,250,000 letters through the post-offices of Sweden in 1875, when the receipts were 3,650,000, and the expenses of the department 3,700,000 rixdalers.

History.—The legendary history of Sweden forms part of Scandinavian history. When we first hear of Sweden the country was inhabited by numerous tribes, kindred in origin but politically separate. Two principal groups, however, are recognizable—*Goths* in the south and *Sveedes* in the north. These possessed in common a national sanctuary, the temple of Uppsala, which laid the basis of a later unification, for gradually the royal chieftains of Uppsala extirpated the inferior princes, the *Härad*s and the *Fylkis*. Ingiald Hrada, the last ruler of the old royal family of the *Ynglingar*, who drew their origin from *Njord*, sought to establish a single government in Sweden, and perished in the attempt. To the *Ynglingar* followed in Upland the dynasty of the *Skjoldungar*, which claimed to be descended from *Skjold*, son of *Odin*. *Erik Edmunds-son*, who belonged to this dynasty, is said to have acquired the sovereignty of the whole of Sweden about the end of the 9th century. The dawn of Swedish history (properly so called) now begins, and we find the Swedes constantly at war with their neighbors of Norway and Denmark, and busily engaged in piratical enterprises against the eastern shores of the Baltic. See *NORMANS* and *RUSSIA*. Efforts to introduce Christianity (see *ANSGAR*) were made as early as 829 A.D., but it was not till 1000 A.D. that *Olof Skötkonung*, the Lap-king, was baptized, nor did the struggle between heathenism and the new religion cease till the burning of the temple of Upsala in the reign of *Inge* (1080–1112). In 1155 *Erik*, surnamed the saint, gave a powerful impetus to the diffusion of Christian doctrines by building churches and founding monasteries. He undertook a crusade against the pagan Finns, and, having compelled them to submit to baptism, and established Swedish settlements among them, he laid the foundation of the union of Finland with Sweden. *Erik's* defeat and murder in 1160 by the Danish prince *Magnus Henriksen*, who made an unprovoked attack upon the Swedish king, was the beginning of a long series of troubles, and during the following 200 years, one short and stormy reign was brought to a violent end by murder or civil war only to be succeeded by another equally short and disturbed. At length, in 1389, the throne was offered by the Swedish nobles to *Margaret*, queen of Denmark and Norway, who, having gladly availed herself of the opportunity thus opened to her of uniting the three Scandinavian crowns into one, threw an army into Sweden, defeated the Swedish king *Albert* of Mecklenburg, who on the deposition of his maternal uncle *Magnus* had been called to the vacant throne, and by the union of *Calmar* in 1397 brought Sweden under one joint scepter with Denmark and Norway. In 1523 Sweden emancipated itself from the union with Denmark, which during the reigns of *Hans* and his son *Kristian II.* (see *DENMARK*) had become hateful to the Swedes, and rewarded its deliverer, young *Gustaf Vasa* (see *GUSTAVUS I.*), by electing him king and declaring its independence of Denmark. *Gustaf Vasa* found an empty treasury, a kingdom exhausted by war, a haughty nobility and clergy (who arrogated the right of electing the sovereign, and who claimed exemption from all

imposts), and a people overburdened with taxation and bad government and divided in regard to religion. On his death in 1560 he left to his successor a hereditary and well-organized kingdom (in which the power of the nobles had been circumscribed, and that of the clergy broken, by the abrogation of Catholicism and the firm establishment of the reformed church under the jurisdiction of the state), a full exchequer, a standing army, and a well-appointed navy. Trade, manufactures, art, learning, and science owed their advancement in Sweden to this patriotic king.

The colossal labors of the great Vasa in raising a semi-barbarous state to an honorable place among the civilized monarchies of Europe, were rendered almost useless by the crimes and misfortunes of his son and successor, Erik XIV., whose high intellectual powers were clouded by a wayward and revengeful nature, leading him finally to insanity. His cruelties and excesses led to his deposition in 1568, when his younger brother Johan ascended the throne, which he occupied for nearly a quarter of a century, dying in 1592, after a stormy reign, stained by the cruel murder of his unfortunate brother Erik, and distracted by the internal dissensions arising from his attempts to force Catholicism on the people, and to carry on war with the Danes, Poles, and Russians. Johan's son and successor, Sigismund, who had been elected king of Poland through the influence of the relatives of his Polish mother, after a short and stormy reign of eight years, which were spent in attempting to restore Catholicism in Sweden, was compelled by the diet to resign the throne in 1599 to his uncle Karl, the only one of Gustaf Vasa's sons who inherited any share of his legislative and administrative talents. The policy of Karl IX., was to encourage the burgher classes at the expense of the nobility; and by his successful efforts to foster trade—in furtherance of which he laid the foundation of Göteborg and other trading ports—develop the mineral resources of the country, and reorganize the system of Swedish jurisprudence, he did much to retrieve the calamitous errors of his predecessors. The deposition of Sigismund gave rise to the Swedo-Polish war of succession, which continued from 1604 to 1660; and on the death of Karl in 1611, his son and successor, the great Gustavus Adolphus, found himself involved in hostilities with Russia, Poland, and Denmark. By the ability of his minister, Oxenstierna, the young king was soon enabled to conclude treaties of peace with his northern neighbors, and to place the internal affairs of his kingdom in order (see GUSTAVUS II.); and although he justly ranks as one of the greatest military commanders of his age, the extraordinary number of benefits which he conferred on every department of the administrative system of Sweden, entitle him to still greater renown as the benefactor of his native country. His death in 1632, on the field of Lützen, would have proved an irreparable calamity to Sweden, had not the able administration of Oxenstierna, during the minority of Gustavus's daughter, Christina, maintained the renown of the Swedish arms abroad, and the political reputation of the country among the other states. The reign of Christina (q.v.) was disastrous in every act but that of her abdication. The short reign of Karl X. was occupied in generally unsuccessful wars against Poland and Denmark; while the minority and long rule of his son, Karl XI.—from 1660 to 1697—was characterized by success abroad, and in the augmentation of the regal power, which was declared by an act of the diet to be absolute. His son Karl, known to us as Charles XII. (q.v.), succeeded, at the age of 15, to the power and dominions which his father's abilities had consolidated, but which, notwithstanding his own brilliant genius, he so deeply imperiled by his insatiable ambition, that at his untimely death in 1718, at the siege of Frederikshald, after a brilliant career of glorious but checkered military achievements, he left his country overwhelmed with debts, and disorganized by prolonged misrule. With him the male line of the Vasas expired, and his sister and her husband, Frederick of Hesse-Cassel, were called to the throne by election, but were the mere puppets of the nobles, whose rivalries and party dissensions plunged the country into calamitous wars and almost equally disastrous treaties of peace, and, under the leadership of the two great factions of the "Hats," or French party, and the "Caps," or Russian party, demoralized all ranks of society. The weak Adolphus Frederick of Holstein-Gottorp, who was called to the throne on the death of Frederick in 1751, and died in 1771, did little to retrieve the evil fortunes of the state; but his son, Gustavus III. (q.v.) (1771-92), skillfully turned to account the general dissatisfaction of the people with the nobles, to destroy the factions of the Hats and Caps, and to recover the lost power of the crown. His extravagance, dissoluteness, and insincerity detracted, however, from his merits as a ruler, and raised up numerous enemies against him, through whose agency he was assassinated in 1792. His son and successor, Gustavus IV. (q.v.) lacked the ability to cope with the difficulties of the times, and after suffering in turn for his alliance with France, England, and Russia, was forcibly deposed in 1809, and obliged to renounce for himself and his direct heirs the crown in favor of his uncle, Charles XIII., who saw himself compelled at once to conclude a humiliating peace with Russia by the cession of nearly a fourth part of the Swedish territories, with $1\frac{1}{2}$ million of inhabitants. The early part of the reign of Charles, who was childless, was troubled by domestic and foreign intrigues to regulate the choice of an heir to the throne; and when, under the erroneous idea of conciliating Napoleon, the dominant party in Sweden elected General Bernadotte to the rank of crown prince, the latter assumed the reins of government, and by his steady support of the allies against the French emperor, secured to Sweden at the congress of Vienna, the possession of Norway, when that country was separated from Den-

mark. Under the able administration of Bernadotte, who, in 1818, succeeded to the throne as Charles XIV., the united kingdoms of Sweden and Norway made great advances in material prosperity and political and intellectual progress; and although the nation at large entertained very little personal regard for their alien sovereign, his son and successor, Oscar (1844-59), and his grandsons, the late king, Charles XV., and the present king, Oscar II., who came to the throne in 1872, have so identified themselves with their subjects that the Bernadotte dynasty has secured the loyal affections of every section of the united nations of Sweden and Norway.

SWEDENBORG, EMANUEL, was b. in Stockholm, Jan. 29, 1688, and died in London, Mar. 29, 1772. His father was Jesper Svedberg, subsequently bishop of Skara. Swedenborg's lifetime divides itself into two distinct periods; the first, ending with his 55th year, was given to business, science, and philosophy; the second, of nearly 30 years, was consecrated to theology and spiritualism. Swedenborg was educated at Upsal, and traveled for four years in England, Holland, France, and Germany. On his return to Sweden, he was appointed by Charles XII. to an assessorship of mines; and rendered some service to that monarch as military engineer. The Swedenborg family was ennobled in 1719, and the name changed from Svedberg to Swedenborg. Swedenborg is sometimes styled count and baron, but erroneously; he was neither, though he had a seat in the Swedish house of nobles. His mind at this time was busy with mechanical and economical projects. He published short treatises on algebra, giving the first account in Sweden of the differential and integral calculus; on a mode of finding the longitude at sea by the moon; on decimal money and measures; on the motion and position of the earth and planets; on the depth of the sea, and greater force of the tides in the ancient world; on docks, sluices, and salt-works; and on chemistry as atomic geometry. In 1724 he was offered the professorship of mathematics at Upsal, which he declined from a dislike of speculative science. Abandoning his desultory studies, he remained silent for eleven years, and devoted himself to the duties of his assessorship and to a systematic description of mining and smelting, and the construction of a theory of the origin of creation. The result appeared at Leipzig in 1734, in three massive folios, beautifully illustrated, entitled *Opera Philosophica et Mineralia*. The second and third volumes describe the manufacture of copper, iron, and brass, and contain an exhaustive record of the best methods in use in last century. The first volume, entitled *Principia, or the First Principles of Natural Things, being new Attempts toward a Philosophical Explanation of the Elementary World*, is an elaborate deduction of matter from "points of pure motion produced immediately from the infinite." This was followed in 1734 by a treatise on *The Infinite, and the Final Cause of Creation; and the Intercourse between the Soul and the Body*, carrying the doctrine of the *Principia* into higher regions, and resolving the soul into points of motion, and one in substance with the sun. Dissatisfied with his conclusions, he determined to track the soul to its inmost recesses in the body. His studies in human anatomy and physiology with this end in view, appeared as *Oeconomia Regni Animalis*, in two volumes, 1741, and as *Regnum Animale*, in three volumes unfinished, 1744-45. At this point, his course was arrested, and he entered on his career as seer, by which he is known to fame. The particulars of the transition lay in obscurity until 1858, when G. E. Klemming, royal librarian, Stockholm, discovered Swedenborg's diary, kept in 1744. It contains the record of a variety of dreams, visions, and strange communings. After that date, he professed to enjoy free access to heaven and hell. He resigned his assessorship in 1747, that he might devote himself to his office of seer. In 1749 he made his first public appearance in his new character in the issue in London of the *Arcana Cælestia*, completed in 1756 in eight quartos. His life henceforward was spent between Stockholm, London, and Amsterdam, in writing and printing a variety of works in exposition of his experience and doctrines. There is little in any of these which is not comprised in the *Arcana Cælestia*, and a few notes on its contents may serve as a description of the whole. With many digressions, the *Arcana Cælestia* is a revelation of the inner sense of Genesis and Exodus. The early chapters of Genesis are a fragment of an older word, preserved at this day in Tartary, and are not historical in a manner-of-fact sense. Adam signifies the most ancient church, and the flood its dissolution; Noah, the ancient church, which falling into idolatry, was superseded by the Jewish. The spiritual sense pervades the Scriptures, with the exception of Ruth, Chronicles, Ezra, Nehemiah, Esther, Job, Proverbs, Ecclesiastes, the Song of Solomon, the Acts of the Apostles, and the Epistles. No fault is found with these books, but inasmuch as they do not possess the internal sense, they are not the word. The Scriptures are read in heaven in the spiritual sense, but as that sense treats exclusively of God and the human mind, it is void of every reference to earthly scenes, persons, and events. By reason of its symbolism of the inward sense, the letter of Scripture is holy in every jot and tittle, and has been preserved in immaculate perfection since the hour of its divine dictation. The Jewish dispensation having reached its period, God appeared in Jesus Christ. He assumed human nature in its basest condition in the Virgin, wrought it into conformity with himself, "glorified and made it divine." The influence from the redeemed humanity is the Holy Spirit. In a sense the reverse of Socinian, Swedenborg was a Unitarian. He saw God in the Savior, and regarded him as the sole object of worship. The church initiated by the divine advent came to an end in last century, and Swedenborg witnessed the last judg-

ment effected in the year 1757 in the world of spirits. Then commenced a new dispensation, signified by the New Jerusalem in the Revelation, of which Swedenborg was the precursor, and his writings the doctrine. To the objection, that the doctrine is strange and novel, he replied, that mankind were not prepared for its reception, and that the early Christians were too simple to understand it.

One of the chief ends of his mission was the revival of the lost science of correspondences—the science of sciences in the most ancient times. The law of correspondence is universal; the natural world is the outbirth of the spiritual world, and the spiritual world of the invisible mental world. Unseen evil is manifested in things hurtful and ugly; unseen good, in things useful and beautiful. Man is a summary of nature; nature is man in diffusion; all things, therefore, in nature, in fire, air, earth, and water—every beast, bird, fish, insect, and reptile—every tree, herb, fruit, and flower, represent and express unseen things in the mind of man. The Scriptures are written according to correspondences, and by aid of the science their mysteries are unlocked. By it, too, the constitution of heaven and hell is revealed. There are three heavens, consisting of three orders of angels; the first distinguished for love, the second for wisdom, and the last for obedience. All angels have lived on earth; none were created such. They are men and women in every respect; they marry, and live in societies in cities and countries just as in the world, but in happiness and glory ineffable. All in whom love to God and man is the ruling principle, go to heaven at death. Between heaven and hell, a perfect equilibrium is maintained. As there are three heavens, there are three hells, and every angelic society has an infernal opposite. Hell, as a whole, is called the devil and Satan; there is no individual bearing that name. All in whom self-love is the ruling motive, go to hell. There is no resurrection of the earthly body. Every one passes to his final lot at death, some making a short sojourn in an intermediate state, designated the world of spirits, where the good are cured of their superficial infirmities and intellectual mistakes, and where the evil are stripped of all their pretenses to good.

Swedenborg professed to enjoy a numerous acquaintance with departed celebrities, and some of his verdicts on character are appalling; for example, he describes king David and St. Paul as among the lost, while Louis XIV. and George II. are distinguished angels. Nor did he confine his intercourse to ghosts from earth, but extended it to souls from the moon and planets, with the unfortunate exceptions of Uranus, Neptune, and the Asteroids. For these visions, enjoyed while sitting in his chamber, he had this explanation: although in the spiritual world there are *appearances* of space, there is nothing of the objective reality which here divides London from Melbourne. If one spirit desires to see another, the desire instantly brings them together. A good man is, as to his mind, in heaven, and an evil man in hell; and supposing the spiritual sight of either was opened—that is, if the eyes of the spiritual body, which transfuse and animate the material ones, were disengaged from their fleshly vesture—he would see his spiritual companions and the country where he would abide after death.

The grand and distinctive principle of Swedenborgian theology, next to the doctrine of the divine humanity, is the doctrine of life. God alone lives. Creation is dead—man is dead; and their apparent life is the divine presence. God is everywhere the same. It fallaciously appears as if he were different in one man and in another. The difference is in the recipients; by one he is not received in the same degree as another. A man more adequately manifests God than a tree; that is the only distinction. The life of devils is God's presence perverted in disorderly forms. "All things, and each of them to the very uttermost, exist and subsist instantly from God. If the connection of anything with him were broken for a moment, it would instantly vanish; for existence is perpetual subsistence, and preservation perpetual creation." By this law of life is explained man's self-consciousness, freedom, and personality. All these sensations are communicated from God to man. He dwells in man so cordially that he gives him to feel that he lives of himself, even as he lives.

Swedenborg made no attempt to establish a sect. When he proclaimed the Christian church at an end his expectation was, that a new church would be raised up among the Gentiles; but toward the close of his life he was silent as to that hope, and spent his energies in attacking Protestant theology, as if bent on the conversion of northern Europe. All his works were written in Latin, and received little attention from his contemporaries. Apart from his visions, there was nothing peculiar about Swedenborg. He was shrewd in worldly affairs, affable in society, and discussed politics and finance in the Swedish diet like a man of the world. He was never married. In diet he was a vegetarian.

Swedenborgians, or, as they designate themselves, "The New Church signified by the New Jerusalem in the Revelation," were first organized as a separate body in 1783 by Robert Hindmarsh, a printer in Clerkenwell, London, who was elected by lot to baptize and to ordain his comrades in the ministry. The Swedenborgians accept Swedenborg's voluminous theological writings as nothing less than revelations from heaven. The body has not had a prosperous existence. The number of its registered members in Britain is little over 4,000, divided into 58 congregations. These are chiefly in the large towns and in Lancashire; four are in Scotland, but none in Ireland. At one time there were reputed to be a number of receivers of the doctrines of Swedenborg among the clergy of the church of England. The translator of the *Arcana Cœlestia* was the

rev. John Clowes, rector of St. John's, Manchester, for sixty-two years. He died in 1831, and in the pulpit and numerous publications made no secret of his faith. In the United States the Swedenborgians have nearly 100 societies, and about 5,000 members. They chiefly exist in the northern states; and their largest congregation is in Boston. In France, Germany, Sweden, and Russia, there are Swedenborgians, but few and scattered. There is a Swedenborg society, established in 1810, for printing and publishing Swedenborg's works, with a house in London, and an income of about £200 a year. See the life of Swedenborg by White (London, 1867), and various *Documents*, published by prof. Tafel (ed. 1875).

SWEDENBORGIANS organized their first congregation in the United States at Baltimore, 1792; and their general convention in 1817, incorporated under the law of Illinois, and having associations, societies, or members, in nearly all the states. It holds annual sessions in different cities, has a publishing house in New York, a theological school at Waltham, Mass., a Sunday-school union and church music society. Much freedom in regard to ecclesiastical forms is allowed, the power to adopt them being lodged in the whole body of members. The form generally preferred in this country is a modified episcopacy: each state association having its overseer, whose office is permanent. In most of the congregations the worship is partly liturgical, and several books of prayer have been issued; yet as each congregation is free to adopt its own mode, in some only extemporaneous prayers are offered. There is a congregational union, composed of ministers and churches preferring that order, having its headquarters in Philadelphia, with its own board of publication. There are also independent societies and churches not associated together. And, while the number of those who, in an open profession of Swedenborgian doctrines, have separated from other Christian churches is not large, they believe that in all other denominations many persons have adopted more or less of Swedenborg's views. And it is their avowed and cherished purpose to enlarge this number everywhere. A large sum of money has been devoted to publishing some of the most popular of Swedenborg's books for gratuitous distribution to all who apply for them; and in a report, made 1878, it is stated that 36,000 vols. had thus been sent to ministers and theological students of all denominations, and of the white, black, and Indian races. At the general convention of 1877, 64 societies were represented, having about 4,800 members.

SWEDISH LANGUAGE AND LITERATURE. See SCANDINAVIAN LANGUAGE AND LITERATURE.

SWEDISH MOVEMENT CURE. See MOVEMENT CURE.

SWEEPS, on shipboard, are oars of great length used in large vessels during a calm, to enable the ship to obtain steerage-way.

SWEETEREAD, the pancreas (q. v.) of an animal, used as food; it is highly esteemed as being both delicate and nutritious.

SWEET-BRIER. See ROSE.

SWEET FLAG. See ACORUS.

SWEET GUM. See LIQUIDAMBAR.

SWEETMEAT, a general term applied to such articles of food as consist chiefly of sugar.

SWEET PEA. See LATHYRUS.

SWEET POTATO. See BATATAS.

SWEETS, a term applied in England, and by the board of inland revenue, to home-made wines, for the sale of which a special license is granted. It is also a term in far more general use for lozenges, comfits, and other preparations of sugar well known to children; they are the *confitures* of the French.

SWEETSER, CHARLES HUMPHREYS, 1841-71; b. Mass.; graduated at Amherst, 1862; entered literary life, and was one of the founders of the *Round Table*, and of the *Evening Mail*, with which he was connected until 1869. He wrote a history of Amherst college, a collection of college songs, and an *Invalid's Guide to the North-west*.

SWEET SOP, *Anona squamosa*, a fruit of the same genus with the custard apple (q. v.). It is produced by a small bush, with lanceolate leaves, a native of the warm parts of America, and much cultivated in Brazil, the West Indies, and generally in tropical countries. The fruit is greenish, and resembles an artichoke in size, in form, and in its scaly covering. The pulp is soft, somewhat mealy, sweet, and luscious; with a musky aromatic odor and flavor. It is much used both in the East and West Indies, generally raw, but sometimes cooked. Notwithstanding its foreign origin, it has proved the staff of life to the people of Hindustan in seasons of famine. The seeds are acrid, and the powder of them is used to destroy insect vermin.

SWEETWATER, a co. in central Wyoming, having the territorial line of Montana for its n. boundary, and that of Colorado on the s., with a small portion of Utah; 35,000 sq. m.; pop. '80, 2,561—1445 of American birth, 542 colored. It is intersected in the s. by the Union Pacific railroad running through the coal region. It is drained by the river Big Horn in the n., the Green river in the s., and the Wind, Big Sandy, and Sweetwater rivers. The surface is mountainous, containing the Big Horn and Sweet-

water ranges of the Rocky mountains, and immense plains in the Wind river country are occupied by the Shoshone Indian reservation. Through the Wind river mountains, by Fremont's peak and the South pass, was formerly the only route from the Atlantic to the Pacific. The pass is 7,857 ft. above the level of the sea, several m. in width, and reached by a gradual ascent. Gold is found; also granite and iron ore; and in the co. are saw and grist mills. Co. seat, Queen River City.

SWEET WILLIAM. See PINK.

SWEET WOOD. See CASCARILLA.

SWELL, in music, a set of pipes in an organ with a separate keyboard, and forming a separate department, which are capable of being increased or diminished in intensity of sound by the action of a pedal on a series of shades or shutters overlapping each other like Venetian window-blinds, within which the pipes in question are inclosed. On a well-constructed swell, a practiced performer can imitate not only a gradual *crescendo* and *diminuendo*, but also a *sforzando*, a very small opening suffering to make an immediate burst on the ear; while, when the shutters are closed, an imitation of an echo is produced.

SWETCHINE, or **SVETCHIN**, ANNE SOPHIE, 1782-1857; b. Moscow; the daughter of Soimonoff, who was one of the founders of the academy of sciences at Moscow. She was brought up at the court of Catharine II., and in 1799 married gen. Swetchine. She gathered round her Russians and French emigrants of distinction, and her *salon* at St. Petersburg became very celebrated. In 1815 she was converted to Roman Catholicism, and then removed to Paris. After her death, her literary executor, De Falloux published *Mme. Swetchine, sa vie et ses œuvres* (1859); her *Lettres* (1862); *Journal de sa Conversion* (1863); and *Lettres inédites* (1866).

SWIETEN, GERARD VAN, 1700-72; b. Leyden, Holland; educated in his native place, and at Louvain; studied medicine at Leyden with Boerhaave, who obtained him the professorship of medicine in 1725. He was a Roman Catholic, and obliged for that reason to resign his chair. He was first physician to Maria Theresa of Austria, 1745, who made him a baron of the empire. By his influence the university was rebuilt, and a system of clinical instruction established at Vienna. He was opposed to the practice of vaccination. For 8 years he lectured on Boerhaave's *Institutes*, and adapted his system to that of his master; content to engraft the result of his own experience upon it instead of founding a school of his own. Besides his comments on Boerhaave, he wrote treatises on the diseases of armies and on epidemics. A statue to his memory was placed in the university by Maria Theresa.

SWIETENIA. See MAHOGANY.

SWIFT, *Cypselus*, a genus of birds of the swallow family. The distinctive characters of the group, of which the true swifts are the type, are noticed in the article SWALLOW. The swifts, like the swallows, are widely distributed, and some are only found in tropical countries; others are birds of passage, and spend the summer in colder parts of the world. Many of the swift group are often, popularly called swallows, as that which produces the edible nests of the East Indies. In the genus *Cypselus*, as now restricted, the tail is generally forked, the legs and toes feathered, and very small and weak, all the four toes directed forward. The birds of this genus pass most of their time in the air, and even copulate on the wing. The wings are longer than in any other bird; and the internal structure, even of the skeleton, is peculiarly adapted to prolonged flight. The anatomy more resembles that of humming-birds than of true swallows.—The COMMON SWIFT (*C. apus*) is common in almost all parts of the n. of Europe and of Asia in summer, retiring to tropical or subtropical regions in winter. It occurs even in Lapland. Its residence in its summer quarters is much shorter than that of swallows; and it is worthy of notice, that the swift is seldom to be seen along with any of the swallows or martins, the different kinds choosing different localities, even although very close together. The swift is easily recognized in its flight by the remarkably sickle-shaped wings, and its slight scream is very different from the twitter of the swallow. It is black, with a white throat. It makes its nest in holes of rocks or of walls, often in those of houses. The nest is formed of bits of straw, dry blades of grass, and bents, feathers, and other such substances, which are apparently glued together by a mucous secretion. The swift sometimes builds in hollow trees. Swifts, like swallows, seem to return to the same place to make their nest, year after year, and repair the old nest, instead of making a new one.—The ALPINE SWIFT, or WHITE-BELLIED SWIFT (*C. alpinus*), is rarely seen in Britain, but is common in the more southern countries of Europe. It builds in high rocks, sometimes in steeples. It is larger than the common swift, and is the largest of the British *Hirundinidae*. Its wings are even longer in proportion than those of the common swift. Its voice is sweet, not a scream like that of the common swift.—The AMERICAN SWIFT (*Chatura pelagica*) has the hind-toe directed backward, and the tail feathers stiff and pointed, as in woodpeckers. It is a small bird, not above 4½ in. in entire length, but 1 ft. in extent of wing. The general color is brownish black, with greenish reflections, the throat grayish white, the under parts grayish brown. The nest is made of small dry twigs, which the bird breaks off from the tree, and carries away in its feet; and they are attached by means of the saliva, to the rock, wall, or hollow tree where the nest is made. From its frequently building in chimneys, this species

is known as the *Chimney Swallow* in North America. Great numbers often build together, sometimes choosing for this purpose an unused chimney in a town.

SWIFT, a co. in w. Minnesota, drained by the Minnesota, Chippewa, and Pomme de Terre rivers; intersected by the St. Paul and Pacific railroad; about 850 sq.m.; pop. '80, 7,473—4,392 of American birth. The surface is mostly level, with little timber. The soil is extremely fertile. The principal production is wheat. Co. seat, Benson.

SWIFT, JONATHAN, the greatest of English satirists, and the most original writer of his age, was born in Dublin, but of English parents, on Nov. 30, 1667. He was a posthumous child, reared amid circumstances of abject poverty and dependence, the recollection of which galled his proud irascible spirit, and embittered much of his future existence. He was supported by relatives, and educated at Kilkenny school and Trinity college, Dublin. He proved a negligent and turbulent student, more intent on personal satires and political rhymes than academical honors: but he remained at college about seven years. He then removed to England, visited his mother in Leicestershire, and by her recommendation was admitted into the house of sir William Temple, who had long known the Swift family. He seems at first not to have conciliated the regard of the retired minister, for in the following year (May, 1690), Temple made an offer of the services of his protégé to sir Robert Southwell (then about to proceed to Ireland as secretary of state), recommending him as diligent and honest, qualified either to wait on sir Robert as a gentleman, or to write under him as a clerk. No appointment followed; Swift remained with Temple, studying hard, till 1694, when he went to Ireland, took orders in the church, and obtained a small living, which he threw up in two years, and returned to England, in consequence of Temple, who missed his society and assistance, urging him to come back. Temple died in 1698, and Swift in the following year, published his posthumous works, after which he again repaired to Ireland, obtaining from lord Berkeley some church preferments, including the vicarage of Laracor, worth in all about £400 per annum, which was all the professional income he enjoyed till he was appointed dean of St. Patrick's, in his 46th year. Before this, he had written the wildest and wittiest and most powerful satirical work of the 18th c., *The Tale of a Tub* (1704), also a few essays on ecclesiastical subjects, some inimitable ridicule of astrology under the name of Isaac Bickerstaff, and poetical pieces possessing a peculiar vein of humor and description. In 1710 he went over to the Tories, conceiving himself neglected by the Whig ministers, and exerted himself strenuously in behalf of his new allies, Harley and Bolingbroke. He wrote papers in *The Examiner* (1710); a *Letter to the October Club* (1711); *The Conduct of the Allies* (1712); *The Barrier Treaty* (1713), and innumerable pasquinades against the Whigs, whom he "libelled all round." He had become, as it were, a great and formidable power in the state, yet could extort no higher preferment for himself than the deanery of St. Patrick's. His party was overthrown by the death of queen Anne; and in 1714 Swift "commenced Irishman for life," with strong reluctance and disgust. In time, however, he took interest in Irish affairs, and identified himself with Irish feelings and prejudices. Hatred to Walpole and the English government quickened his activity; and his resistance to Wood's copper coinage—a scheme for supplying Ireland with copper money by an English patentee—raised him to the highest pinnacle of popular favor. His *Drapier Letters* (1724) produced quite a ferment in Ireland, and compelled the government to abandon the scheme of the coinage. Two rewards of £300 each had been offered for the unmasking of the Drapier, but not a traitor, as he says, could be found to sell him. The triumphant author made his last visit to England in 1726, and published his *Gulliver's Travels*, the most universally popular of all his works. He next joined with Pope, Arbuthnot, and Gay in publishing three volumes of *Miscellanies*, after which he returned to Ireland (Oct., 1727), and never left it again. He was subject to fits of giddiness and deafness, which increased in frequency and intensity as he grew old; he brooded over the anticipated madness which he foreboded would be his future lot; his temper, always irritable and gloomy, became more violent and morose, the effect of cerebral disease, and his memory and other faculties gave way. There was also a deep and secret grief; the fate of two ladies, known as Stella and Vanessa, had been inseparably entwined with his own destiny; both had sacrificed for him all but honor, and had sunk under disappointed hopes and blighted affection. We cannot here trace the painful story, which is still involved in mystery, but for a time the retribution of Swift was terrible. He rallied, however, and wrote some of his best minor pieces after this period. Among these are *The Grand Question Debated; On Poetry, a Rhapsody; The Legion Club; Verses on the Death of Dr. Swift*; and that extraordinary prose tract, *The Modest Proposal*, a masterpiece of irony, in which he proposes to relieve the distresses of the poor Irish by converting their children into food for the rich. The last three years of Swift's life were passed in almost total silence in the hands of keepers. He died Oct. 19, 1745.

It would be superfluous to attempt in our brief space to characterize the genius of the immortal dean of St. Patrick's. Shakespeare alone among English authors has received a greater amount of criticism and annotation. From Johnson to Thackeray, the most brilliant critics and biographers have employed themselves in elucidating his strange and sad history, and in estimating his writings. As a consummate master of ridicule and irony, possessing great powers of wit, invention, illustration, and analogy; possessing also the dramatic faculty that enabled him to assume and portray varieties of character;

and as writing a pure, perspicuous English style, unsurpassed for strength and simplicity, Swift must ever be a model in our language and literature. His misanthropy, or degradation of human nature—his Yahoos, Strulbrugs, daring irreverence, and indelicacy, are of course indefensible. He had a total incapacity, as De Quincey remarks, for “dealing with the grandeurs of the human spirit, with religion, with poetry, or even with science, when it rose above the mercenary practical.” His business was with the world—with the follies, vices, and absurdities of men. And his poetry is the same as his prose; it may come under his definition of a good style, “proper words in proper places,” applied to ordinary topics, but is wholly wanting in passion, elevated feeling, and imagination. A complete edition of his works, in 19 vols., was published by sir W. Scott (1815). See also Roscoe’s edition (1853), and *Life* (unfinished), by John Forster (1875).

SWIFT, JOSEPH GARDNER, LL.D., 1783–1865; b. Mass.; in 1802 graduated at West Point, the first graduate from the academy. He was commissioned in the engineers, rose to be chief of the corps with rank of colonel, and in the war of 1812 served on Pinckney’s staff and later had charge of the defenses of New York. In 1815 he was superintendent and inspector of West Point; resigned in 1818, and became surveyor of the port of New York. From 1829 to 1845 he was engaged in the harbor improvement of the great lakes, and in this period superintended the construction of the New Orleans and lake Pontchartrain railroad, a work of great difficulty on account of the swamps. In 1833 he was chief engineer of the New York and Harlem railroad.

SWIFT, WILLIAM H., b. Mass., 1800; educated at West Point. He joined Long’s Rocky mountain expedition in 1818, and was on topographical duty, 1821–32, making surveys on the Chesapeake and Ohio canal, the Florida canal, and several railroads. For the ten years from 1832 he was attached to the geodetic survey of the Atlantic coast, supervising the river and harbor improvements, 1837–42. He was also constructing engineer of the Western railroad in Massachusetts, 1836–40. He supervised the construction of the Minot’s ledge light-house, 1847–49. Resigning from the army in 1849, he became president of the Philadelphia, Wilmington and Baltimore railroad, and afterward of the Western railroad, and the Illinois and Michigan canal.

SWILLY, LOUGH, an inlet of the Atlantic on the n. coast of Ireland, in the county of Donegal, enters between Dunaff head on the e., and Fanad point, on which there is a light-house, on the west. It penetrates the country in an irregular, but generally s. direction, is about 25 m. in length, and at its entrance, where it is widest, it is $3\frac{1}{2}$ m. broad. On the eastern shore is the small town of Buncrana, much resorted to for sea-bathing; and in front of which is a roadstead, capable of accommodating the largest men-of-war.

SWIMMING. The art of swimming is so exceedingly useful, not only as a bracing summer exercise, but as a means of preserving life, that it should be acquired by every young person. Considering the numerous risks run by all human beings, especially by the inhabitants of maritime countries, of being accidentally plunged into the water; and how greatly the chances of being saved are increased by the power of keeping one’s self afloat for even five minutes, it is surprising that the art of swimming does not form an essential element of education among all classes. With our limited space it would be needless to attempt giving directions that would be of any practical value. In many cities there are now swimming-schools, where professional instruction may be had. When these are not available, any acquaintance who can swim will give his aid until the elementary movements and the necessary confidence are acquired. Even without help, by keeping in safe water, and by perseverance, the art will be acquired as by instinct.—See Chambers’s *Information for the People*—“Out-of-door Amusements;” Routledge’s *Hand-book of Swimming and Skating*; and *The Boy’s Own Book*.

SWINBURNE, ALGERNON CHARLES, one of the first of living English poets, is the son of admiral Charles Henry Swinburne, by lady Jane Henrietta, daughter of the third earl of Ashburnham, and was born in London on April 5, 1837. He entered as a commoner at Balliol college, Oxford, in 1857, but left the university without graduating. His first literary venture, a volume published in 1861, containing two plays, *The Queen Mother* and *Rosamund*, attracted little attention; but *Atlanta in Calydon*, a tragedy, which appeared in 1865, at once established his reputation. Afterward came *Chastelard*, a tragedy (1865); *Poems and Ballads* (1866); *A Song of Italy* (1867); *Siena* (1868); *Songs before Sunrise* (1871); *Bothwell*, a tragedy (1874); *Erechtheus* (1875); and a new series of *Poems and Ballads* in 1878. Swinburne belongs to what has been aptly called the “fleshy school” of poetry, and even those who most admire his power of poetical expression, richness of coloring, and happy lyrical effects must deplore the sensuous tone of his muse. He has also been severely animadverted upon for the wanton violence with which he attacks the most sacred beliefs of his fellow-men. Swinburne is well known in the department of poetical criticism. A collection of his *Essays and Studies* was published in 1875; his *Note on Charlotte Brontë* in 1877.

SWINDON, an old market-t. of Wilts, 77 m. w. of London by the Great Western railway. It contains a handsome church, large corn-exchange, and excellent shops. About a mile n. of the town is Swindon junction, the great central establishment and manufactory of the Great Western railway company.

A considerable town has risen around the station, called the New Town, and consisting for the most part of dwellings for the employees of the railway. There are also a large and remarkably beautiful church, a public park, library, and mechanics' institution. Pop. of Old Town, '71, 4,092; of New Town, 7,628.

SWINE. See Hog, *ante*.

SWINE-PLAGUE, or HOG CHOLERA, an infectious disease produced by a bacteroid schizophyte, a microscopic organism having the power of indefinite multiplication in the system. The symptoms and pathological conditions vary considerably, depending upon the virulence of the disease, this depending very greatly upon the number of animals kept together, crowding greatly aggravating the disease. At the commencement of the attack the animal is generally seized with a shivering, which may last from a few minutes to several hours. There is also frequent sneezing and more or less coughing. The temperature of the body is also increased, ranging from 104° to 106° Fahr. but this symptom is variable, and not to be relied upon; and it is difficult to ascertain the temperature of a hog. The shivering, coughing, and sneezing are soon followed by loss of appetite and the rough appearance of the coat. Drooping of the ears is characteristic, and sometimes the animal attempts to vomit. Swelling of the head often takes place, and eruptions appear on the ears and other parts of the body. There is frequently bleeding from the nose, swelling of the eyelids and partial or total blindness, accelerated breathing; sometimes constipation, and sometimes diarrhea. There is rapid emaciation, and a vitiated appetite for dung and dirt, and a peculiar, offensive odor to the exhalations which is characteristic. This odor is so penetrating as to be observed in a large herd at the distance of half a mile. On examining the chest by auscultation a rubbing sound is heard which indicates inflammation of the pleural membrane. Sometimes there is extensive ulceration and sloughing of the snout and gums. If the subjects have been recently ringed with wire in the nose, the wounds thus made have a great tendency to ulcerate, and the disease may be communicated through wounds or abrasions of any kind. Post mortem examinations reveal more or less hepatization of the lungs, with accumulation of blood, serum, and exudation in the lung tissue. Sometimes the solidification from hepatization is sufficient to cause the lung to sink in water. Sometimes the hepatization occurs only in isolated places, but sometimes extends over the whole lung. Gray and red hepatization may exist side by side. The lymphatic and mesenteric glands are always more or less enlarged. There is generally more or less exudation of plastic material, and more or less adhesion between the lung and the walls of the chest. Sometimes the adhesion involves the whole lung. The heart is generally more or less affected. Sometimes it is flabby and dilated, but more frequently congested, the capillaries, particularly of the auricles, being gorged with blood. Nearly all cases present characteristic morbid changes in the upper part of the large intestine, consisting of ulcerous tumors of the mucous membrane, varying in size from a pin's head to that of a quarter of a dollar. The other intestines are similarly affected, although in a less degree. Ulcerous tumors are also sometimes found upon the gall bladder and upon the mucous membrane of the stomach. The serous membrane of the abdominal cavity is also inflamed, so that there will be adhesions between different parts of the intestines, or between them and the peritoneal lining of the abdominal walls. Indeed, in the worst cases, it may be said that scarcely an organ escapes sufficiently not to exhibit lesions visible to the naked eye. A microscopic examination of the blood, or blood serum, or exudations, reveals great numbers of schizophytes in various stages of formation, some in separate minute globules, of micrococcus stage, some in aggregated masses, and some in bacillus rods. The disease is communicable to other animals by inoculation, and rats may contract it and cause it to spread. Dogs appear to have but little susceptibility, but do sometimes contract the disease. The extreme cold of winter checks the spread of the complaint, but the disease germs, or schizophytes, are not killed by it, although the thermometer may mark 30° below zero. The above information is chiefly taken from the reports of Dr. H. J. Detmers of Chicago to the governmental agricultural bureau at Washington; and the following is from a paper read before the state microscopical society of Illinois, April 8, and published in *Science* of May 7, 1881: "1. It has been and can be everywhere observed, where swine-plague is prevailing, that the infectious principle floating in the air is attracted and taken up by sores, wounds, and even scratches, but does not enter the animal organism through the whole skin and through perfectly healthy respiratory mucous membranes. 2. Antiseptics, or medicines which are either directly poisonous to the lower forms of organic life or destructive to those conditions under which low forms of organic life thrive and develop, and among those antiseptics, especially carbolic acid, iodine, hyposulphite of soda, benzoate of soda, thymol, etc., have proved to constitute almost sure prophylactics. . . . Further, the various antiseptics which have proved to be good prophylactics are very dissimilar in their chemical affinities and actions, and their prophylactic effect cannot very well be explained if the infectious principle were a chemical agency, a virus, or a poison, but is explained if the same consist in something endowed with life and power of propagation. . . . 6. If the cause and infectious principle of the swine plague were a chemical poison or virus, one would suppose a cessation of the morbid process would be impossible, and an animal would never recover while its organism contained an abundance of the infectious principle in an effective

condition, as is undoubtedly the case, because convalescents and animals nearly recovered frequently communicate the disease, even in a fatal form, to other healthy pigs. Further, the fact that an animal, once recovered, possesses but little predisposition for future infection, or is seldom attacked a second time, even if ever so much exposed, and then only contracts the disease in a comparatively mild form, could never be explained; but the whole presents an entirely different aspect, and admits of explanation if low and minute forms of organic life, such as the schizophytes of swine-plague, which by developing and multiplying finally destroy or exhaust in an animal organism the conditions necessary to future development and propagation, constitute the cause and the infectious principle." Dr. Detmers says that the swine-plague schizophytes, although having the same general characteristics when cultivated in fluids artificially as when developed in the animal, have less uniformity in size and develop rather slower. He concludes that they are less vigorous; and therefore when an animal is inoculated with them the disease produced is milder than when propagated in the ordinary manner, or by material taken from the body of a diseased hog. Sometimes, however, owing to other circumstances, inoculation with cultivated schizophytes produces a virulent form of the disease. In regard to prevention, Dr. Detmers, in his report to the commissioner of agriculture, July, 1879, takes the ground that measures of extermination must be thorough. He advises: 1, "that a competent and reliable person be appointed in every county, or where a great many hogs are raised, and where the country is thickly settled, in every township, with authority to institute, superintend, and enforce a strict execution of such measures of extinction and prevention as may be authorized by law; 2, that every owner of hogs or pigs must be compelled by law to inform the above officer, say within 12 hours after the occurrence, of every case of swine-plague in his herd, or any herd, that may come to his knowledge; 3, that every hog or pig showing symptoms of swine-plague must be immediately destroyed and buried from 4 to 6 ft. deep, or cremated, and that all exposed hogs be kept under quarantine for several weeks or killed; 4, that all infected premises be thoroughly cleaned and disinfected, and remain unoccupied for six weeks or two months; 5, that no hog or pig be allowed to run at large or to have access to running water if swine-plague has made its appearance within 10 m.; 6, that railroad companies and other public carriers be forbidden to receive and load hogs from any township or county after having been notified by the proper officer that swine-plague is there existing, except by special permit of such officer, and various other restrictions. The treatment most relied on is good care, uncontaminated and pure food and water, perfect cleanliness, and separation from sick animals and all other sources of infection. Medicines avail but little, and patent quack nostrums are a curse."

SWINEMÜNDE, a maritime and fortified t. of Prussia, province of Pommern, is situated on the island of Usedom, at the entrance of the narrow channel of Swine, which connects the Grosses Haff (into which the Oder flows) with the Baltic. Swinemünde as in some sense the port of Stettin (q.v.), carries on a considerable commerce, and has also valuable fisheries, but it is chiefly noted for its excellent sea-bathing, for which it is much frequented. Swinemünde has regular steam-communication with Stettin (daily), Rügen, and Copenhagen. The light-house of Swinemünde is the loftiest in the world, being 210 feet high. Pop. of Swinemünde '75, 8,045.

SWING, a cognomen assumed by senders of threatening letters during the period when the irritation of the agricultural laborers of England against their employers was at its height—viz., from 1830 to 1833. The cause of this misunderstanding arose from a widespread belief on the part of the laborers, that the use of machinery would greatly lessen the demand for labor, and consequently produce a general reduction of wages; it was also intensified by the savage severity with which the game-laws were enforced, and by other hardships to which the laboring-classes in the country considered themselves unjustly subjected. As any inattention on the part of landlords or farmers to the demands contained in these threatening letters was almost invariably followed by the burning of stacks, farm-buildings, etc., the employers of labor became so terrified that implicit obedience was paid to the dictates of "captain Swing." It is not to be wondered at that, with such encouragement, "swings" became numerous, and their demands more insolent; but the apprehension and punishment of a number of them gradually brought about a cessation of the outrages.

SWINTON, WILLIAM, b. Edinburgh, 1833; removed to the United States when ten years old, and pursued his studies at Amherst college. In 1853 he was a teacher in a female academy in Goldsborough, N. C.; but soon after settled in New York, where he devoted himself to study, and to making translations from the French, the most important being that of Rousseau's *Confessions*. On the outbreak of the rebellion he was sent to the front as war-correspondent for the *New York Times*, and served principally with the army of the Potomac, of whose career he was afterward a historian. Soon after the war he was appointed professor of *belles-lettres* in the university of California at Oakland. Of late years he has devoted himself to writing educational works. He has published *Rambles among Words*; *Campaigns of the Army of the Potomac*; *The Twelve Decisive Battles of the War*; and geographies, grammars, and reading-books.

SWISS GUARDS, first employed in the French service in 1616. It was the policy of the royal family to render these guards personally faithful to themselves, and to

Surface.—Switzerland is the most mountainous country of Europe. Its principal chains are the Alps (q.v.) and the Jura (q.v.). The former run from e. to w. along its southern or Italian frontier. Their ramifications fill more than one-half of the country, and terminate along a line which may be traced from Vevey, on the lake of Geneva, to mount Moleson and mount Napf, across lake Zug, to the southern shores of the lakes of Zürich and Wallenstadt, and Sargans on the Rhine. The mean elevation of the highest chain is from 8,000 to 9,000 feet. The Jura run n.e. from the western corner of Switzerland. They consist of a series of parallel ridges inclosing long and narrow valleys, and their mean elevation does not exceed 4,000 feet. In the angle formed between them and the Alps lies the plain of Switzerland, a table-land 100 m. in length, and from 20 to 30 m. in width, with a mean elevation of about 1400 ft. above the sea. It is not absolutely level, but covered with elevations, which seem very unimportant, however, when contrasted with the huge masses of the Alps and Jura. It has been described, and not inaptly, as a corner of southern Germany, penetrating like a wedge between France and Italy. The communication between the plain of Switzerland and the German valleys of the Danube and Rhine is not, however, continuous. The plain on the e. terminates in a third hilly tract—the Thur hill-country, which lies between the lakes of Zürich and Constance, and which, to some extent at least, forms a barrier between the plain of Switzerland and Germany. The Jura, the plain, and the hill-country are, then, the great divisions of northern Switzerland. The divisions of the Alpine region are more strongly marked in nature. A glance at the map will show that the chains which overspread it radiate from a mountain knot lying to the w. of the Grimsel pass. They isolate and inclose (1) the valleys drained by the Rhone, which connect Switzerland with southern France; (2) Ticino, drained by streams which descend to the Po, and have at all times brought this country into close communication with Italy; (3) The Grisons, the most sequestered valleys of Switzerland, drained by the tributaries of the Rhine and Danube, and shut out by mountains from the lower basins of these rivers; (4) The Bernese Oberland, which slopes toward the western extremity of the Swiss plain; (5) The district of the forest cantons—Schwyz, Uri, and Unterwalden—surrounding the lake of Lucerne, and which slope toward the eastern extremity of the plain, and seem a great mountain fortress erected in the very heart of Switzerland, to protect the plain against German invasion.

Geology is of little importance in explaining the general geography of Switzerland. It may, however, be stated that in the southern Alpine region the rocks are crystalline; that in the northern Alpine region they belong to the jurassic and other upper secondary strata; and that in the plain and the great part of the hill-country they consist of loose tertiary sands and clays, which supply the best agricultural soils of Switzerland. Those rocks and formations in which mines and coal chiefly abound are absent.

Climate.—In Switzerland the climate chiefly varies with elevation above the sea-level. At a height exceeding 9,500 ft., the mountains are covered with perpetual snow, which descends along the hollows in glaciers (q.v.) to a much lower level, and in this way covers the elevated part of the country with a vast sea of ice. Below the level of perpetual snow, the surface of Switzerland has been divided into a series of belts, characterized by different climates and productions. The highest of these, lying between the snow and the level of 6,900 ft., has been called the upper Alpine region. In it the glaciers fill the valleys, but plants clothe the scanty soil of the ridges. The second or lower Alpine belt descends to 4,800 feet. It is a country of pastures, in which shrubs but no trees make their appearance. The Righi pass, the Grimsel hospice, and the Splügen are included in it. The third belt descends to 4,350 feet. The meadows still abound in it, but forests of firs and maples in many parts replace them. It includes Urftenthal and Oberengadin. The fourth belt sinks to 3,000 feet. The forests still abound, the beech being the prevailing tree. The meadows are excellent, and rye and barley are successfully cultivated. It includes Weissenstein, Grindelwald, and Engelsberg. The fifth belt lies above 1800 feet. In it the oak and walnut are the characteristic forest trees. Spelt and the best wheat are cultivated. It includes Bern, Coire, and St. Gall. The last belt sinks to 750 feet. In it the chestnut is the characteristic tree; the mulberry and the vine are extensively cultivated, and wheat is the grain chiefly grown. This belt includes the greater part of the Swiss plain, and sinks to its lowest level in the valley of the Rhine, between Constance and Basel, and the banks of lake Zürich and the lago Maggiore. In the last district the vegetation is that of northern Italy. At a higher elevation than 6,400 ft., Switzerland is only inhabited by herdsmen during the summer months. At this limit, however, permanent abodes begin to make their appearance; and at 4,000 ft. there are many villages. The most populous part of Switzerland, however, lies between 1250 and 2,150 feet. The temperature of this region is fairly represented by that of Zürich, which we will compare with that of London. The temperature of Zürich is in winter 30.34°; in spring, 47.25°; in summer, 64.15°; in autumn, 49.05°; for the year, 47.95°. The temperature of London is in winter, 38.22°; in spring, 48.34; in summer, 61.74°; in autumn, 50.29°; for the year, 50.50°.

Productions.—In Switzerland, where good coal is not to be had, and where the houses are built of wood, the forests, which cover one-sixth of the whole surface, acquire very great importance. Wood-cutting is one of the chief employments of the people. The trees cut down in the highlands are deprived of their branches, and shot with inconceiv-

able rapidity over the slopes to the valleys below, whence they are removed by rafts, not only to different parts of Switzerland, but to France and Germany. It is, however, the mountain-pastures and the meadows, forming two-fifths of the whole surface of the country, that supply the chief occupations of the people—those of herdsmen and shepherds. During the summer the cattle are driven into the mountains, and tended by herdsmen, who take up their abode in the rude wooden huts known as *châlets*, and there the butter and cheese are made. In summer it is estimated that there are in Switzerland upward of a million of horned cattle, one-fourth of which consists of milch cows. The produce of the dairy annually is valued at between one and two millions sterling. The best breeds of cattle are those of Saanen and Simmenthal in Bern, Gruyères in Freiburg, Schwyz, Zug, Entlebuch, Pralligau in the Grisons, and Glarus. The best cheese is made at Emmen, Saanen, Simmenthal, Gruyères, and Ursern. The sheep of Switzerland are of inferior breed, and their wool is short and coarse; but the goats are numerous and fine. More than two-thirds of Switzerland does not supply corn enough to feed its inhabitants. The plain, however, is a fertile agricultural country. In Vaud and Neuchâtel the cultivation of the vine is the chief occupation of the people; and in the Thur hill-country, more particularly on the shores of the lake of Constance, there are extensive orchards, in which are prepared cider and *kirschwasser*, the latter being a liquor largely consumed in Switzerland. It will give some idea of the extent to which Switzerland is cultivated to state, that out of every 100 sq.m. of surface, 30 are occupied by rocks, glaciers, and water; 20 by hill-pastures; 17 by forests; 11 by arable lands; 20 by meadows; and 1 by vineyards. In the uncultivated part of the country the bear, the wolf, and the larger birds of prey are still met with; and the chamois (q.v.) is hunted. The rivers and lakes abound with fine fish, and more especially with trout.

Manufactures.—The manufacturing districts are not scattered over the whole surface of the country; they are met with only on the northern frontier. The chief manufactures are: at Zürich, silk-stuffs, to the value of £1,600,000 annually, and cottons; at St. Gall and Appenzell, cottons; in Aargau and Glarus, cottons, linens, silks, and hosiery; at Basel, silk-stuffs to the value of £1,400,000, leather, paper, and tobacco; in Aargau and Lucerne, straw-plaiting; in Neuchâtel, watch-making and cotton printing; in Geneva, watch-making and jewelry. Although Switzerland is inland, its commerce in proportion to population has long exceeded that of any other continental country. The chief imports are corn, salt, salt-fish, raw silks, and cotton, fruits and tropical produce, and the metals employed in watch-making. The exports are wood and charcoal, cattle, tallow, cheese and butter, silks and cottons, watches and jewelry. Internal communication has long been facilitated in Switzerland by excellent roads, and every advantage has been taken of the lakes to introduce steam-navigation. The plain is now overspread from one end to the other with a network of railways, which in many directions send ramifications into the Alpine valleys, thus connecting closely all parts of the country.

Government.—Hitherto, the Swiss have been very much split into distinct communities by the great mountain-chains which separate the cantons. One of the results has been the weakness of the central power. Each valley has been intrusted with the making of its own laws, and the management of its own local affairs. The cantons are, in fact, to this day in a great measure separate states. They are divided into two classes, absolute democracies and representative democracies. In the former the chief power belongs to the *landesgemeinde*, an assembly of the whole adult male population, which meets once a year, to pass laws, and to regulate the taxes and expenditure of the canton. Uri, the Unterwaldens, Appenzell, and Glarus have constitutions of this kind. In the Grisons and the Valais, the people may be said to possess similar powers, as all measures must be approved of by them. In the other, the representative cantons, a great council is elected by the people, and to it are deputed most of the powers of the *landesgemeinde*. These local assemblies produce a remarkable effect on the Swiss people. Their debates have an importance far beyond that of an English town-council, or even of a colonial parliament, for their power is infinitely greater, and the population are more immediately interested in them. To the interest they excite is no doubt to be attributed in a great degree the intelligence and public spirit of the Swiss. Their greatest disadvantage lay in the power they formerly had to levy war against each other, and to resist the general government in conducting the foreign policy of the country. But these defects have been to a great extent remedied by the constitution of 1848, which forms the basis of the present constitution, which dates from 1874. It handed over the control of the army, the conduct of foreign affairs, the settlement of disputes between the cantons, and the management of the police and post-office, to a federal assembly (*bundesversammlung*) representing all the cantons. How far this assembly is entitled to interfere with the legislative action of the cantons, has not been very distinctly defined, but the tendency of legislation since its formation has been rather to trench than otherwise on their prerogatives. The federal assembly consists of two chambers—1st, the state council (*ständerath*); 2d, the national council (*nationalrath*). The former is composed of 44 members, 2 representing each canton; the latter, of 135 members, elected by the cantons in the proportion of 1 to 20,000 inhabitants. These bodies depute the executive authority to the federal council (*bundesrath*), consisting of seven members, and holding office for three years. The president is

merely one of the council, and he has none of the quasi-royal privileges of the American president. There is also a court called the federal tribune (*bundes gericht*), which acts as a high court of appeal, and consists of 9 members elected by the federal assembly. Different systems of law still prevail in the different cantons, which to some extent resemble each other, the most of them having grown out of the old German codes. Except in a few frontier cantons, the Roman law has not been much regarded. Until 1874 the law of the Catholic cantons prescribed, for certain offenses, various degrees of corporal punishment, exposure on the pillory, and public penance in the churches; but in that year capital and corporal punishment was abolished throughout the confederation. In Switzerland property is much subdivided; of 485,000 heads of families, no less than 465,000 possess landed property. In the absence of great landed estates there is no powerful aristocratic class. There are no titles of Swiss origin, families possessing such distinctions deriving them from abroad.

There is no standing army in Switzerland, but every citizen is obliged to serve as a soldier, and military drill is taught at all the schools. The Swiss regular force numbers 120,000; the reserve 92,000. The whole expense of the military establishment was, in 1878, estimated at 13,298,367 francs. The estimated national revenues amounted (1878) to 40,442,000 francs, and the expenditure to 42,818,000 francs.

Language and Religion.—In the sequestered valleys of the Grisons, two-thirds of the population still speak a Latin dialect known as the Romansh; Italian dialects have penetrated up the valleys of Ticino; French patois has invaded western Switzerland by the Rhine and the valleys of the Jura, to Laufen, the frontier of Soleure, lake Morat, the Upper Saane, and Siders in the Valais. In the rest of Switzerland the dialects are German. Of every 1000 Swiss, 702 speak German, 226 French, 55 Italian, and 17 Romansh. The Swiss reformation spread chiefly from Basel, Bern, and Geneva, and the chief Protestant districts are the countries communicating with these towns. The Alpine region is almost entirely Roman Catholic, the seven Catholic cantons being Lucerne, Zug, Schwyz, Uri, Unterwalden, Valais, and Ticino. Out of 1000 Swiss, 411 are Roman Catholics, 587 Protestants, and 2 Jews.

Education.—In no country is elementary instruction more widely diffused. Parents are compelled to send their children to school, or have them privately taught from six to twelve. There are universities on the German model at Basel, Bern, and Zurich, and academies on the French plan at Geneva and Lausanne. The number of clubs for scientific and literary, musical and social purposes, is most remarkable. There are no pursuits to which a class of men can devote themselves which are not represented by societies in Switzerland. The local political assemblies and other public meetings give ample employment to the newspaper and periodical press. In Switzerland there are accordingly 188 political journals, and 167 periodicals devoted to literature and science. There are 40 daily papers. This active intellectual life is, however, chiefly confined to the Protestant cantons.

History.—Switzerland was in Roman times inhabited by two races—the Helvetii, supposed to have been Celts, on the north-west; and the Rhetians (of whose origin we know nothing) on the south-east. After the conquest of Gaul, both races adopted the language and habits of Rome. When the invasions took place, the Burgundians settled in western Switzerland; while the Alemanni, another Germanic tribe, took possession of the country east of the Aar. A third Teutonic people, the Goths, entered the country from Italy, and took possession of the country of the Rhetians, which nearly corresponded with the Grisons. The Burgundians adopted Christianity in the end of the 5th c.; the Helvetii retained their old pagan creed until the 7th c., when they were converted by Irish monks, who founded abbeys and churches, which survive to our own time. Switzerland, in the early part of the middle ages, formed part of the German empire, and feudalism sprang up in the Swiss highlands even more vigorously than it did elsewhere. During the 11th and 12th centuries, the greater part of Switzerland was ruled on behalf of the emperors by the lords of Zähringen (q. v.), who did much to check civil wars, and to promote the prosperity of the towns. They, however, became extinct in 1218, and then the country was distracted by wars which broke out among the leading families. The great towns united in self-defense, and many of them obtained imperial charters. In 1273, Rudolf of Hapsburg, a Swiss nobleman who had favored the independence of the towns, became emperor. After doing so, he continued the same policy; but his son, Albert I. (q. v.), took another course. He attacked the great towns and was defeated. The leading men of the forest cantons, which for ages had yielded a merely nominal recognition of the empire, and had acknowledged no feudal superior, met on the Rütli meadow, on Nov. 7, 1307, and resolved to expel the Austrian bailiffs or landvögte. See TELL. The war terminated in favor of the Swiss at Morgarten in 1315. Schwyz, Uri, and Unterwalden, with Lucerne, Zürich, Glarus, Zug, and Bern, eight cantons in all, in 1352, entered into a perpetual league, which was the foundation of the Swiss confederation. Other wars with Austria followed, which terminated favorably for the confederates at Näfels (q. v.) and Sempach (q. v.). In 1415, the people of the cantons became the aggressors. They invaded Aargau and Thurgau, parts of the Austrian territory, and annexed them; three years later, they crossed the Alps and annexed Ticino, and constituted all three subject states. The Swiss were next engaged in a struggle on the French frontier with Charles the

hold of Burgundy. They entered the field with 34,000 men, to oppose an army of 60,000, and yet they were successful, gaining the famous battles of Granson and Morat in 1476. In 1481 the towns of Freiburg and Soleure were admitted into the confederacy. In 1499 the emperor Maximilian I. made a final attempt to bring Switzerland once more within the bounds of the empire. He sought to draw men and supplies from the inhabitants for his Turkish war; but in vain. He was defeated in six desperate engagements. Basel and Schaffhausen (1501), and Appenzell (1513), were then received into the confederation, and its true independence began. The abbacy of St. Gall, the cities of St. Gall, Mühlhausen, and Bienne became associated states with a vote at the diet. Geneva, Neuchâtel, Valais, and the Grisons, also became associated states, but without a vote.

New troubles sprang up with the reformation. Zwingli began to preach in the beginning of the century, and Zürich, in 1523, adopted his opinions, and was followed by Bern and other cantons of the north. The forest cantons remained attached to the church of Rome. War broke out in 1531 between the Catholics and Protestants, and the former were successful at Cappel, where Zwingli was slain. This victory to some extent settled the boundaries of the two creeds in eastern Switzerland. In 1536, however, Bern wrested the Pays de Vaud from the dukes of Savoy and annexed it to their own territory. In the same year Calvin settled at Geneva, and the reformed doctrines spread throughout western Switzerland. During the thirty years' war Bern, which had become, since the conquest of Vaud, the leading canton, and Zürich, contrived to maintain with great skill the neutrality of Switzerland; and in the treaty of Westphalia, in 1648, it was acknowledged by the great powers as a separate and independent state. At this period the Swiss, in immense numbers, were employed as soldiers in foreign service, and the record of their exploits gives ample evidence of their courage and hardihood. Internally there was great stagnation. The constitution of the larger cantons became more aristocratic, that is to say, the mass of the people lost their power over the governing bodies. In Zürich, Schaffhausen, and Basel the governing councils were elected by the corporations; and in Bern, Freiburg, Soleure, and Lucerne, a few families had acquired permanent rule. At the end of last century there was widespread discontent with this state of matters; but the French revolution broke out, and wars followed, which left no time for its manifestation. In 1798 Switzerland was seized by the French. At the peace of 1815 its independence was again acknowledged. The new confederation was divided into 22 cantons, each of which was represented in a diet, which was appointed to hold its annual meetings alternately at Bern, Zürich, and Lucerne. The old abuses which had crept into the constitutions of the cantons were revived, and representation in most of them became based on property qualifications. Officials, the aristocracy, and the clergy joined to oppose innovations, and succeeded in doing so until 1830, when the French revolution broke out. Armed demonstrations were made against the towns, and universal suffrage was generally conceded. Basel town, however, held out; but the difficulty was settled by the separation of the town and country districts—the former remaining conservative, the latter becoming democratic. Geneva and Neuchâtel retained their old constitutions. The result of the changes was, however, that two-thirds of the whole population were allowed to take part in public affairs. The consequences were not what had been expected by the liberals, who found that they had not yet the means of strengthening the central power. In 1839 at Zürich, where Dr. Strauss had been appointed a professor of theology, a mob of peasants, headed by the Protestant clergy, overturned the government. In Aargau a struggle took place between the liberals and the Ultramontane party, which was settled, after long discussion, by an unsatisfactory compromise. In Valais, where universal suffrage had put power into the hands of the reactionary party, a war took place, in which the latter were victorious. They then ruled with a strong hand, and actually forbade the celebration of Protestant worship within the canton. In Lucerne, the headquarters of the Jesuits, the Ultramontane party acted even more extravagantly; they so persecuted their political opponents that the latter were compelled to leave the canton. These measures caused the greatest discontent. In 1844 a proposal was made in the diet to expel the Jesuits; but that body declined to act. The radical party then determined to resort to force; they organized bodies of armed men, called the free corps, which invaded the Catholic cantons, but they were defeated. Changes favorable to them took place in some of the cantons. The Catholic cantons then formed a league, named the Sonderbund, for defense against the free corps. There was a general clamor for its suppression, but in the diet only 10½ votes were in favor of that measure. The ruling party in Geneva had been with the majority, and this conduct led to a revolution in that city. One vote was thus gained against the Sonderbund. St. Gall added another; and a majority in the diet in 1847 declared the illegality of the Sonderbund, and decreed the expulsion of the Jesuits. In the war which ensued between the federal army and the forces of the Sonderbund, the former were victorious at Freiburg and Lucerne. The leagued cantons were made liable in all the expenses of the war, the Jesuits were expelled, and the monasteries were suppressed. An attempt was made by diplomatic notes to intimidate the Swiss government, but the revolution of 1848 broke out and prevented further interference. In the same year the radical party, convinced of the necessity of a more powerful central government, carried the constitution of 1848, of which we have already taken notice. Since

then the most important event which has taken place in Switzerland was a rebellion against the king of Prussia as prince of Neuchâtel. The canton was declared a republic, with a constitution similar to that of the other Swiss states. The king of Prussia protested, but in vain, against the change, and at length he withdrew all opposition, and remained satisfied with the bare title of prince of Neuchâtel, which he still retains.

SWITZERLAND, a co. in s.e. Indiana, adjoining Kentucky; bounded e. and s. by the Ohio river; about 250 sq. m.; pop. '80, 13,336—12,950 of American birth. The surface is hilly, except along the river. There are extensive forests. The soil is fertile. Corn, wheat, oats, grass, and live stock are the principal productions. Co. seat, Vevay.

SWIVEL is a gun constructed, as regards its carriage, to turn on a pivot, or on two concentric iron rails. Its use is on shipboard or in a fortress.

SWORD, a well-known weapon of war, the introduction of which dates beyond the ken of history. It may be defined as a blade of steel, having one or two edges, set in a hilt, and used with a motion of the whole arm. Damascus and Toledo blades have been brought to such perfection that the point can be made to touch the hilt and to fly back to its former position. In last century, every gentleman wore a sword; now the use of the weapon is almost confined to purposes of war. In the British army, all officers and sergeants, with troopers of cavalry, wear swords for cutting and thrusting. In the navy, all officers wear similar swords; and the men in time of action, heavy-backed swords, called *cutlasses*. In the French service, nearly all troops wear a combination of the sword with the bayonet, called a sword-bayonet.—For various sorts of swords and their uses, see **RAPIER**, **CUTLASS**, **BROADSWORD**, **SCIMITER**, **SABER**, etc.: **FENCING**.

SWORD-FISH, *Xiphias*, a genus of fishes of the family *scomberida*, having the upper jaw remarkably elongated and compressed, in the form of a sword or dagger. The body is rather of a long shape, and covered with very small scales. There are no teeth. There is one long dorsal fin. There are no finlets. The ventral fins are wanting. The sides of the tail are very strongly keeled. The tail-fin is large and forked. Only one species is known, *X. gladius*, plentiful in the Mediterranean, and in the warmer parts of the Atlantic; sometimes, but rarely, seen on the British coasts. It is bluish black above, and silvery white on the belly, the one color passing gradually into the other. It is highly esteemed as an article for food, especially when young. It is harpooned by the fishermen of the Mediterranean, and is powerful enough to drag a boat about for many hours after being struck. It has been said to attack the whale with its sword, but this is extremely improbable. Its food consists in great part of squids and cuttle-fish. The use of the sword is unknown. Instances not unfrequently occur of ships' bottoms being perforated by the sword of the sword-fish, but there is no good reason to think that an intentional attack is ever made.—Other species of sword-fish, belonging to genera closely allied to *xiphias*, are found in the seas of different parts of the world.

SYBARIS, and **CROTON** or **CROTONA**, two celebrated Greek colonies in Magna Græcia (q.v.). The former—founded 720 b.c., by Achæans and Trezenians—was situated in the s. of the Lucanian territory, between the rivers Crathis (*Crathis*) and Sybaris (*Coscila*) about 3 m. from the Tarentine gulf; and the latter—founded 710 b.c., by Achæans—about 50 m. s.e. on the coast of Bruttium. All that is certainly known concerning these cities before the destruction of the former is, that they both rapidly increased in size, wealth, and power, extending their dominions across the peninsula, and founding other colonies, at the same time preserving the most friendly terms with each other. Sybaris is said to have been 6 m. in circumference, and Croton 12 m.; the former being notorious for the excessive and fastidious luxury of its inhabitants (hence the term Sybarite), and the Crotoniates celebrated for the perfection they reached in athletic exercises—the famous athlete, Milo (q.v.), having been a native of Croton. Somewhere between 540 and 530 b.c., Pythagoras (q.v.) settled at Croton, and exercised very considerable influence over the aristocratic government. About 510 b.c. a democratic leader, Telys, deposed the oligarchy of Sybaris, banished 500 of the leading citizens, and assumed the tyranny of the city. The banished citizens having taken refuge in Croton, Telys demanded their surrender, and on being refused, declared war against that city. The Sybarites, with an army said to have amounted to 300,000, met 100,000 Crotoniates, commanded by Milo, at the river Traeis, were completely routed, and their city obliterated by the latter changing the course of the Crathis, so as to sweep it away. About 443 b.c., Thurii was founded near the site of Sybaris. After the destruction of Sybaris, Croton appears to have gradually declined, suffering much from internal convulsions (see **PYTHAGORAS**), as well as from the disasters which befall it in its wars with the Locrians, Rhegians (480 b.c.), and Bruttians, and also in those of Dionysius (q.v.) of Syracuse and Pyrrhus (q.v.). Its ruin was completed in the second Punic war; and although, in 194 b.c., it was colonized by Roman citizens, it never again rose to be a place of any importance. Croton, in the time of Herodotus, and at a later period, was famous as a medical school.

The modern town of Cotrone, standing very near the site of the ancient town, has a pop. of 6,878

SYCAMINE, a tree mentioned in Scripture, and supposed to be the black mulberry (q.v.).

SYCAMORE, or **SYCOMORE**, *Sycomorus*, a genus of trees of the natural order *moraceæ*, regarded by many botanists as a mere sub-genus of *ficus* (see FIG), and differing from the true figs only in the elongated, straight, thickened, and club-shaped stigma. The species are chiefly African, but the geographical range extends also into the w. of Asia. Some of them attain a large size and a great age. The **EGYPTIAN SYCAMORE** (*S. antiquorum* or *ficus sycamorus*), supposed to be the sycamore of the Bible, is a large tree, very abundant in Egypt and in some parts of the w. of Asia, often planted near villages for the sake of its shade, its wide-spreading head sometimes covering a space 40 yards in diameter. The figs are top-shaped, and grow in clustered racemes on the trunk and oldest branches. They are sweet, well flavored, and somewhat aromatic. The wood is light, porous, and of little value. It has been supposed that the cases of Egyptian mummies are made of it, but this is disputed. Other species are found in Abyssinia, south Africa, etc.

The sycamore tree of Britain is a species of maple (q.v.). In some parts of North America, the same name is given to the plane (q.v.) of that country, *platanus occidentalis*.

SYDENHAM, a chapelry in the parish of Lewisham, county of Kent, with a station on the London and Croydon railway, 8 m. s. of London. It has become of world-wide celebrity in connection with the Crystal palace, which was erected here in 1854, chiefly from the materials of the building of the great exhibition (1851). The cost of the erection and appointment of the Crystal palace amounted to nearly £1,500,000. The building is 1600 ft. long, 380 wide, and at the center transept 200 ft. high. The chief arts and sciences illustrated by the collections within the palace and grounds are sculpture, architecture, painting and photography, mechanics and manufactures, botany, ethnology, paleontology, geology, and hydraulics. There are two concert-rooms, within the larger of which, performances have taken place at which there were 5,000 vocalists and instrumentalists. The park and gardens occupy nearly 200 acres, and are adorned with sculptures, stone balustrades, etc., and fountains which are perhaps the finest in the world.

SYDENHAM, THOMAS, a great English physician, was born of good parentage, in 1624, at Winford Eagle, Dorsetshire, and was educated at Magdalen hall, Oxford. According to the well-known French surgeon, Desault, he afterward studied at Montpellier. He graduated at Oxford as bachelor in medicine in 1648. Through the interest of a near relative, he obtained a fellowship of All Souls college, and there continued to prosecute his medical studies. He left the university without taking a doctor's degree, which, indeed, he did not obtain till some time afterward at Cambridge. He settled as a practitioner at Westminster, and practiced so successfully that, when only 36 years of age, he already enjoyed the reputation of being one of the first physicians of the period. In his later years he was much afflicted by gout, which at length carried him off on Dec. 29, 1689. He was buried in St. James's church. Sydenham was not profoundly accomplished as a man of science; even in his own age, deficient as it was in the advanced development to which the researches on which medicine is based have now attained, he was inferior to several of his contemporaries; but in sagacity of observation and accuracy of diagnosis, he was unsurpassed. His skill and his philosophic cast of mind secured him the admiration and friendship of Locke; and his contributions to the literature of his profession received the praise of Haller and Beerhaave. His writings have been often republished both in England and on the continent, the edition entitled *Opera Medica*, which appeared at Geneva in 1716, being the best. Fevers were the department of medicine on which he first bestowed his attention; and before he had been many years in practice, he published, in 1666, his celebrated treatise entitled *Methodus Curandi Febres Propriis Observationibus Superstructa*. This was afterward reprinted in 1675, with the observations accumulated in the interval. His treatment of the then destructive malady of small-pox was especially felicitous, substituting, as he did, for the stimulating regimen in vogue, the antiphlogistic method of cool air and salines. The most scholarly translation of his works into English is that of Dr. R. G. Latham, published in the Sydenham society's series, to which he gives its name.

SYDNEY, the capital of New South Wales, and the oldest city in Australia, is situated on the southern shores of Port Jackson, in lat. 32° 52' s., long. 151° 11' e. The first party of British settlers that reached New Holland were landed at Botany Bay on Jan. 20, 1788. The spot which they here selected being found ineligible, it was abandoned a few days afterward, and the infant settlement was transferred to a point about 7 m. further to the n., to the place where Sydney now stands. The choice of the new locality was chiefly determined by the circumstance of a stream of fresh water being found there, flowing into the deep inlet known as Sydney Cove, one of the numberless bays into which the basin of Port Jackson is divided. This last-mentioned magnificent expanse of water, completely land-locked, and admitting vessels of the largest size, extends for some 20 m. inland, ramifying in every direction. Its bold and rocky shores present a succession of picturesque and beautiful landscapes. The cliffs which form the general outline of the harbor often rise to a height of from 200 to 250 ft. In other points, the coast presents a lower level, consisting of a series of terraces and smooth

sandy beaches. Perhaps there are few positions on the habitable globe more obviously suitable for the foundation of a great metropolis. Situated at a distance of about 8 m. from the sea, the whole circumference of the bay round which it is built forms a series of natural wharves, where vessels of 2,000 tons burden can be moored within a distance of 20 yards. The narrow entrance of Port Jackson—through what is called the "Heads"—might easily be made inaccessible to any hostile fleet; whilst the central position of Sydney makes it necessarily the permanent emporium of the greater number of the British dependencies in the southern hemisphere. The immense coal formation of east Australia extends n. and s. for some 500 m., with a breadth of from 80 to 100 miles. Sydney stands nearly in the center of this great carboniferous basin; and at various points within a radius of from 30 to 100 miles, large quantities of coal are raised for colonial consumption as well as for export. The sandstone rock upon which the city is erected affords a valuable material for building.

Since the abolition of transportation, the growth of Sydney has been rapid, the pop. in 1862 amounting to 93,596, and in 1871 to 134,758, including the suburbs. For many years Sydney enjoyed a monopoly of the commerce of these antipodean regions. It has now formidable rivals in Melbourne, Adelaide, and the settlements of Queensland. It must, however, continue the exclusive outlet for the productions and commerce of extensive pastoral and mineral districts on the n.w., w. and south-west. The eastern shore of Darling harbor has its frontage entirely occupied with wharves and quays.

The streets in the older parts of the town are narrow and irregular; in the newer portions, care has been taken to avoid these defects; and several of the modern streets, from their breadth and the size and style of the buildings, are not behind those of the principal towns of Europe. The shops, warehouses, and private buildings in George and Pitt streets present long and compact lines of well-built stone edifices, often assuming a very ornate and ambitious style of architecture. The chief thoroughfares are paved, and lighted with gas, and a system of underground drainage has been carried out at a cost of nearly half a million sterling. There is also an abundant supply of pure water, the source of which is a natural reservoir known as the Botany swamps. There are numerous parks near the city. The botanical gardens, the finest in the colonies, cover 38 acres. Sydney has one ship-building establishment. The Fitzroy dry-dock, originally intended for vessels of the royal navy, can take in vessels of the largest size. Lately, steps have been taken to put the city in a state of defense, and forts and batteries armed with powerful Armstrong guns have been erected. The *climate* of Sydney is, upon the whole, temperate and healthy.

Among public buildings, by far the most important edifice, not only in Sydney, but in the whole of the Australian settlements, is the university, which stands on a commanding height, and in the center of a domain of about 150 acres. The principal facade is 500 ft. in length, and is flanked at its western end by the great hall, the proportions of which are such that, were it in England, it would rank as the third in point of size. Lectures are delivered daily during each term on classics, logic, history, chemistry, natural and experimental philosophy, and jurisprudence. The museum contains a collection of Greek, Roman, and Egyptian antiquities presented by the former chancellor, sir C. Nicholson. There are two suffragan colleges in connection with the university—that of St. Paul's, belonging to the church of England; and St. John's, erected under the auspices of the Roman Catholic community. The university, erected out of public funds, has a permanent endowment of £5,000 a year from the civil list; and each of the suffragan colleges receives aid toward its building fund, and the stipend of the warden and rector. Eighteen free scholarships, of the annual value of £50 each, are established in the university, in addition to several others that have been founded by private benefactors. The university is incorporated under an act of the colonial legislature and by royal charter. It is only empowered, however, to confer degrees in arts, law, and medicine; and, so far as the university is concerned, instruction is limited to purely secular teaching. The religious training of the pupils is left to the affiliated colleges. The metropolitan cathedral of St. Andrew is a handsome building in the later perpendicular style of architecture. Many of the churches, upward of 120 in number, belonging to different religious denominations, are tastefully designed. Among the buildings devoted to secular purposes, the most imposing and effective, in point of size and architectural design, are the residence of the governor, the museum, the exchange, the custom-house, the town-hall, the new post-office, and the public grammar-school. The neighborhood of Sydney, with every nook in the adjacent bays, is studded with elegant villas and snug cottages, surrounded by their park-like grounds, and gardens of orange-trees, bananas, and numberless semi-tropical plants unfamiliar to the English eye of the newly-arrived immigrant. There are numerous manufactories; one with 350 hands makes boots and shoes, and 32 make clothing, one steam joinery employs 250 hands. Sydney has three theaters, several mechanics' institutes, a large hospital for the sick, an orphan asylum, and other charitable and benevolent institutions, all liberally endowed and supported by public grants or private munificence. Public traffic is carried by about 600 omnibuses and hackney-carriages.

SYDNEY, a t. in e. Nova Scotia, co. seat of Cape-Breton co.; pop. about 3,000. It is 285 m. n.e. of Halifax, in the e. portion of the island of Cape Breton, and while it

was a colony was its capital. It has an excellent harbor and lighthouse. It contains extensive coal mines 3 m. from the village, and is connected by a railway with the Bridgeport mines, 15 m. distant. It is also connected by rail with Louisberg on the s. shore of the island. It contains 6 churches, a court-house, 3 branch banks, a masonic hall, 2 newspaper offices, and several hotels. The trade with Newfoundland is considerable; it has a regular line of steamers to Halifax, and there is constant communication between this port and the islands of St. Pierre and Miquelon. Cattle, coal, and dairy products are exported. Besides ship-building, its manufactures are leather, iron, boots, and shoes.

SYDNEY, ALGERNON. See **SIDNEY** (*ante*).

SYENE. See **ASSOUAN**.

SYENITE, a granitic rock found near the city of Syene, in Egypt. It is composed of quartz, feldspar, and hornblende, and differs from true granite in having the mica replaced by hornblende. The feldspar is generally red (sometimes it is found of a white color), and the hornblende gives a mottled red and dark green color to the rock.

SYKES, GEORGE, b. Del., 1822; graduated at West Point, 1842; commissioned in the infantry and served in the Seminole and Mexican wars, behaving with great gallantry at Cerro Gordo. He was afterward employed on the frontier, and in 1851 was in Texas with rank of captain. He was present at Bull Run, and in the Virginia campaign in command of regular troops, and also at Antietam, Fredericksburg, Chancellorsville, and Gettysburg; and was brevetted maj. general. In 1866 he was mustered out of the volunteer service, and is now a col. in the regular army.

SYKES, OLIVE (LOGAN), b. New York, 1841; at the age of 13 made her debut on the stage in Philadelphia; wife of Edmund A. Delille, 1857-65, went to Europe in 1857; was educated in England, and contributed to English and French papers. In 1864 she appeared at Wallack's theater, New York, in *Heleen*, a play of her own composition; retired from the stage in 1868, and appeared on the platform as a lecturer on woman's rights, pursuing her former calling of newspaper correspondent and magazine writer. In 1876 she became the wife of Wirt Sykes, U.S. consul at Cardiff, Wales. She has published essays and lectures.

SYLLABUB, a culinary preparation, formerly much more used than at present. It consists of sugar and cream flavored with brandy, sherry, and lemon rind and juice, worked into a froth, and served up in that state in glasses.

SYLLABUS, a document published by pope Pius IX., 1864, condemning as heresies 80 doctrines which it calls "the principal errors of our times," dividing them into 10 sections; the 1st includes pantheism, naturalism, and absolute rationalism; the 2d, moderate rationalism; the 3d, indifferentism and latitudinarianism; the 4th, socialism, communism, secret societies, Bible societies, and other "pests of this description;" the 5th, errors concerning the church and her rights; the 6th, errors concerning civil society; the 7th, errors concerning natural and Christian ethics; the 8th, errors concerning Christian marriage; the 9th, errors concerning the temporal power of the pope; the 10th, errors of modern liberalism. Among the things thus denounced as errors are the principles of civil and religious liberty, and the separation of church and state. The document virtually declares that the pope is infallible; that Romanism has the exclusive right of being recognized by civil governments; that all other forms of religion are unlawful; that the papal hierarchy is independent of all civil authority, and that the Roman church has supreme control over education, literature, and science; with the right to enforce submission to its decrees. It reiterates all the papal claims of the middle ages, and declares war against modern social and national progress everywhere.

SYLLOGISM, a name expressing a principal branch or department of logic. When we reason, or get at truth by means of inference, we are said to proceed either inductively (see **INDUCTION**) or deductively. Deductive reasoning, when fully and methodically expressed, takes the form called the syllogism. "This thing will sink in water, for it is a stone," is a deductive argument, but not fully stated; the complete form is: "Stones sink in water; this is a stone; therefore, this will sink in water"—which form is called a syllogism.

To a perfect syllogism it is necessary that there should be three, and no more than three, *propositions* (see **PROPOSITION**); these are the conclusion, or the matter to be proved, and two others that are the means of proving it, called the premises. It is also necessary that there should be three, and no more than three, *terms*, namely, the subject and the predicate of the conclusion, and one, called the middle term, which must occur in both premises, being the connecting link for bringing the two other terms together in the conclusion. The *predicate* of the conclusion is called the major term, because it is in its scope the largest of the three; the *subject* of the conclusion is the minor term, as being the smallest in scope. The three terms enter into the premises in this manner: the major term and middle term make one premise, called the major premise; the middle term and the minor term make the minor premise. In the syllogism above stated, the terms are, "a thing that will sink in water" (major), "this thing" (minor), "stone" (middle); the premises are, "stones sink in water" (major), "this thing is a stone" (minor); the conclusion is, "this thing will sink in water."

The form now given, although the regular and fundamental form to prove any affirmative conclusion, is not the only form that an argument may assume. The totality of syllogistic forms is divided into *figures*, and each figure into *moods*, which are the distinct syllogistic forms, the principle of division being as follows: the figure is determined by the position of the middle term, which may be the *subject* of the major premise, and the *predicate* of the minor (1st figure), the *predicate* in both (2d figure), the *subject* in both (3d figure), the *predicate* of the major and the *subject* of the minor (4th figure).

The word "figure" is borrowed from rhetoric, where it means a departure from plain and ordinary speaking, as metaphor, hyperbole, etc. But, as remarked by Hamilton, only the last three of the foregoing enumeration should be called "figures." The first should be considered as embracing the regular forms of reasoning, and the others as properly figures—that is, forms more or less inverted, irregular, or unnatural, although still correctly representing reasonings that actually occur. These forms may be all *reduced* to forms in the 1st figure; their inversions or distortions being, as Hamilton would say, *redressed*, or restored to the primitive or fundamental type, namely, the syllogisms of the 1st figure.

The 4th figure did not belong to the original scheme of Aristotle, and it is usually considered as both unnatural and unnecessary, being only an awkward inversion of the first. There would then be the natural or standard syllogisms (the 1st fig.), and two sets of figurative departures from them (2d and 3d figs.).

The syllogisms of each figure are said to differ in *mood*, or according to the *quality* and the *quantity* of the propositions—that is, according as these are affirmative or negative (quality), universal or particular (quantity).

The entire scheme may be presented as follows: The symbols used are P (predicate of conclusion), major term; S (subject of conclusion), minor term; M, middle term. The general type of the first figure or standard is:

M is P.
S is M.
S is P.

When the quality and the quantity of the propositions are expressed, there arise four syllogisms of this form—two affirmative, and two negative:

All M are P.
All (or some) S are M. } *Barbara, Darii.*
All (or some) S are P. }

All matter gravitates.
All (or some) air is matter.
All (or some) air gravitates

No M is P.
All (or some) S is M. } *Celarent*
No S is P; some S is not P. } *and*
 } *Ferio.*

No matter is destructible.
All (or some) air is matter.
No air is destructible; some air is not destructible.

The general scheme of the 2d figure is:

P is M.
S is M.
S is P.

There are four syllogisms in all, which we may take in pairs thus:

No P is M.
All (or some) S are M. } *Cesare*
No S is P; some S are not P. } *and*
 } *Festino.*

"No destructible thing is matter," etc., as in the last form.

All P is M.
No S is M; some S is not M. } *Camestres*
No S is P; some S is not P. } *and*
 } *Baroko*

In this figure there is a certain distortion of the previous or regular figure. In the first of the two pairs, the major is, No P is M, instead of the equivalent (1st figure), No M is P. In the first form of the second pair, the minor is, No S is M, instead of the equivalent, No M is S, which should be the major to be regular; the amended premises would then give, in conclusion, No P is S, equal to No S is P.

All matter is extended. }
No mind is extended. } *Camestres.*
No mind is matter. }

The last form, with a particular conclusion, is exemplified thus:

All matter is extended.
Some things are not extended.
Some things are not matter.

This is a form technically called *Baroko*, which is one of two that are especially difficult to reduce to the standard forms.

This figure proves only negatives.

The scheme of premises in the 3d figure is

M. P.

M. S.

Six varieties of syllogism come under this figure; we may arrange them in three pairs, the first two pairs having the same major, and the third the same minor:

All M is P.
All (or some) M is S. } *Darapti*
Some S is P. } and
 Datisi.

All planets move.

All (or some) planets are heavenly bodies.

Some heavenly bodies move.

No M is P.
All (or some) M is S. } *Felapton*
Some S is not P. } and
 Ferison.

No solid body is perfectly transparent.

All solid bodies gravitate.

Some gravitating things are not perfectly transparent.

Some M is P; some M is not P. } *Disamis*
All M is S. } and
Some S is P; some S is not P. } *Bokardo*.

The first of the two is merely a standard syllogism (*Darii*), with transposed premises; the second (*Bokardo*) is more complicated, as in the example:

Some men are not fit to rule.

But all men are liable to have dominion.

Some men, liable to have dominion, are not fit to rule.

In the 4th figure,

P is M,
M is S,

there are five syllogisms. The mere forms are enough to quote:

All P are M.
All M are S. } *Bramantip*.
Some S are P. }

All P are M.
No M is S. } *Camenes*.
No S is P. }

Some P are M.
All M are S. } *Dimaris*.
Some S are P. }

No P is M.
All M are S. } *Fesapo*.
Some S are not P. }

No P is M.
Some M are S. } *Fresison*.
Some S are not P. }

The reasons why these syllogisms are true, and why no other of 256 possible combinations of propositions can give true conclusions, are certain laws, called the rules of the syllogism, which repose on first principles of the highest certainty.

Mr. Mill has laid down the following fundamental axioms of the syllogism, as stated in its standard forms in the first figure. (1.) "Attributes coinciding with the same attribute, coincide with one another." M, the middle term, coincides with P, the predicate; S, the subject, coincides with M; therefore S and P coincide with one another. (2.) "Any attribute incompatible with a second attribute, is incompatible with whatever that second attribute coincides with." No M is P; M is incompatible with P; but S coincides with M, and therefore it also is incompatible with P.

All the syllogisms of the last three figures are reducible to the first, by conversion of

propositions and transposition of premises, according to the nature of the case. The symbolic name of each syllogism contains instruction for this process, as well as stating the composition of the syllogism. To aid the memory, these symbols are put together in five Latin hexameter verses of very ancient but unknown origin:

"Barbara, Celarent, Darii, Ferioque prioris.
Cesare, Camestres, Festino, Baroko, secundæ.
Tertia Darapti, Disamis, Datisi, Felapton,
Bokardo, Ferison habet, quarta insuper addit
Bramantip, Camenes, Dimaris, Fesapo, Fresison."

The first line gives the standard figure, and states the propositions entering into each syllogism. The three A's in Barbara are three universal propositions. The E, A, E, in Celarent, are a universal negative, a universal affirmative, a universal negative; in Darii, A, I, I, a universal affirmative and two particular affirmatives, etc. In the other figures the commencing letter (C, B, etc.) shows which standard syllogism each is to be reduced to (Baroko to Barbara, Cesare to Celarent, etc.). The consonant *s* means simple conversion of the proposition marked by the preceding vowel; *p* means conversion by limitation, or *per accidens*; *m* signifies the transposition of the premises; *k* occurs in Baroko and Bokardo, and denotes that these are to be reduced by supposing the conclusion false, and then showing that on that supposition Barbara would be contradicted—from which it is inferred that the original form is true.

There are some species of deductive arguments that do not fall under the syllogistic figures. Thus, the major may state a conditional proposition, and the minor affirm the truth of the condition. "If the witness is to be believed, the man is guilty" (major): now "the witness is to be believed" (minor): therefore "the man is guilty." A true conclusion would also be obtained by a minor denying the consequent, "the man is not guilty." It would then follow that the witness (who affirms his guilt) is not to be believed. But no conclusion would follow from either denying the condition, "the witness is not to be believed," or affirming the consequent, "the man is guilty;" for, in the first place, the man might be guilty whether this particular witness be credible or not; and secondly, the guilt of the man does not prove the credibility of the witness. This is called the *conditional syllogism*.

Again, the major may be what is called a disjunctive or alternative proposition, from which also inferences may be drawn by supplying certain minors. "This was done by either A or B;" now "it was not done by A (or by B);" therefore "it was done by B (or by A)." Should the major be understood to mean that it was done by one, and not by both, there would be two other possible inferences. "It was done by A (or by B);" therefore "it was not done by B (or by A)." There are other disjunctive pairs, as for example: "Either A is B, or C is D;" now "A is not B, therefore C is D," etc. This is called the *disjunctive syllogism*.

A combination of the conditional and the disjunctive makes the *dilemma*. For example:

If A exist, then either B or C exists.
Neither B nor C exists.
Therefore A does not exist.

The following dilemma was given to refute the practice of torturing witnesses: "A person able to endure pain will be likely to utter falsehood under torture; one unable will be equally likely; therefore, a person under torture will be likely to utter falsehood."

A very great enlargement has been given to the doctrine of the syllogism by sir W. Hamilton (see *QUANTIFICATION*), prof. De Morgan, and the late prof. Boole of Cork. They have shown that many more syllogistic pairs can be created, and have invented symbols for the purpose. It is, however, comparatively few, either of the old pairs or of the new, that are assumed by the ordinarily occurring arguments, either in the sciences or in common affairs. By far the most useful part of the syllogism is contained within the limits of the first or standard figure, which shows what premises are to be looked out for to prove any conclusion; namely, some *general assertion* of matter of fact, affirmative or negative (major), and a *particular assertion* that a given thing comes under the subject of the general assertion (minor), and therefore falls likewise under its predicate. When an argument is stated in a puzzling or perplexed form, with perhaps the omission of one of its essential propositions, it is well to know how to supply the suppressed premises, and put the argument into regular order: the truth or fallacy of the reasoning then becomes evident at a glance.

SYLPHS, in the fantastic system of the Paracelsists, are the elemental spirits of the air, who, like the other elemental spirits (q.v.), hold an intermediate place between immaterial and material beings. They eat, drink, speak, move about, beget children, and are subject to infirmities like men; but, on the other hand, they resemble spirits in being more nimble and swift in their motions, while their bodies are more diaphanous than those of the human race. They also surpass the latter in their knowledge, both of the present and the future, but have no soul; and when they die, nothing is left. In form they are ruder, taller, and stronger than men; but stand nearest to them of all the elemental spirits, in consequence of which they occasionally hold intercourse with human creatures, being especially fond of children, and of simple harmless people; they even

marry with our race, like the undines and the gnomes, and the children of such a union have souls, and belong to the human race.

In common usage, the term sylph has a feminine signification, and is applied to a graceful maiden. How this curious change of meaning occurred is not quite certain; but it is probably owing to the popularity of Pope's *Rape of the Lock*, which introduced the term into the world of fashion and literature. For although even in Pope, the sylph that guards Belinda is a *he*, yet the poet so refined and etherealized his spiritual agents, that they soon came to be associated with all our ideas of feminine grace and beauty, and this circumstance may have reacted on the popular idea—always loose and inaccurate—of their character and sex, and brought about the change of gender to which we have alluded. See Paracelsus's *Liber de Nymphis, Sylphis, Pygmæis et Salamandris et Cæteris Spiritibus* (Basel ed. of Paracelsus's works, 1590).

SYLVESTER, the name of two popes, and of a third who was an anti-pope. The pontificate of the first immediately succeeded that of Melchisedes in 314, and is memorable for the great council of Nicæa, in which the heresy of Arius was condemned. Sylvester himself did not attend the council, but sent two priests—Vitus and Vicentius—to take his place. His name is also celebrated in connection with the so-called donation of Constantine to the Roman church, the spuriousness of which (although no doubt had been raised regarding it during many centuries) has long been admitted by critics. He died in 335. Sylvester II., one of the most learned of the mediæval popes, originally called Gerbert, was b. at Aurillac, in Auvergne, early in the 10th century. He was educated in the monastery of his native village; but went early to Spain, where he learned mathematics, and afterward to Rome. He was appointed abbot of the monastery of Bobbio, where he taught with much distinction and success. At a later period he went to Germany as preceptor of the young prince Otho, afterward Otho II.; and ultimately became secretary to the archbishop of Rheims, and director of the cathedral school, which became eminent under his care. The archbishop having been deposed, Sylvester was elected to the archbishopric; but he was afterward set aside, the deposition of his predecessor having been declared invalid. In the year 998, however, he was appointed archbishop of Ravenna, whence he was called to the pontifical throne, in the following year, under the name of Sylvester II. He was a man of rare acquirements for his age. He was an adept in mathematics, and in practical mechanics and astronomy, in which department his attainments acquired for him among his contemporaries the evil reputation of a magician. He is also believed to have been acquainted with Greek, and perhaps with Arabic. Of all his works, which were numerous, his letters (printed by Du Chesne in the *Historians of France*) have attracted most notice from their bearing on the history of an obscure period.

SYLVESTER, JAMES JOSEPH, b. London, 1814; educated at Cambridge university. He became a distinguished mathematician, and has been professor at the university of Virginia, University college, London, the Woolwich academy, and the Johns Hopkins university, Baltimore, Md., with which he is now connected. He has written several treatises on mathematical subjects, is the inventor of the "modified pantograph," and has made most important investigations in modern algebra.

SYLVESTER, JONATHAN, b. England, 1563. His life was divided between the somewhat incongruous pursuits of merchandise and poetry, in neither of which did he achieve a distinct success. Of his original works, the human memory retains no trace; but in virtue of the great, though fleeting popularity obtained by his English version of the *Divine Weeks and Works of Du Bartas*, from which Milton is thought to have derived some hints, he lives in literary history as a sort of *nominis umbra*. He led a somewhat wandering life, and died at Middleburg, in Holland, in the year 1618.

SYLVIADÆ, a family of birds, of the order *insectores*, and tribe *dentirostres*, including a very great number of small species, among which are many of the birds most noted for sweetness of song, while some of this power is possessed by almost all the family, so that the name *warblers* is often used as synonymous with *sylviadæ*. The bill is sharp, slender, straight, and rather compressed toward the tip; the wings moderately long; the legs slender. To this family belong the nightingale, the blackcap, numerous species known by the name of warbler, the redbreast, redstart, wheatear, whitethroat, stonechat, whinchat, golden-crested wren, hedge-sparrow, etc. The sylviadæ are diffused over all parts of the globe; and some of those found in tropical countries possess considerable musical powers, but are generally as silent during the great heat of the day as during the darkness of night, and are chiefly to be heard early in the morning.

SYMBOLIC BOOKS, in the language of the church, is a phrase that signifies the same as creeds and confessions (q.v.). The name is derived from the Greek *symbolon*, a sign or mark by which anything is known—a creed being the distinctive mark or watchword of a religious community.

SYME, JAMES, was born in 1799, in the county of Fife, and received a thorough education in art and medicine, in the university of Edinburgh. In his 19th year he began his anatomical studies under Liston, who appointed him his demonstrator. From 1825 to 1832, he lectured on surgery in the Edinburgh school, and, while generously refusing to lecture in opposition to his old master in the Edinburgh infirmary, he established a hos-

pital at his own expense, where he delivered a clinical course for four years. In 1831, appeared his well-known treatise on *The Excision of Diseased Joints*; and in 1832, his *Principles of Surgery*, which has since gone through many editions, and which has established his reputation as a teacher of the first rank. In 1833, he was elected to the chair of surgery in the university of Edinburgh, which he filled with the highest distinction. In 1847, he gave up his Edinburgh chair to fill that vacated in London by the death of Liston; but collegiate misunderstandings induced him, after six months, to return to Edinburgh. As an operator, Mr. Syme had no superior; as a teacher, he had no equal. His innovations in the practice of his art were characterized by so much ingenuity, controlled by scientific caution, that they were adopted by all really great surgeons. The best of his pupils, who are numerous, and scattered over every quarter of the globe, have been heard to declare that their soundest ideas in surgery are derived from Syme. Beside the works already named, he was the author of valuable treatises on diseases of the rectum; on the pathology and practice of surgery; on the urethra and *fixtula in perineo*; on incised wounds, etc. He died June 26, 1870. See the *Memoir* by Dr. Paterson (1874).

SYMMACHIUS, CÆLIUS, Pope, about 440-514; b. Sardinia; entered the priesthood, rose through the steps of sacerdotal rank, and in 498 was chosen as the successor of Anastasius II. But Laurentius, the favorite candidate of Festus, Anastasius I. and the Eutychians, had a strong following. As arbitrator Theodore I. of Italy favored Symmachus; but in 499 Laurentius returning to Rome, accused the pope *de facto* of bribery, and a contest, marked by violence and bloodshed, ensued. The council of 502 acquitted the pope of the charges of bribery and Manicheism. Symmachus was canonized after his death.

SYMMACHUS, Q. AURELIUS, a distinguished Roman orator, scholar, and statesman who flourished toward the close of the 4th c., was educated in Gaul, and after holding several lesser offices, became prefect of Rome (384 A.D.). Seven years later he was raised to the consulship. The date of his death is unknown, but we know that he was alive in 404 A.D. The character of Symmachus is a very fine one. A sincere pagan in an age when classic paganism was almost extinct, he proved in his own person a pattern of its choicest virtues, and manfully, if in vain, strove to regain for it a place of honor in the state. Symmachus's extant writings consist of ten books of letters (*Epistolarum Libri X*) and the fragments of nine orations. The former were published after his death by his son, and contain not a little that is valuable in relation to the history of the period; but the style is in general a slavish imitation of Livy. The best editions of the epistles are those of Juretus (Par. 1604) and Scioptius (Mainz, 1608). The fragments of the orations were first discovered by cardinal Mai in a palimpsest of the Ambrosian library, and were first published at Milan in 1815; afterward, with some additions, at Rome in 1823, in *Scriptorum Veterum Nova Collectio*. See Morin's *Etude sur la Vie et les Ecrits de Symmaque, Préfet de Rome* (Par. 1847).

SYMME, JOHN CLEVES, 1742-1814, b. Long Island; founder of the Miami settlements; member of congress, 1785-86; judge of the supreme court of New Jersey; chief justice of the north-west territory, 1788. He married a daughter of gov. William Livingston. His daughter became the wife of president Harrison.

SYMME, JOHN CLEVES, 1780-1829, b. N. J.; in 1802 he became an ensign in the U. S. army, and served with credit in the war of 1812. After the close of the war he became a resident of Newport, Ky., and spent his time in studying, writing, and lecturing on scientific and geographical subjects. He acquired some notoriety by his extraordinary theory that there is an opening at each of the poles, leading into the center of the earth, which he thought was hollow, and capable of habitation. He wrote *Theory of Concentric Spheres* (1826).

SYMMETRY OF ORGANS. Throughout the animal kingdom, a symmetry of organs very generally prevails in the two sides of the body. This is the case in man and in all the *vertebrata*; more perfectly, however, in the external than in the internal organs, the two sides of the body presenting great diversities in the circulating, digestive, and other systems. Even the external organs, although similar on the two sides, are never perfectly so. On comparing the two hands, for example, the veins of the one will be seen to differ from those of the other. In *mollusca*, the symmetry of the two sides sometimes exists, and is sometimes entirely lost, the one side remaining undeveloped in the growth of the animal. In the *articulata*, the symmetry is in general as perfect as in the *vertebrata*, and in the internal structure even more so. In the *radiata*, the whole type is very different, and a very different kind of symmetry appears, not with reference to two sides, but to the rays into which the body divides.

In the vegetable kingdom, a symmetry is found, more or less perfect, but never completely so, between the two sides of leaves, fronds, etc. In flowers, a symmetry appears in the regular distribution of sepals, petals, stamens, etc., around the center of the flower; and even those flowers which least exhibit it when fully blown, as papilionaceous flowers, possess it in the early stages of the bud as perfectly as others.

SYMONDS, JOHN ADDINGTON, 1807-71, b. England; educated at the university of Edinburgh, where he took a medical degree. He was physician to the Bristol general

hospital, and lecturer at the Bristol medical school. He published *Sleep and Dreams* (1851); the *Principles of Beauty* (1857), and *Miscellanies* (1871).

SYMPATHETIC INK. See **INK.**

SYMPATHY (Gr. *sympatheia*, fellow-feeling) may be defined as the assumption by different individuals, or by different parts of the same individual, of the same or an analogous physiological or pathological state at the same time or in rapid succession. The late Dr. Todd (art. "sympathy" in the *Cyclopadia of Anatomy and Physiology*) divides all the examples of sympathy which are included in the above definition into three classes; first, sympathies between different individuals; secondly, those which affect the mind, and, through it, the body; and, thirdly, those which are strictly organic, and therefore physical.

As examples of the *first class* may be mentioned the readiness with which the act of yawning is induced in a company, if a single person begins to yawn; the facility with which hysterical convulsions are induced in a female hospital ward by a single case; the fascination of its prey by the serpent, apparently by the power of the eyes; the similar power exerted by so-called electro-biologists and mesmerists, and by which some men can control even the fiercest carnivora. Of these sympathies the only explanation that can be given is that suggested in the article on Animal Magnetism (q.v.). As examples of the *second class*, the following cases may be adduced: certain odors—as of strawberries, mutton, cats, and other most diverse objects—will induce fainting in some people; the smell of a savory dish will excite a flow of saliva in the mouth of a hungry person; and the excitement of the emotions of pity will produce a copious flow of tears. In these cases, an affection of the mind is a necessary link, but why that affection of the mind should produce its peculiar effect, is a question not easily answered; but it is plain that the portion of the nervous center which is affected in such cases, must have a direct influence upon the parts in which the sympathetic phenomena appear, through commissural (or connecting) fibers, or the continuity of its gray matter with that of the center from which its nerves immediately spring. Examples of the *third class* occur in the pain in the knee which arises from disease of the hip-joint; the pain in the right shoulder from disease of the liver; the pain over the brow on taking a draught of iced water into the stomach; the various spasmodic affections connected with intestinal irritation, or the irritation of teething; the vomiting that occurs on the passage of a biliary or renal calculus, etc. All these cases may be more or less satisfactorily explained by the known laws of the sensory and motor nerves. In some of these cases the explanation, however, cannot be regarded as altogether complete. For example, the pain over the brow from the ingestion of cold water or ice into the stomach, may be referred to irritation of the gastric branches of the pneumogastric nerves communicated in the medulla oblongata to the fifth nerve; but why the irritation should be confined to the frontal branch of the first (or ophthalmic) division of the fifth nerve, we are utterly unable to explain.

SYMPHONY, in music, a word used in two different senses: 1. The instrumental introduction and termination of a vocal composition, sometimes called *ritornello*; 2. A composition for a full orchestra, consisting of from three to six movements. It is for the orchestra what a sonata (q.v.) is for a single instrument; but generally of greater length, and its movements more fully and richly developed, the subjects introduced being worked out in broader masses. The most usual though not unvarying order of movements is a brilliant allegro, ushered in by a slow introduction, an adagio or andante, a minuet with its trio, a short sportive movement called a scherzo, and a lively finale. The symphony is one of the highest of musical compositions, and one in which excellence is rare. Haydn, Mozart, Beethoven, and Mendelssohn are among the few successful composers of symphony; and the nine symphonies of Beethoven are generally acknowledged to be the greatest works of their class. The overture (q.v.) is in form not unlike a symphony, but much shorter; but the terms symphony and overture were at one time used almost synonymously, and several of Haydn's early symphonies are called overtures. At the present day the overture in the composer's score of an Italian opera is called *sinfonia*.

SYMPHYTUM. See **COMFRET.**

SYMPTOMS (Gr. *sympiptein*, to concur), in medicine, are the morbid phenomena by which the physician becomes aware that derangements of some kind have taken place in the economy; but it requires a mental effort to convert these symptoms into signs of disease. A symptom thus converted into a sign of some special disease or disordered condition, tends to constitute the *diagnosis*, or recognition of the disease. "The interpretation of symptoms," as Dr. Aitken observes, "can only be successful after a close observation of the patient—often prolonged and repeated for more complete investigation—so as to connect the results arrived at with his previous history. The utmost logical acumen is required for the due interpretation of symptoms. The individual value of each ought to be duly weighed; one symptom must be compared with another, and each with all, while the liability to variation of a similar symptom in different cases of a like kind must not be forgotten. Thus only can the nature of a disease be clearly determined, its severity and dangers fully appreciated, its treatment indicated, and the probability of recovery foretold."—*The Science and Practice of Medicine*, 3d ed. vol. i. p. 9. Many

writers, following the example of Laennec, confine the term *symptom* to the phenomena depending on vital properties; while those phenomena of disease which are more directly physical, they call *signs*. We thus have what may be called *physical signs* and *vital symptoms*. The form, size, color, firmness or softness, heat and odor of a part of the body, the sounds which it yields on percussion or dis-cultation, etc., afford *physical signs*; while *vital symptoms* may be exemplified in pain, uneasiness, altered or impaired sensations, spasm, vomiting, the accelerated pulse and hot skin of fever, the state of the tongue and of the alvine and urinary excretions, etc. The term *semiology* (literally, *the theory of signs*) has been given by medical writers to the general study of this subject, which is admirably discussed in Williams's *Principles of Medicine*.

SYNAGOGUE (Gr. = *ecclesia*; Heb. *beth-hakkeneseth*, house of assembly), a Jewish place of worship. The origin of this institution is probably to be traced to the period of the Babylonian captivity, although tradition finds it in the patriarchal times. When, at the time of Ezra, and chiefly through Ezra's instrumentality, the ancient order of things was re-established in Judea, synagogues were established in all the towns for the benefit of those who could not take part oftener than three times a year, or not even as often as that, in the worship of the temple at Jerusalem, and a special ritual of lectures and prayers was instituted. From the time of the Maccabees, we find them even in all the villages; and Josephus, Philo, the New Testament, the Mishna, and the Talmud, constantly allude to them. Common prayer and religious instruction were the purpose for which the people there met. The Sabbaths and feast-days were the principal times on which the faithful assembled in them; and they contributed more than anything else to the steadfast adherence of the people to their religion and liberty as long as there was any possibility of keeping both intact. At the same time they gradually undermined the priestly and aristocratic element that gathered round the temple, its gorgeous worship and kingly revenues. Little is known of any special laws respecting the construction of these buildings, save that the faces of the worshippers should be directed toward Jerusalem (*mizrach* = eastward) (see MOSQUE); or that, in accordance with the verse in the Psalms, there should be a slight descent of a step or two on entering it, or that it should stand, if feasible, on a slightly elevated ground, or be somehow or other made visible far off. Erected out of the common funds or free gifts of the community, it had also to be supported by taxes and donations. All profane doings were strictly prohibited in it. No eating, drinking, reckoning, and the like, were allowed; and even as to dress and other things of general decorum, the reverence due to the place was enforced as rigidly as possible. It represented in miniature the form of the temple, itself an enlarged type of the tabernacle. At the extreme eastern end was the *Aron hakkodesh*, the holy ark, containing several copies of the Pentateuch, from which the periodical readings were chanted. In front of this was the stand of the public reader of the prayers, not far from which was suspended the everlasting lamp (*ner tamid*). On a raised platform in the middle of the synagogue, was the place of the reader or preacher. The women sat separated from the men by a low partition five or six ft. high. The affairs of the synagogue were administered by a board of "ancients" or "elders," at whose head stood a chief or principal (*Rosh hakkeneseth* = *archisynagogos*). This college managed the inner affairs of the synagogue, and had even the power of excommunication. The officiating minister, whose office it was to recite the prayers aloud, was called *sheliach tzibbur*—messenger of the community (*angelos ecclesias*, Rev.). His qualifications were, among others, to be active, to be father of a family, not to be rich or engaged in business, to possess a good voice, to be apt to teach, etc. The beadle, or *chazzan*, had the general charge of the sacred place, and its books and implements. He had to present the scroll to the reader, and assist on other occasions. During the week-days, he had to teach the children of the town or village. He too had to be initiated by a solemn imposition of hands. This name of *chazzan*, however, at a later period, came to designate the officiating minister, and it has retained that meaning until this day. Almoners or deacons, who collected or distributed the alms, possibly the same as the *ballanin* or "idle men," whose office in relation to the synagogue cannot be exactly determined now, but who had always to be ready for the purpose of making up the requisite number of ten worshippers, were further attached to the general body of officials. Respecting the prayers used, we have spoken under LITURGY (JEWISH). As to the time of daily worship, we may observe that the third, sixth, and ninth hours of the day were the times appointed for it, and the more special days were the Monday and Thursday, when the judges sat, and the villagers came to town; and the Saturday, on which the forms of some of the prayers were altered according to the occasion.

On the connection between the Jewish synagogue and the Christian church, and their respective rites and modes of worship we cannot here enlarge. Thus much, however, we may say, that it is obvious to the most superficial observation that the principal practices of the latter belong, with certain modifications, to the former; and it has been conjectured that even the melodies of certain hymns still sung in the Roman churches are to be traced to the temple and the synagogues. It is, moreover, well known that the early Christian churches were entirely organized after the pattern of the synagogues. As to the judicial power exercised by the officers of the synagogue, we refer to SANHEDRIM. They had, there can hardly be a doubt, a kind of authority with

regard to religious transgressions; but how far they were allowed to carry this authority, is not so easily determined. Modern synagogues differ but in some minor points—additional prayers and the like—from what we gather to have been the nature of those at the time of Christ, save that there are no more elders, but a simple board elected from the community, without any authority beyond that of, perhaps, a board of church wardens, and that the chazzan, as we said, has now the functions of the “sheliach.” See JEWS, TEMPLE, LITURGY (JEWISH) etc. The languages used in the early synagogues of Palestine and Alexandria, were Hebrew, Aramaic, and Greek respectively.

SYNAGOGUE, THE **GREAT** (*keneseth haggadolah*), an assembly or synod, supposed to have been founded and presided over by Ezra, consisting of 120 men, said to have been engaged in remodeling the national and religious institutions of the Jews after the return from Babylon. The palpable chronological discrepancies that occur in the early accounts about this synod, together with other doubtful points, have led modern scholars to deny its existence completely. But the fact of Josephus not mentioning it avails very little against the positive assertions of the Talmud, and what is still more important, of the Karaites, the professed adversaries of all tradition. True, Ezra, the contemporary of Artaxerxes, can never have taken his place in it together with Zerubbabel and Joshua, who left Babylon under Cyrus, or with Simeon the Just, who lived at the time of Alexander the Great. These, however, are but apparent anachronisms. The tradition never meant anything else than that the institution founded by Ezra, and which lasted up to the time of Alexander, comprised 120 men, of whom Simeon was one of the last. Anyhow, there is absolutely no reason to doubt that Ezra and Nehemiah did a certain amount of work which they could not have done without being assisted by eminent collaborators. It was to this body to which certain vital ameliorations in the administration of justice are ascribed. They developed public instruction, and fixed and enlarged the Mosaic laws by certain rules of interpretation. “Be circumspect in judgment; make many disciples; and erect a fence around the law;” are some of the principal sayings ascribed to them. Above all, it seems to have been the office of Ezra and his coadjutors—the men of the Great Synagogue—to collect, purify, and redact the sacred books as much as in them lay. Whether, however, they really introduced the vowel-points, which have been handed down to us by the Masoretes, instituted the Feast of Purim, sanctioned the Eighteen Benedictions (see LITURGY, JEWISH), etc., is more than doubtful. They certainly disappeared before the Sanhedrim (q.v.) were instituted, but it may be that their legislative functions were no longer needed at that advanced period.

SYNANTHERÆ. See COMPOSITÆ.

SYNCLINAL AXIS is the line of curve in the trough of a series of beds from which the strata rise on either side. The ridge-curve is called the anticlinal axis.

SYNCOPATION, in music. Notes which begin on the unaccented part of a measure, and end on the accented, are called syncopated or driving notes. Their effect is to invert the rhythm, and lay an emphasis on the usually unaccented part of the measure, e.g.:

SYNCOPE. See FAINTING.

SYNCRETISM (signifying acting together as Cretans), a term used: I. In ancient times, *politically*, to designate the Cretan custom of disregarding all internal dissensions whenever a controversy with a foreign country occurred. II. In the 16th c., *philosophically*, to denote the efforts made to reconcile opposing systems. III. In the 17th c., *theologically*, first by Perus in his *Irenicon*, and afterward to describe the views of Calixtus and his followers, who sought to heal the schism in the church by making the traditions of the first five centuries of equal authority with the Bible, and by adopting the Apostles' creed as the common basis of all Christian denominations and a sufficient definition of true Christianity. The plan was that all holding these tenets should come into peaceful relations.

SYNDIC (Gr. *syn*, with, and *dikê*, justice), a name which has at different times and in different countries been given to various municipal and other officers. In Geneva the chief magistrate was formerly called the syndic. The syndics of cities in France, under the old régime, were officers delegated by the municipality as agents or mandataries; the various trading companies in Paris and the university had also their syndics; and in the university of Cambridge the same name is applied to members of special committees of members of the senate, appointed by grace from time to time for specific duties. See UNIVERSITY.

SYNECDOCHE (Gr. literally an “understanding one thing with another”) is a term in rhetoric denoting that mode of expression by which a part is put for the whole, and *vice versa*; as e.g., a door for a house, a sword for any weapon of war.

SYNERGISM (Gr. *synergeo*, to work together with), the name given to a doctrine of theology which teaches that in the work of conversion, the will of man is not wholly

passive, but can co-operate, through consent, with the Divine Spirit. About 1557 the question was hotly discussed by the Protestant theologians Pfittinger, Flacius, and Strigel, and soon the whole theological world was wrangling over the point. The Wittenberg divines were in favor of, the Mansfeld divines against, synergism. Finally, the *Concordien formul*, in its third article, condemned it.

SYNE'SIUS, b. Cyrene, Africa, about 379, from a rich and noble family; was a philosopher, poet, and Christian bishop. He was a pupil of the renowned Hypatia of Alexandria, afterward studied at Athens, and, returning to Cyrene, lived in retirement. He was sent to Constantinople to solicit aid for the people suffering from famine, and, soon after his return to Cyrene, was converted from paganism by the influence of his Christian wife. In 410, though not baptized, and married, and holding certain doctrines not considered orthodox, he was made bishop of Ptolemais. After baptism and seven months' preparation he entered upon his duties. His works, mostly epistles, treatises and hymns, were collected by Petavius in Greek, with a Latin translation, and published in 1612 and 1840. The hymns have often been published, in several languages. He is supposed to have died about 430.

SYNGENESIA. See COMPOSITE.

SYNGNA'THIDÆ. See PIPE-FISH.

SYNOD (Gr. and Lat., an assembly) in general signifies a meeting, but it is almost exclusively applied to ecclesiastical assemblies for the purpose of deliberating on doctrinal or disciplinary subjects. In church law, several kinds of synods—called also councils (q.v.)—are enumerated: (1) ecumenical or general, of the entire church; (2) national—that is, of the church of an entire nation; (3) provincial—that is, of a province; (4) diocesan, or of a single diocese. Of these, the ecumenical council has been already described. Of the others, little explanation is needed beyond what is conveyed in the names themselves. By the law of the Roman Catholic church, the decrees of a national or provincial synod must be submitted to the pope, and unless confirmed by him, or at least suffered to pass for two years without condemnation, are not held to have force. The diocesan synod is convened by the bishop, and consists of the members of the chapter, the benefited clergy having the permanent care of souls, and the heads of the communities of regular clergy. Synods of the English church are only held by the authority of the crown. A Presbyterian synod consists of only the ministers and elders within the particular district, generally one elder for each congregation. It is subordinate, however, to the general assembly, when there is a general assembly.

SYNO'DIC, the epithet applied to the period which elapses between a planet's appearance at one of the nodes of its orbit, and its return to the same node. See NODES and MONTH.

SYNONYM. When any one of several words will serve to name or express the same thing, that thing is said to be *polyonymous*, or many-named, and the words are called *synonymous* (Gr. names together, or in company). In this wide sense, *man*, *soldier*, *general*, *Frenchman*, might be called synonyms, as they can all be applied to denote the same individual—e.g., Napoleon. See NOUN. But the term is commonly applied in a restricted sense to words having substantially the same meaning, with only slight shades of difference—as *observe* and *remark*. In a settled and matured language, no two words can have exactly the same meaning; in such a case, one of them would be superfluous, and would be silently dropped. Words that were originally identical in application, have become differentiated by usage, each being appropriated to a special variety of the general notion.

The English language abounds in pairs of synonyms like *sharp* and *acute*, of which the one is Anglo-Saxon, the other borrowed from the Latin. It would be difficult to find a case of more exact correspondence of sense than *acutus* in Latin, and *sharp* (Ger. *scharf*) in Teutonic; but *acute* in English has become confined to the metaphorical sense of sharpness of the intellect or of the senses, the only case of its retaining the primary, physical signification being in the technical phrase, an "acute angle." *Sharp*, again, is applied both in the physical sense and also in the metaphorical; but metaphorical *sharpness* is not exactly the same thing as *acuteness*. A "sharp" lad is one quick in apprehension and movement; an "acute" intellect is one having great power of penetration and discrimination; while in a lawyer of "sharp" practice, a reprehensible moral quality is implied.

SYNOVIAL MEMBRANES AND FLUID. In every joint in which a considerable range of motion is required, the osseous segments (or contiguous extremities of bones) are separated by a space, which is called the cavity of the joint. The end of each of the bones entering into the composition of the joint is incrustated by a layer of articular cartilage adapted to its form, and the entire cavity of the joint is lined by a delicate membrane, which is termed the *synovial membrane*, which secretes a peculiar viscid matter, termed *synovia*, or *synovial fluid*, for the purpose of lubricating the inner surface. In its microscopical characters, a synovial membrane so closely resembles a serous membrane, that we shall content ourselves with referring the reader to the article on the latter structures. There are, however, certain points of difference, which are fully described in the article "Serous and Synovial Membranes" in *The Cyclopædia of Anatomy and Physiology*. Like

a serous membrane, a synovial membrane is always a closed bag, like the pleuræ, for example, with an attached and a free surface, the latter being smooth and moist. A very simple form of synovial membrane—anatomically known as a *bursa*—is employed to facilitate the gliding of a tendon of a muscle or of the integument over a projection of bone. It consists of a bag connected by areolar tissue with the neighboring parts, and secreting a fluid in its interior. These bags are sometimes prolonged into *synovial sheaths*, which surround long tendons, such as those of the flexor and extensor muscles of the fingers and toes. In deep-seated whitlow (q.v.), when inflammation extends to one of the sheaths, and gives rise to the formation of adhesions, the motion of the inclosed tendon is destroyed, and a permanently stiff finger is the result.

The *synovial fluid*, or *synovia* derives its name from its resemblance to the white of an egg (Gr. *syn*, with, and *ōn*, an egg). It consists of water holding in solution mucin, albumen, extractive matters, fat, and inorganic salts. The analysis of Frerichs shows that the composition and quality of the synovia vary essentially according as an animal is at rest or leads a wandering life.

SYNTAX (Gr. *taxis*, arrangement, *syn*, together) is the part of grammar that teaches the putting together of words for the expressing of thoughts; in other words, it treats of the construction of sentences. The first step is the analysis of sentences—the study of their anatomy and physiology, as it were (see SENTENCE). This important part of the subject is too often altogether overlooked. A clear perception of the mutual relations of the several members of a sentence makes the usual rules of syntax appear self-evident truths, and in most cases superfluous. Most of these rules fall under the heads of (1) concord and government, and (2) order of words or collocation. For details we must refer to special works on the subject.

SYNTHESIS (Gr. *synthēsis*, making a whole out of parts) is a term employed in chemistry to designate the building up of a more or less complicated product from its elementary constituents. As the synthesis of inorganic compounds is usually very simple, we shall confine our remarks to organic compounds. To take a very common substance as an illustration, there is no difficulty in resolving sugar into its ultimate elements, or, in other words, in ascertaining its composition by analysis. If we heat a little sugar to redness in a glass tube, it leaves a black deposit, which is carbon, while a liquid, which is water, distils over; and, on electrolyzing this liquid, we resolve it into hydrogen and oxygen; so that we can thus show that sugar is composed of the ultimate elements, carbon, hydrogen, and oxygen. An analysis of this kind shows that sugar may be represented by the formula $C_{12}H_{22}O_{11}$, and that one atom, or any given weight of it, contains 72 atoms or parts by weight of carbon, 11 of hydrogen, and 88 of oxygen. This pulling to pieces of the sugar is an easy matter, and has been known to chemists for more than half a century; but the putting together of the pieces, or, in other words, the synthesis of sugar, is a very much more difficult task. We may bring together carbon, hydrogen, and oxygen in the due proportions, and, to use the words of prof. Wanklyn (in a lecture delivered at the Royal Institution, Feb. 12, 1864), "we may shake them all together, or heat them, or cool them, and yet we shall never get them to combine so as to form sugar. Alcohol consists of 24 parts of carbon, 6 parts of hydrogen, and 16 parts of oxygen; but no alcohol ever results from making such a mixture. Neither sugar nor alcohol can exist at the temperature to which it is requisite to raise our mixture of carbon, hydrogen, and oxygen, in order to get chemical action to set in. At ordinary temperatures, the organic elements will not enter into combination, while at high temperatures they combine, it is true, but yield comparatively very few compounds." There was a general belief that organic products, such as sugar, alcohol, urea, oxalic acid, taurine, leucine, etc., required for their production a mysterious so-called *vital force*, totally distinct from the ordinary forces acting on matter. The first blow to this now obsolete doctrine was struck by Wöhler in 1828, when he discovered that the organic base *urea* might be artificially obtained. See ORGANIC COMPOUNDS. Three years afterward Pelouze obtained *formic acid* from inorganic materials. In 1845 Kolbe, by a somewhat complicated process, effected the synthesis of *acetic acid*, and consequently, indirectly, of its derivatives, among which may be enumerated *acetone*, the product of the destructive distillation of acetates; *marsh gas*, obtained by distilling an acetate with a caustic alkali, and *ethylene*; and the electrolysis of acetic acid, which Kolbe accomplished a few years afterward, yielded methyl and oxide of methyl, which latter could be transformed into any other methylic compound. During the last twelve years new and simpler methods have been suggested by various chemists, among whom Berthelot must be especially mentioned, and enormous additions have been made to the list of so-called organic compounds which have been synthetically constructed. We shall give a description of the mode of producing alcohol synthetically, and shall then show that from it, as a starting-point, an immense number of other organic compounds can be synthetically produced. To obtain this product synthetically, several distinct steps are necessary. The first is the formation of a transparent colorless gas, acetylene, C_2H_2 , from carbon and hydrogen in the electric arc; by passing this gas through sub-chloride of copper, acetylide of copper is produced, which, in contact with nascent hydrogen, gives olefant gas, C_2H_4 ; agitated with sulphuric acid, olefant gas produces sulphovinic acid, $C_2H_4O_2SO_2HO$ (a discovery due to our own chemists, Faraday and Hennell, in

1820). On distilling this acid diluted with water, dilute alcohol comes over, which, on redistillation, in contact with quick-lime, yields pure *vinic* or *ordinary alcohol*, $C_4H_6O_2$. Having thus obtained ordinary alcohol from inorganic materials only, we may employ it to form by synthesis an immense number of other organic compounds. By means of what is known as "the process of Mendius," we can, as it were, step from one alcohol to the next above it. Thus, from vinic alcohol ($C_4H_6O_2$) we obtain *propylic* (or *tritylic*) alcohol ($C_6H_{10}O_2$); from this we obtain *butylic* (or *tetrylic*) alcohol ($C_8H_{14}O_2$); from this, *amyllic alcohol* $C_{10}H_{22}O_2$, and so on. From the propylic alcohol thus obtained we get, by oxidation, *propionic acid*, from which *lactic acid*, the acid of sour milk, may be obtained; similarly, butylic alcohol yields butyric acid; every alcohol, in short, yielding a corresponding fatty acid by oxidation. *Glycerine*, the base of the fats, may also be obtained by a somewhat circuitous process. By combining glycerine with propionic acid, and with the other fatty acids which may be synthetically formed, we obtain several oils and fats similar to those which occur as natural products. The case of *taurine*, $C_4H_7NS_2O_6$, is even more striking; it is a product of various glandular metamorphoses, but its chief source is the bile, where it exists in conjugation with cholic acid as tauro-cholic acid. This highly complex substance can readily be formed in the laboratory from sulphuric acid, alcohol, and ammonia, each of which is capable of being built up from its constituent elements.

Sugar has been obtained by Berthelot from glycerine, a substance which is obtainable by purely inorganic means; but as he effected the conversion of the glycerine into sugar by the action of putrefying animal tissue, we can hardly regard the sugar thus formed as being of purely inorganic origin, although the animal tissue only acted catalytically, or as a ferment, and did not contribute any actual material to its formation. There is, however, no doubt that an unexceptional means of producing this important alimentary substance will soon be devised, since bodies strictly allied to sugar have been already obtained.* Another artificial compound of great interest in an industrial point of view is *toluol*, C_7H_8 , which has recently been obtained from phenole, which can itself be produced synthetically from alcohol. "Starting," says Dr. Odling, "from these two bodies, we may procure all the so-called coal-tar colors, with the brilliancy and variety of which most of us are now familiar. The red base or rosaniline, $C_{18}H_{12}N_3$, the violet base or triethylosaniline, $C_{22}H_{12}N_3$, and the blue base or triphenylosaniline, $C_{18}H_{12}N_3$, being producible in this way from their constituent elements, furnish admirable illustrations of the constructive powers of modern organic chemistry."

We cannot conclude without adverting briefly to the possibility of economically replacing natural processes by artificial ones in the formation of organic compounds. On this subject, one of our most distinguished organic chemists, Dr. Frankland, observes that "at present, the possibility of doing this only attains to probability in the case of rare and exceptional products of animal and vegetable life. By no processes at present known could we produce sugar, glycerine, or alcohol from their elements at one hundred times their present cost, as obtained through the agency of vitality. But although our present prospects of rivaling vital processes in the economic production of staple organic compounds, such as those constituting the food of man, are exceedingly slight, yet it would be rash to pronounce their ultimate realization impossible. It must be remembered that this branch of chemistry is as yet in its merest infancy; that it has hitherto attracted the attention of but few minds; and further, that many analogous substitutes of artificial for natural processes have been achieved."

For further details on this subject, the reader is referred to Berthelot's *Chimie Organique fondée sur la Synthèse* (2 vols. Paris, 1860); to the same author's lectures on the *Leçons de Chimie professées en 1860 et 1862*; to various lectures by Wanklyn, Frankland, and others, delivered at the Royal Institution; and to Odling's lectures *On Animals Chemistry*, delivered at the college of physicians in the year 1865.

SYNTONIN, or MUSCLE FIBRINE (Gr. *synteinein*, to render tense), contains in 100 parts: carbon, 54.06; hydrogen, 7.28; nitrogen, 16.05; oxygen, 21.50; and sulphur, 1.11. It is the principal constituent and the essential basis of all the contractile tissues. It may be obtained from muscular fibrin in the form of a coherent, elastic, snow-white mass; but whether it exists in the living body in a solid form or in solution, is undecided. Many recent physiological writers hold the latter view, and maintain that the phenomenon of cadaveric rigidity (*rigor mortis*) is due to its spontaneously coagulating after death.

SYPHILIS, is according to Dr. Farr's system of nosological classification, to be regarded as belonging to the enthetic order of zymotic diseases (see *NOSOLOGY and ZYMOTIC DISEASES*). These diseases have the common property of being developed in the system after the introduction by inoculation or implantation of specific poisons. The poisons which produce diseases of this order may be introduced through any abraded cutaneous surface, or through mucous membranes, especially if any solution of continuity occurs. A morbid poison thus introduced into the system produces a specific effect both on the tissue at the place of insertion and on the blood, as soon as the poison

* Carius, a trustworthy chemist, announced some years ago that he had succeeded in forming phenose, a kind of sugar, and possessing all its chemical characteristics, from benzol.—*Ann. d. Chem. u. Pharm.* Dec. 1865.

begins to be become absorbed; or, in other words, it produces both a constitutional and a local change. The absorbed virus seems to undergo the following changes in the living and infected body—viz. (1) Increase, (2) Transformation, and (3) Separation or excretion. Taking our illustrations from the disease to which this article is specially devoted, the *increase* is shown by the fact, that the pus from a single syphilitic sore may by inoculation be made to spread the disease a thousand-fold. The *transformation* is indicated by the successive phenomena which supervene during the course of the disease. For example, syphilis is followed, as we shall presently show, by a series of secondary and tertiary phenomena, which follow a tolerably uniform course in different patients. The *separation* or *excretion* of the poison may be accomplished in several ways. While in some of the more intense poisons—such as those of certain serpents—the whole mass of the blood seems rapidly affected, in others, as syphilis, “a double process of the zymotic-like action seems to take place before the full effects which the poison is capable of producing are completed. The multiplication of the venereal poison, and its effects upon the system, seem to become developed during the existence of the hardening process which surrounds the infecting venereal sore. This is the first zymotic-like process, and is attended with a local papule, and perhaps an ulcer. From this local sore the system becomes contaminated, and in the blood a second process (of zymosis?) appears to be completed, by which the original poison becomes intensified, its pernicious influence more complete, and its specific, secondary, and tertiary effects are more fully developed.”—Aitken's *Science and Practice of Medicine*, 3d ed., vol. i. p. 666.

From this brief sketch of the nature of ethnetic diseases, we turn to the consideration of the special disorder known as *syphilis*—a word whose origin is unknown. The terrible ravages of this disease among our soldiers and sailors, to say nothing of the fearful misery which it occasions in private life, afford more than sufficient apology for our introducing into these pages some of the most important details regarding this repulsive form of disease.* It is almost unnecessary to observe that syphilis is a contagious disease usually propagated by impure sexual intercourse. The following is a brief history of the course of the disease, if its progress is not checked by proper remedial agents. At an uncertain period, varying from three to ten days, after exposure to the infection, one or more venereal ulcers (commonly known as *chancres*) appear upon the generative organs. These ulcers present many varieties, which have been variously classified. The following arrangement, by Mr. Henry Lee, surgeon to the Lock hospital, is an eminently practical one—viz. (1) The Hunterian or indurated or infecting chancre; (2) The non-indurated or suppurative chancre; (3) The ulcerative chancre; and (4) The sloughing chancre. These local affections are so different in their characters, and in their action on the constitution, that each must have a brief separate notice. (1) The *indurated*, or, as it is frequently termed, the *Hunterian chancre*, from its having been first accurately described by John Hunter, is the only one of these local affections that can be associated with constitutional syphilis. Its natural course is thus described by Mr. Lee. “At an uncertain period, but generally from three to four days after exposure to infection, attention may be drawn to the part by a slight itching. On examination, a red spot, surrounded by a little induration, will, perhaps present itself, or a vesicle about the size of a millet-seed will not unfrequently form upon the infected part. The cuticle covering this vesicle is so thin that it usually gives way at a very early period; and this commonly happens before the disease has been carefully examined. The base of the vesicle then becomes indurated, and the induration (whether preceded or accompanied by a pimple or a vesicle, or independent of either of these) assumes a circular form, extending equally in every direction, and terminating quite abruptly in apparently healthy parts. A sore generally follows; this is excavated, without granulations, sometimes glazed, at other times having some adhesive matter on its surface. The color of the chancre will depend often upon the amount and character of the substance which adheres to it, and will frequently present a fawn hue, or different shades of brown and red. When this adventitious matter is removed, the sore will usually again assume its original smooth and red glazed appearance.”—“Syphilis” in Holmes's *System of Surgery*, vol. i. p. 400. This variety of sore frequently gives rise to a chronic enlargement of one of the glands of the groin (forming what is termed a *bubo*), which does not involve the skin or the cellular membrane. It is followed by certain

* Dr. Aitken observes that “no statistical nosology gives any idea of the number of men lost to the public service from syphilis. The loss of strength from venereal diseases alone (gonorrhoea being included with syphilis in this term, and forming about 40 per cent of the cases) is equal to the loss of more than eight days annually of every soldier in the service.” Dr. Balfour in his *Medical, Sanitary, and Statistical Report of the Army Medical Department for 1860*, relates that “more than one-third of all the admissions into hospital have been on account of venereal diseases (369 per 1000), and the average number constantly in hospital is equal to 23.69 per 1000 of strength (2,315 men), each remaining in hospital on an average 23½ days. Thus the inefficiency is constantly equal to about 2½ regiments.” In 1861, these diseases caused a loss equal to 8.69 days for every soldier serving at home, there being a daily inefficiency of 2,077 men; and the numbers are nearly the same for the succeeding years. The daily loss of service in the navy, in 1862, was about that of 586 men per day. How far these data apply to our civil population, it is hard to say; but it is much to be feared they apply pretty closely. “It is a question,” says Dr. Parkes, “whether a large majority of the young men of the upper and middle class do not suffer in youth from some form of venereal disease. In the lower classes, it is perhaps equally common.”—*Practical Hygiene*, p. 453. For a comparison between the amount of venereal disease in our own and other armies, the reader may consult the same work, pp. 502, 503.

constitutional symptoms known as *secondary symptoms*, and requires, both in its primary and secondary forms, mercurial treatment. (2) The *suppurating chancre* usually begins as an abrasion, which when fully developed, often presents the same appearance as if a piece of skin had been removed by a circular punch. The sore is covered with ill formed granulations, and extending equally in all directions, maintains its circular form. After continuing three or four weeks, it generally heals, without leaving the hardness which is so characteristic of the Hunterian, infecting or indurated sore. An other important diagnostic difference is furnished by the microscopico-chemical examination of the fluid secreted by the sore. In this suppurating sore the secretion consists of pus, which, on the addition of acetic acid, exhibits the characteristic compound nuclei; while in the infecting sore the secretion resembles turbid serum, presenting none of the characters of the pus. It does not give rise to bubo, nor is it followed by secondary symptoms. (3) The *ulcerative chancre* is a ragged worm-eaten ulceration; secreting an ill-formed pus, and presenting an irritable surface. Soon after the appearance of this sore, one of the glands of the groin will become enlarged and painful. This may be preceded by a shivering fit, more or less marked. The enlarged gland or bubo becomes very tender to pressure, and as the swelling increases, the skin becomes red, especially at the center, and the general symptoms of suppuration present themselves. Great relief is afforded by the discharge of the pus. It is never followed by secondary symptoms, and, like the preceding form, requires only local treatment. (4) The *sloughing chancre* is fortunately rare in this country, but in many foreign ports, in warm and hot countries, this form of syphilis commits great ravages among our sailors, who have given to it certain characteristic names, such as the *black pox*, the *black lion*, etc. It does not affect the inguinal glands, and is not followed by constitutional symptoms, and requires only local treatment.

Before noticing the constitutional or secondary symptoms which follow the Hunterian or infecting sore, we shall very briefly describe the treatment required for the last three forms, in which no constitutional symptoms occur. A suppurating sore should at once be thoroughly cauterized, so as to destroy all the tissues which have imbibed the poison. To secure this result, strong caustics are desirable; and as they sometimes extend further than is desired, an antidote should be at hand, which not only checks the further extension of the caustic, but deadens the pain. The agents most used in these cases are caustics and the mineral acids, and the *potassa cum calce*, a combination of potash and lime, which is prepared in the form of small rods for this purpose. The last of these is on the whole the best, as the extent to which it acts may be accurately regulated. When the action is sufficient, the application of a dilute acid will relieve the pain. Nitrate of silver, which is often employed, is not sufficiently energetic in its action to eradicate the disease. In the ulcerative sore, which is often irritable and painful, opium is useful both locally and internally. In other respects, the same treatment must be adopted as in the preceding variety. As the various means that have been suggested for preventing the suppuration of the bubo, which always accompanies this sore, are of no avail, it is useless to mention them. If, after the bubo has burst, the remains of an indolent, enlarged gland, incapable of forming healthy granulations, are left, caustic must be applied, so as to cause them to slough away. In sloughing sores, the great object is to check the destructive process; for which purpose, fomentations and poultices are applied locally, and large and repeated doses of opium are given internally. The nitric acid lotion, or a solution of potassio-tartrate of iron (10 grains to an ounce of water), is often an efficient local application in these cases.

We now return to the consideration of the Hunterian or indurated chancre, the only variety of venereal sore that gives rise to secondary or constitutional symptoms. If the patient seeks medical assistance as soon as he perceives the sore, it is possible that the application of a caustic will destroy the poison, and prevent any constitutional symptoms. If, however, four days or more elapse before treatment commences, the best local application is some form of mercury, as mercurial ointment spread on lint, or the application of black wash (see LORRONS) steeped in the same material. When the poison has once entered the circulation, and become diffused throughout the body, it is desirable to neutralize it, if possible, before the appearance of any secondary symptoms. A very large number of drugs have at different times possessed an anti-syphilitic reputation, and a few are doubtless useful; as, for example, iodide of potassium. "There is one medicine alone," says Mr. Henry Lee, one of the highest British authorities on the subject, "which, through good report and evil report, in spite of the strongest prejudices of some against its use, and the no less adverse influence of others, who have employed it to an unjustifiable extent, has maintained its general reputation."—*Op. cit.*, p. 418. In these remarks on the value of mercury (if judiciously given) we fully concur; but the mercurialists and non-mercurialists are almost equally divided. It may be given internally in pills or in solution; or it may be introduced into the system through the skin, in the form of ointment; or lastly, it may be employed in the form of vapor, and thus applied to the skin. Of these three methods, none is equal to mercurial fumigation by calomel vapor, either in the readiness with which it removes the symptoms, or the slight disturbance it excites in the constitution, or in its certainty in preventing relapse. This process is a very simple one. A piece of brick must be heated to a dull red heat, and placed in a pan having a little water at the bottom. A quantity of calo-

mel, varying from 10 to 20 grains, is placed on the top of the brick; and the patient then sits over the pan in a cane-bottomed chair, enveloped from his neck downward in a large blanket.* The operation is best performed at bedtime; it is complete in a quarter of an hour; and when the patient is sufficiently cool to put on his night-shirt, he should go to bed without disturbing the calomel on the surface of the skin. It is almost impossible to produce salivation by this means of administering mercury; and all that is requisite is to produce a slight tenderness of the gums. The system must be kept under this gentle influence of the mercury till the induration in the primary sore has disappeared. At a period usually varying from one to two months after the first appearance of the induration (which is regarded by some writers as the first of the secondary symptoms), slight febrile symptoms, usually followed by an exanthematous eruption of the skin, often accompanied by sore throat, will occur. This eruption is a variety of *roseola*; it is of a rose-red color, which disappears on pressure, and is not raised above the surface. It generally disappears in a few days, but if it persist, it will gradually change to a copper color, which is characteristic of all syphilitic eruptions which remain for a considerable time without suppurating or ulcerating. The syphilitic eruptions which usually follow this primary rash may assume the varied forms of lichen, syphilitic tubercle, lepra, and psoriasis; and the best mode of treating them is by applying local mercurial fumigation, and at the same time giving iodide of potassium (in five-grain doses thrice a day) internally. Occasionally, in persons with impaired constitutions, syphilitic eruptions assume a pustular character. For a description of these eruptions, we must refer to Cazenave's *Manual of Diseases of the Skin*, translated by Burgess. Similarly, there are cases in which, from some constitutional peculiarity, or, as Mr. Lee suggests, from some want of power in carrying out the natural processes of the disease, the syphilitic eruption may be accompanied by an effusion of serum only; or, in other words, may be of the vesicular type. Thus, we hear of syphilitic herpes, syphilitic eczema, etc. These forms must be treated as the others.

Among the secondary syphilitic diseases of the mucous membrane, may be especially noticed (1) mucous tubercles, (2) deep ulcer of the tonsils, and (3) syphilitic laryngitis. *Mucous tubercles* appear as small tense eminences inside the cheeks, on the arches of the palate, on the lips, on the generative organs, and on the rectum. A solution of corrosive sublimate applied locally (one or two grains to the ounce of water), or calomel, proves an effective local application. *Deep ulcer of the tonsils* is best treated by corrosive sublimate given internally, in doses of $\frac{1}{2}$ of a grain three times a day, in compound tincture of bark and water; and also used as gargle (in the proportion of 2 grains to a mixture of 7 ounces of water and 1 of honey). *Syphilitic ulceration of the larynx*, commonly known as *syphilitic laryngitis*, is characterized by pain or tenderness in the region of the thyroid cartilage (see LARYNX), huskiness of the voice, a hacking cough from attempts to expectorate, with occasional expulsion of purulent matter mixed with blood. If the disease is not checked, enervation, night-sweats, and dangerous exhaustion, ensue, and life is often terminated by suffocation.

In noticing the secondary symptoms, *syphilitic iritis* must not be overlooked; its symptoms and treatment are described in the article IRITIS.

Our limited space precludes more than a very brief allusion to the more important *tertiary syphilitic affections*. The most important of these are those which attack the bones and their coverings. They may be included under the heads of acute and chronic periostitis (the latter being very common), nodes and exostosis, inflammation of bone, caries, and necrosis; next to these are tertiary affections of the skin and mucous membrane, which consist mainly of intractable ulcerations attacking the face (especially the nose and lips), nails, ears, and mucous membranes of the various openings of the body; and diseases of the glands. In many of these cases a modified form of mercurial fumigation is most useful; but if mercury, even in this form, is thought inexpedient, in consequence of the general debility of the system, iodide of potassium, combined with any of the preparations of sarsaparilla, may be employed. Bark, iron, and the mineral acids are also of service in restoring the strength; and opium, by relieving the nocturnal pains which are so frequently present, will also prove most useful. The reader who wishes to pursue this subject further may be referred to Aitken's *Science and Practice of Medicine*, in which he will find an account of the tertiary syphilitic affections of the nails, heart, brain, lungs, liver, and tongue.

THE SYPHILIS OF CHILDREN is a subject which must not be omitted in an article on this disease. If the constitution of either the father or mother of an infant is saturated with the syphilitic poison, the child may be born with certain symptoms indicating that it is suffering from *congenital syphilis*. Moreover, the child of a mother having a primary sore, but no constitutional symptoms, may be inoculated with syphilis during the act of delivery; or the disease may be communicated in vaccination (if the matter be derived from an impure source); or by contact with syphilitic sores on the persons of wet-nurses or others. All these cases are included in the *infantile* variety of the disease. One of the most striking symptoms of true congenital syphilis is that which is popularly known

* A simple apparatus for mercurial fumigation, consisting of a kind of tin case containing a spirit-lamp, may be procured from Messrs. Savigny & Co., St. James's street, by those who object to rough bricks and coarse pans. A special fumigating cloak, in place of the blanket, is sold with the apparatus.

as the *snuffles*, in which a discharge collects in the nose, and sometimes blocks it up so completely that the infant is unable to suck for any length of time. The skin presents an eruption of spots, which are usually somewhat coppery, but sometimes of a rose-red tint; while on the soles of the feet and the palms of the hands the cuticle scales off, and an appearance like that of psoriasis is presented; and flat mucous tubercles occur at the parts where the skin and mucous membrane merge into one another. White ulcers of a crescentic form often occur in the mouth; and with these symptoms there is nearly always observed "the wizened and shrunken look, the anxious expression, and the dirty hue of the skin (a kind of dirty greenish yellow), which imparts to the infant a peculiarly repulsive aspect of old age."—Holmes, "On the Surgical Diseases of Childhood:" *op. cit.*, vol. iv, p. 830. Congenital syphilis frequently causes the death of the fetus at about the fourth or fifth month; and if a woman is repeatedly delivered of dead children from the fourth to the seventh month, the practitioner may fairly conclude that a syphilitic taint is *probably* present. In other cases the child is born alive with the "snuffling" and eruption; but, in the majority of cases, the infant when born is apparently healthy, and the disease does not show itself till about six weeks after birth.

When congenital syphilis is diagnosed with certainty the medical attendant has a very important duty to perform, from which he must not shrink from any feelings of delicacy. He must discover which of the parents is affected, and must prohibit further cohabitation until the secondary symptoms have been completely removed by the treatment which has already been described. "Neglect of this precaution," says Mr. Holmes, in his excellent memoir on congenital syphilis (contained in the 4th vol. of his *System of Surgery*), "may not only entail on the couple the misery of a family of deformed, puny, and ailing children, but to the woman at least is fraught with grave personal danger. Whatever may be the case among the poor, there is no doubt that, in the better classes, congenital syphilis is usually derived from the father, the mother being unaffected except through the fetus." There is scarcely a doubt that a woman carrying a syphilitic fetus may become thus infected with secondary syphilis by the exchange of fetal and maternal blood in the placenta; and this explains how it is that women who have never had the primary infecting sore occasionally show all the symptoms of secondary syphilis after living for some years with husbands similarly affected.

Allusion has already been made to the fact that *infantile* (not *congenital*) syphilis may be communicated by vaccination. There is undoubted evidence that in the year 1861, in a thinly populated district of Piedmont, in which syphilis is virtually unknown, 46 children of various ages were simultaneously attacked with syphilis proceeding from chancres in the arm, and followed by buboes (enlarged glands) in the armpits; and that all these children had been vaccinated directly or indirectly from a single child, who was subsequently proved to have contracted syphilis from a wet-nurse; and further, that these children transmitted the same disease to a number of women, their wet-nurses, mothers, etc., and even to children who nursed and played with them; that the women so infected communicated the disease to their husbands; and finally, that the disease yielded in all cases to the ordinary treatment adopted in syphilis. This, as Mr. Holmes observes, is by far the most convincing instance of the propagation of syphilis by vaccination; but several others are recorded by Mr. Lee (*Lectures on Syphilitic Inoculation*, 1863) and other writers.

Cases in which the nipple of the wet-nurse has been infected by a syphilitic infant are by no means rare, and have in various instances given rise to litigation.

Congenital syphilis and infantile syphilis generally must be treated with mercury—either in the form of inunction, by keeping a flannel band, smeared twice a day with mercurial ointment, in constant contact with the thigh or arm for about six weeks; or internally, by the careful use of gray powder (*hydrarg. c. cretâ*), in doses of a grain and half or two grains, twice a day; combined with a little compound chalk-powder, if any irritation of the bowels occurs. The snuffles will be relieved by syringing the nostrils with lukewarm water, and then introducing a couple of drops of almond or olive oil.

In a foot-note to an early paragraph of this article, we gave abundant evidence of the appalling prevalence of this disease. In his valuable treatise on *Practical Hygiene*, Dr. Parkes discusses the question of the prevention of this disease among soldiers; as, however, his remarks for the most part are applicable to other classes, we shall briefly notice them. The means of prevention which he discusses are. 1. *Continence*, which is promoted by (a) the cultivation of a religious feeling and of pure thought and conversation; (b) the removal from temptation and occasions to sin; (c) constant and agreeable employment, bodily and mentally; and (d) temperance. 2. *Early marriage*.—At present only 6 per cent of our soldiers are allowed to marry. 3. *Precautions after the risk of contagion*.—In some French towns the use of lotions and washing is vigorously enforced, with the effect of lessening disease considerably. 4. *Cure of the disease in those affected by it*.—Health-inspection, in special reference to venereal diseases, are made weekly in our army by the surgeon or assistant-surgeon; and although similar inspections of all recognized prostitutes have long been made by legal authority in many parts of the continent, no attempt at legal interference with the disease in women was made in this country till 1864, when the "contagious diseases bill" was passed, by which, in the neighborhood of certain places (Portsmouth, Plymouth, Woolwich, Chatham, Sheerness, and Aldershot), prostitutes who are found diseased may be taken to an hospital, and

there detained till cured. A committee appointed a few years ago by government to report upon the best means of checking the disease in the army and navy, in Feb. 1866 issued their recommendations; the most important of which are—(1) the periodic inspection of all known prostitutes in the garrison towns placed under the provisions of the act of 1864; (2) the appointment of a surgeon vested with the necessary powers; (3) punishment for infringement of the act; (4) the extension of its operation to all garrison and seaport towns used by troops or ships; (5) the prohibition of the residence of public women in beer-shops; (6) that the Lock hospitals be placed under government control, and lastly, that the police supervision of the women in the streets of such towns be more stringent. The evidence taken by this committee unquestionably proved that the working of the act of 1864 was decidedly useful, although its application was so limited. For an account of the various plans which are adopted on the continent for the prevention of this disease—such as the registration of brothels and of prostitutes, and the enforcement of periodic examinations at short intervals—the reader is referred to the various works of Parent-Duchatelet, Acton, Sanger, and others on prostitution; and to two articles on the same subject by Dr. Holland (of Cork) in the *British and Foreign Medico-Chirurgical Review* for 1852.

Without entering into any prolonged details regarding the history of this disease, we may briefly mention that, toward the close of the 15th c., a great epidemic of syphilis pervaded Europe, and that it was supposed to have been imported from the new world; and that, in the 16th c., syphilis was recognized as the result of a specific virus. During last century the history of this disease is divisible into three distinct periods, in each of which very different views have been prevalent. These may be described as—1. *The period and doctrine of Hunter*, who believed that the various forms of syphilis and gonorrhea depend upon one and the same poison—a view taught by Carmichael in Dublin, Cazenave in Paris, and others. 2. *The period and doctrine of Ricord*, who proved that gonorrhea was quite different from syphilis, and that inoculation with gonorrheal matter will not cause a chancre; and that there are *two* classes of chancers, the *soft* and *hard*, originating from the same source. 3. *The present period*, commencing in 1856, in which it is held that, exclusive of gonorrhea, there are *two* forms of the syphilitic poison. It has been judiciously advised by Mr. Longmore, the professor of military surgery in the army medical school, that in accordance with our present knowledge of this disease, the term *syphilis* or *syphilitic* should be restricted to such cases as are believed to be of a specific infecting kind, while the term *local venereal sore* or *venereal ulceration* should be applied to those cases which require merely local treatment, and are not followed by constitutional symptoms.

SYPHILIZATION is the term used to designate an operation which has the double object of eradicating syphilis already existing in the system, and of securing permanent immunity from any future attacks, by means of repeated inoculations of syphilitic poison. As long ago as the year 1844, a French physician, Auzias Turenne, undertook a number of experiments, with the view of testing whether John Hunter's view, that syphilis could not be communicated to the lower animals, was correct. After some failures he succeeding in producing venereal sores (chancers) in monkeys by inoculating them with the human virus; and he found that rabbits, cats, and horses might be similarly infected from the chancers of the monkey. He likewise found that the chancers produced by inoculation became less and less in each animal, until a period at length arrived at which the poison seemed to have lost all its power, and no further sores could be produced; and he was thus led to believe that by prolonged inoculation the system became protected. The subject was next taken up by Sperino of Turin, who inoculated patients suffering from syphilis by virus from a chancre, and repeated the inoculation once or twice a week, till the poison—as in the case of Turenne's animals—ceased to produce any effect; and when this point was reached, all the other sores had healed. In 1851 prof. Boeck of Christiania, when traveling through Italy, had his attention drawn to the doctrine of syphilization; and from that time to the present, he has devoted himself unremittingly to it, and is now the great authority on the subject. In 1858 Boeck, in consequence of the results he had attained from the practice of syphilization in cases where no mercurial treatment had been prescribed, alleged that syphilization might in such cases be regarded as a complete and certain cure. In cases where mercurialization has been practiced, the use of iodine has to be persisted in during syphilization. During the summer of 1865 Dr. Boeck visited London, and took active steps to make his views on this subject accurately known in this country, and the surgeons of the Lock hospital submitted a series of cases to his mode of treatment; and Mr. James Lane, one of the surgeons to that institution, asserted in 1866 that “hitherto, as far as he had seen, it had effected everything which had been promised for it. The progress of the cases in the Lock hospital had in almost every detail corresponded to the predictions of prof. Boeck respecting them. In several of those who had been longest under treatment, immunity from inoculation with primary syphilitic matter had been arrived at.” The progress of syphilization as a remedy for syphilis and as a proof against syphilitic infection, has not been well marked in this country. Most surgeons are agreed as to the correctness of prof. Boeck's views, but the practice itself is offensive, and the length of time necessary for its being effectively carried out forms

an objection to its practice. In Sperino's experiments, the treatment extended from 9 to 20 months or more. The practice has been much in vogue in Christinia under Boeck and his colleague M. Bidekap; but it is unlikely to command attention other than of scientific kind, and as tending to acquaint us with the history of syphilis and with the nature of syphilitic infection.

SYRA (anc. *Syros*), the most important, though not the largest member of that group of islands in the Ægean sea known as the Cyclades (see GREECE), lies 13 m. s. of Andros. It is about 10 m. long by 5 broad, bare, hilly, and not very fertile. The products are wine, tobacco, grain, citrons, figs, honey, and vegetables; but the greater portion even of the common necessities of life have to be imported from Greece and foreign countries. Its prosperity is of quite modern growth. During the war of independence, Syra remained neutral, and, in consequence, numerous fugitives flocked thither from other parts of Greece, especially from Chios and Psara, who, besides adding largely to the population, brought with them a spirit of political activity and commercial enterprise, the beneficial effects of which are now strikingly visible. Pop. 30,643. The capital, *Syra* or *Hermopolis*, is situated on a bay on the e. side of the island. It rises terrace-wise from the shore, is well built, and is the seat of government for the Cyclades, and the residence of foreign consuls. It has numerous educational institutions, 4 printing-presses, and 3 weekly newspapers. Syra has become the great commercial entrepot of the Ægean. Nearly one-half of all the imports of Greece reach it through this port. It builds more ships than any other town in the Levant, and owns one-third of all the Greek merchantmen. It has likewise regular steam communication with all the principle trading-towns in the Levant. Pop. of the town of Syra, '71, 20,996.

Ancient notices of Syra are scanty. Homer praises it in the *Odyssey* as "rich in pastures, in herds, in wine, in wheat;" but it has no history.

SYRACUSE, anciently the most famous and powerful city of Sicily, situated on the south-eastern coast of the island, 60 m. s.s.w. of Messina, was founded by a body of Corinthian settlers under Archias, one of the Bacchiadae, 734 B.C. The original colonists seem at first to have occupied nothing more than the little isle of Ortygia, about 1 m. long, and half a mile broad, which lies near the shore. It rapidly rose to prosperity, and was enabled to establish sub-colonies of its own: Acrae (664 B.C.), Casmenae (644 B.C.), and Camarina (599 B.C.). Nothing definite is known of the early political state of Syra; but before 486 the political power had passed into the hands of a few leading families, or perhaps *clans*, who constituted an oligarchy, while the great body of the citizens formed a malcontent democracy. In that year a revolution took place. The oligarchic families—*Geomori* or *Gamori*, "landowners;" probably the descendants of the original colonists, like the patrician *gentes* of Rome—were expelled, and the sovereign power was transferred to the citizens at large. Before a year passed, however, Gelon (q.v.), "despot" of Gela, had restored the exiles, and at the same time made himself master of Syracuse. He was a great ruler, and under him the city increased in size and wealth. It is believed to have been in Gelon's time that the adjoining mainland was first built upon. The locality of the new settlers was the slopes and heights of Achradina, or the "outer city," a triangular table-land n. of the island of Ortygia, and subsequently connected with it by a mole. It ultimately became the most extensive and populous quarter of Syracuse—contained the agora, a temple of Zeus Olympios, the Prytæum, with a splendid statue of Sappho, the fine monuments to Timoleon and the elder Dionysius (q.v.), etc. It may be convenient to mention here the other two quarters of the city, especially as the date of their settlement is not known. These were Tyche—so called, according to Cicero, from an ancient temple of "fortune" erected there—occupying a plateau to the w. of Achradina; and Neapolis (new city), stretching along the southern slopes of the plateau, and overlooking the marshes of the Anapus and the "great harbor," a spacious and well sheltered bay, about 5 m. in circumference. Neapolis became one of the finest parts of Syracuse. Here were situated the theater, amphitheater, and numerous temples, of which hardly a relic remains, except of the first mentioned. Ortygia contained the castle or citadel which immediately fronted the mainland, and overlooked the docks or *navalia* in the "lesser harbor."

Reverting to the history of Syracuse, which we must touch upon only in the most cursory manner, a noticeable characteristic of the reign of Hiero (q.v.), the successor of Gelon, is his cultivation of the fine arts, and his liberal patronage of men of genius, as Æschylus, Pindar, etc. In 466 B.C., the democracy again got the upper hand—Thasybulus, a "tyrant" of the baser sort, being expelled; and for sixty years a free and popular government was enjoyed, under which Syracuse flourished more than it had ever done. During this period occurred its great struggle with Athens (413-414 B.C.), in which it came off victorious, and its renown at once spread over the whole Greek world. But a new power appeared on the stage—the Carthaginian, whose conquests in Sicily, toward the close of the 5th c., threatened the supremacy of Syracuse. Meanwhile, Dionysius (q.v.) restored the "tyranny" of Gelon, and during a reign of 38 years greatly increased the strength and importance of the city. It was he who constructed the docks in the greater and lesser harbors, and surrounded the city with fortifications. His fierce and victorious war with Carthage (397 B.C.) raised the renown of Syracuse still higher. The reigns of the younger Dionysius (q.v.) and of Dion were unsettled; but

after the restoration of public liberty by Timoleon (344 u.c.), a brief season of tranquillity ensued, during which the prosperity of the city rapidly revived. Under Agathocles, however, the despotic form of government was again established (317 B.C.), and continued, with scarcely an interruption, down to the conquest of the city by the Romans (212 B.C.) during the Hannibalic war—the ruler of Syracuse, Hieronymus, a rash and vain young man, having abandoned the prudent policy of his grandfather, Hiero (q.v.), broken the alliance with Rome, and joined the Carthaginians.

Under the Romans, Syracuse slowly but surely declined, though it always continued to be the capital and first city of Sicily. Captured, pillaged, and burned by the Saracens (878 A.D.), it sunk into complete decay, and is at present confined to its original limits, Ortigia, which, however, is no longer an island, but a peninsula. Pop. '72, 22,179. The streets of the modern town are, with few exceptions, narrow and dirty. Syracuse has a cathedral, a museum of classical antiquities discovered in Syracuse and the neighborhood, a public library, with some curious MSS., numerous churches, monasteries, and nunneries, and carries on a trade chiefly with Malta in wine, oil, salt, and salt fish. It has several remains of ancient and medieval edifices, which are much visited by travelers.

SYRACUSE, a province in e. Sicily, on the coast; drained by the Abisso, Anapo, and Ragusa rivers; about 1400 sq.m.; pop. '72, 294,885. The surface is mountainous except in the south. Along the sea-coast and in the river valleys the soil is fertile, and adapted to pasturage. Agates and marbles are found. The principal agricultural productions are corn, barley, hemp, flax, wines, and olives. It comprises 3 districts, Syracuse, Modica, and Noto. Capital, Syracuse.

SYRACUSE, a city of central New York, at the head of Onondaga lake, on the Erie canal, and at the junction of the New York Central and Oswego railways, 148 m. w. by. n. of Albany. From its central position it is called the city of conventions. It contains a handsome court-house, state arsenal, state asylum for idiots, 41 churches, 3 daily and 11 weekly newspapers, 13 banks, schools, and libraries. Here are the largest salt-works in America (producing in 1874, 6,029,300 bushels of salt), 5 iron-furnaces, 14 machine-shops, manufactories of silver, tinware, sheet-iron, coach and wagon factories, and breweries. Pop. '75, 49,808.

SYRACUSE (*ante*), a city and county-seat of Onondaga co., N. Y.; pop. '80, 51,791. Its public buildings include the court-house, banks, and churches; it is well laid out, and the Syracuse university and Oakwood cemetery are objects of interest to visitors. Its principal industry is the manufacture of salt, which has existed from the first discovery of the springs by the Jesuits in 1654. In 1797 these were taken possession of by the state, and laws passed for the conduct of the manufacture. Twenty salt companies now pursue this industry, having invested in it a large capital, and employing many operatives. From 1797 to 1806, inclusive, the quantity manufactured was 78,000 bushels; 1807 to 1816, 267,000; 1827 to 1836, 1,594,000; 1837 to 1846, 3,058,000; 1847 to 1856, 5,083,000. The salt-springs are on the shore of the lake, near the city, and are reached by horse-cars. The entire product of all the manufactures of Syracuse was valued in 1874 at about \$14,000,000. The most important include Bessemer steel works, rolling-mills, blast furnace, foundries, and boiler-works, railroad journal-boxes, fruit-canning, musical instruments, etc.

SYRIA (Arab. *E'sham*, Turk. *Soristan*), a division of Asiatic Turkey, bounded on the n. by portions of Asia Minor, on the w. by the Levant, and on the s. by Arabia Petrea; on the e. and s.e. its boundary is rendered indefinite, in great part, by the sands of the desert, but at length becomes fixed by the course of the Euphrates. It is divided into several governments, which frequently change their limits. They are usually named after the principal towns—Aleppo, Damascus, and Beyrout. The area is about 146,000 sq.m.; pop. about 2,250,000. The whole region is traversed by a double mountain-chain—of which Lebanon (q.v) forms the highest part—touching in its northern extremities the Alma Dag (anc. *Mons Amanus*), and in its southern forming the Sinaitic range. The central part of this mountain system, which in many places exhibits the characteristics of a plateau, presents on the w. a steep front toward the Mediterranean, but on the e. rolls gradually away into the level uplands of the Syrian wilderness. The most noticeable features of the long *furrow* between the double ridge, beginning at its southern end, the gulf of Akaba, are the waterless wady of Arabah, the narrow, deep-sunken region known as *El Ghur*, through which the river Jordan flows, and which embraces the Dead sea and the sea of Galilee, and the vale of Cœle-Syria (q.v.), and its great continuation northward, watered by the Nahr-el-Asy (anc. *Orontes*). The western ridge is broken through in three places: in the n. by the lower Orontes; in the middle near Tripolis—where the chain of Lebanon properly terminates—and further s., near Tyre, by the Leontes. South of Tyre it recommences in the hill country of western Palestine (q.v.), which finally passes into the desert plateau of El Tyh, in the Sinaitic peninsula. The eastern ridge is less sharply defined, its most conspicuous elevations being Anti-Libanos, the mountains of Moab (east of the Dead sea), and Mount Seir, overlooking the wady Arabah. The principal rivers are the Orontes (q.v.), the Leontes, the Jordan (q.v.), the Barada or Abana, the river of Damascus. The only lakes worth mentioning are the Dead sea (q.v.) and the sea of Galilee.

Although Syria belongs to the countries comprised within the Asiatic rain-zone, yet in general the climate is excessively dry and hot, differing little from that of Arabia. Drought and scantiness of vegetation characterize almost equally the uplands and the valleys. Only where the mountains are lofty, the streams abundant, and the atmosphere somewhat maritime, as in the terraced slopes of Lebanon, do we find some approach to tropical luxuriance in flower, and fruit, and tree. Forests of evergreen, beautiful grassy pastures, and meadow-tracts are found there; and wheat, maize, rice, etc., are largely produced. The cultivation of the vine, the cotton tree, the mulberry, and also the finer sorts of fruits, as the olive and fig, is considerable, while indigo and sugarcane are raised in the valleys of the Jordan and the region round about the Dead sea. The fauna of Syria, like its climate and vegetation, is similar to that of Arabia. The camel is of almost as much importance as further s., and the Syrian deserts, particularly toward the n., are the home of gazelles, hyenas, jackals, bears, buffaloes, and other wild animals.

The greater part of the Syrian mountains is limestone; mountain limestone in Lebanon, chalk in Anti Lebanon, and Jura limestone in Palestine. In the last of these volcanic formations occur, especially in the region of the Jordan and the Dead sea, where hot springs, beds of bitumen and sulphur, the shapes of the hills, and the frequent earthquakes afford unmistakable evidence of volcanic activity. Salt is the only mineral of much consequence, and is exported in considerable quantities; coal, however, is worked near Beyroot. Sheep, goats with hanging ears and silky hair, cattle, mules, and asses form, as in ancient times, a great part of the wealth of the inhabitants.

Silk is the chief article of manufacture—at Aleppo, Beyroot, Damascus, etc.—but cotton and woolen fabrics, gold and silver thread-stuffs, glass, earthenware, leather, soap, etc., are also manufactured in different parts of the country. The want of roads is a great hindrance to industrial activity. The first carriage-road was opened in 1863, between Beyroot and Damascus. The other roads, with the exception of one or two short carriage-ways in mount Lebanon, are mere mule and camel tracks. In 1871 Syria exported grains, seeds, cotton, galls, wool, etc., to the value of £717,404; and imported cottons, woollens, copper, tin, iron, coals, indigo, pepper, coffee, etc., to the value of £1,338,750.

The *religious* sects of Syria are numerous. Most of the people are Mohammedans, but Christians of the Greek church number 180,000; Maronites (q.v.) and Roman Catholics, 310,000; Jews, 40,000; Druses (q.v.), 90,000; lesser sects, about 30,000. The inhabitants are in some sense a mixed people, for the country has experienced many political vicissitudes, but by far the greatest number, whether Christians or Mohammedans, are of Shemitic origin, either Phenician, Aramæan, or Arabic. Their Turkish rulers, however, and such Turkomans and Kurds as we find settled in the n. of Syria, belong to the Turanian race. Arabic is everywhere spoken, and may be considered the national language, since the old Syriac or Aramaic tongue is wholly dead, except among the Nestorians of Kurdistan.

The *history* of Syria stretches far back into remote antiquity. In the time of Abraham (2,000 B.C.) Damascus was a city; in the oldest literature of Greece Sidon figures as the capital of a rich, populous, and civilized state; and in the Hebrew Scriptures, Canaan or Palestine is crowded with towns at the period of its conquest by Joshua; but, like most other so-called nations in early times, Syria did not form a single state; it was rather a congeries of independent states whose inhabitants belonged to the same race. Every important city had its king, whose normal occupation was fighting with his neighbors. Under David and Solomon something like political unity was achieved; yet it does not appear that these great rulers dispossessed of their territories the princes whom they subdued, but only made them tributary, and after their death things reverted to their previous condition. Rezin, a slave, then made himself master of Damascus, and extended the Damascene monarchy over all northern and central Syria; but the conquests of Tiglath-Pileser resulted in its becoming a province of the Assyrian empire. Subsequently the whole land, including Palestine, became part of the successive empires of Babylonia, Media, Persia, and Macedonia. Then followed the dynasty of the Seleucidæ (q.v.). After their fall Syria passed into the hands of the Romans, who retained it, though not continuously—for on several occasions the Persian Sassanidæ (q.v.) managed to wrest it from them—until the Arab conquest (7th c. A.D.). During the crusades (q.v.) of the middle ages several Christian principalities were established here, but endured only for a short period. Syria now became a possession of the sultans of Egypt, in whose time it was frightfully devastated by the Mongols. In the 16th c. it was conquered by the Turks, and has ever since formed part of the Turkish empire.

SYRIAC. I. The language is a dialect of the Aramean, anciently spoken throughout Syria, the form preserved in literature being probably that of Edessa. After the Mohammedan conquest, 636 A.D., it was gradually displaced by the Arabic; and since the 13th c. it has been used only as an ecclesiastical language in the Syrian churches, and spoken corruptly in a few districts of mount Lebanon and on lake Oroomiah. This last has by the labors of the American missionaries been made a written language. The Syrian alphabet contains 22 letters, all consonants, read from right to left, and 5 vowels denoted by diacritical points. In grammar it shares the Aramaic peculiarities; its

vocabulary contains Persian, Greek, Latin, Arabic, Tartar, and even French and English words—traces of the nations that have ruled Syria. II. The literature corresponding to the condition of the country—which was continually subject to foreign dominion—has no freshness, is made up of translations, and largely on religious subjects. It may be divided into three periods: I. *Before the Mohammedan conquest, 636.* Syriac was then a spoken language, and the universities of Edessa and Nisibis were famous through the east. It produced the Peshito (i.e. the simple) version of the Bible, the oldest Syriac book extant, and accepted among all parties in the Syrian church. The Old Testament version was made by Christian translators directly from the Hebrew, and the New was made at Edessa in the 2d c., or the beginning of the 3d. II. 613–1318 was the period of decay; at the beginning Syriac and Arabic were both spoken, and at the end both were used in books. III. *From 1318 to the present time.* Arabic is the spoken language; and Syriac is cultivated only as an ecclesiastical language, and chiefly in the Maronite college at Rome.

SYRIAC VERSIONS. Apart from the Peshito (q.v.), there were other Syriac versions of the Old Testament current among the Syrian Christians, although they did not acquire canonicity among them. These were chiefly translated from the LXX., and the best known among them is one drawn up from the text of the Hexapla (q.v.; compare also ORIGEN), which it follows most slavishly, without any regard for Syriac idiom or grammar. It contains the critical marks of Origen, and is moreover furnished with numerous variants, fragments from other Greek versions, and exegetical scholia. Bishop Paulus of Tela is supposed to have composed it at the instigation of bishop Athanasius, 617 A.D. There are now only a few (imperfect) MSS. extant of it—one in Paris, one in the Ambrosian library (a third, once in the possession of T. Masius, has disappeared), and further portions are found in the Nitrian collection in the British museum. The greater part of the Biblical books has been edited from it, but in separate publications. A complete edition is still a desideratum. An attempt is now being made toward a more complete edition of the Hexapla itself by a reconstruction of lost portions of the Greek, through the medium of the parallel Syriac passages preserved in this translation. Two other MSS. in the Paris library contain fragments of another Greco-Syriac version, by Jacob, bishop of Edessa, who, in 703 and 704 A.D., composed it from the Peshito and the above translation, which is probably to be understood in the sense of his having made a new recension of Paulus of Tela's work, corrected after the Peshito.

SYRIAN RITE, CHURCH OF, that portion of the oriental church which had its seat in Syria, and which was anciently comprehended in the patriarchate of Antioch, and (after that of Jerusalem obtained a distinct jurisdiction) in the patriarchate of Jerusalem. The Syrian church of the early centuries was exceedingly flourishing. Before the end of the 4th c., it numbered 119 distinct sees, with a Christian population of several millions. The first blow to the prosperity of the Syrian church was the fatal division which arose from the controversies on the incarnation. See MONOPHYSITES, NESTORIANS, EUTYCHES, JACOBITES. The Eutychian heresy, in one or other of its forms, obtained wide extension in Syria; and the usual results of division ensued in the corruption and decay of true religion. The Moslem conquest accelerated the ruin thus begun; and from the 7th c. downward, this once flourishing church declined into a weak and spiritless community, whose chief seat was in the mountains, and whose best security from oppression lay in the belief on the part of the conquerors of their utterly fallen and contemptible condition. Under the head MARONITES has been detailed the most remarkable incident in the later history of the Syrian church. This branch of the eastern Christianity, although for the most part divided from the orthodox Greek church by the profession of Monophysitism, took part with the Greeks in their separation from the w., under Michael Cerularius; and the reunion of the Maronites to Rome had the remarkable result of establishing side by side, within the narrow limits occupied by the Christians under the Moslem rule in Syria, two distinct communities, speaking the same language, using the same liturgy, and following the same rites; and yet subject to two different patriarchs, and mutually regarding each other as heretics and apostates from the ancient creed of their country.

The chief peculiarity of the Syrian rite, as contradistinguished from the Greek, consists in its liturgy, and the language of that liturgy, which is Syriac, and with which the people, and in many cases the priests, are entirely unacquainted. The liturgy is known as the liturgy of St. James. The Syrians agree with the Greeks in the use of leavened bread, in administering communion under both heads, in permitting the marriage of priests (provided they marry before ordination), and in administering the unction of confirmation at the same time with baptism even to infants.

The Christian community of Syria may at present be divided into four classes: the Maronites, the Greeks (who are also called Melchites), the Monophysites, who are called Jacobites, and the primitive Syrian Christians (not Maronites), who are in communion with Rome. This last-named community forms the small remnant of the ancient Syrian church, which remained orthodox during the controversy on the incarnation, at the time of the general lapse into Monophysitism. To these are to be added the Christians of the Latin rite and a few Protestants. The Maronites number about 160,000; the Greeks are said to be about 180,000; the Jacobites of Syria and of Armenia proper are said to

reckon together about 40,000 families, of whom, however, probably scarcely 10,000 can be set down to the account of the Syrian church. The non-Maronite Syrians who follow their national rite, but are in communion with Rome, are supposed to amount to about 5,000. The resident Latins are chiefly members of the religious orders who from immemorial time possess convents in the Holy Land, and European Catholics, who have settled permanently, or for a time, at Jerusalem, Beirût, and Damascus. None of these can in any way be regarded as belonging to the Syrian church. It may be well to add, that the belief, and in most particulars the disciplinary practice of these several classes coincide substantially with those respectively of the same communities in the other churches of the east. All (with the exception of the Maronites and the few united Syrians of the Greek communion) reject the supremacy of the Roman see. The Syrians of the Greek communion reject the double procession of the Holy Ghost; and the Jacobites firmly maintain their old tenet of Eutychianism. Among them all are to be found monks and religious females. All enforced celibacy on their bishops, and refuse to priests the privilege of contracting a second marriage, or of marrying after ordination. The practice of fasting prevails among all alike. They receive and practice the invocation of saints and prayers for the dead, and the use of painted, although not of graven images. Many particulars regarding them are to be gleaned from the memoirs of recent missionaries of the several denominations, among which the letters published from time to time by the French society for the propagation of the faith, are particularly full. For the modern Nestorians, and the Syrian Christians of Travancore, see NESTORIANS.

SYRINGA, a genus of plants of the olive family (order *oleaceæ*). The English name of the genus is lilac (q.v.), and is derived from *lilug*, the Persian for flower. *Syringa vulgaris*, the common lilac, is a native of Persia, Hungary, and the borders of the Danube. Dr. Sibthorp found it wild on mount Hæmus, but not in Greece. It has been long cultivated by the Turks. It is one of the few shrubs that are not injured by the smoke of cities, and it flourishes in perfection in most of the squares of London. It grows very fast, from 20 to 36 in. every year. The Persian lilac, *S. Persica*, is a small shrub from 4 to 6 ft. high, and is one of the most ornamental of low deciduous shrubs. When planted in pots and forced, it may be made to flower at Christmas; but under the circumstances the flowers will lose their ordinary fragrance. There are three varieties of this species in the English nurseries. *S. Chinensis* is a native of China. It is intermediate between *S. vulgaris* and *S. Persica*. It grows vigorously to a height of from 10 to 12 ft. The *lilas de Marly* and *lilas Sangé* are varieties. *Syringa* is also a name improperly applied to the mock-orange or Philadelphus (q.v.).

SYRINGE (Gr. *syrix*, a pipe), a hydraulic instrument, consisting of a cylinder of metal or glass, having a conical nozzle at one end, and the other fitted with an air-tight piston. The nozzle being inserted in a liquid, the retraction of the piston draws the liquid into the cylinder, on the principle of the pump (q.v.), and by its forward pressure the liquid is expelled from the nozzle in the form of a jet.

SYRRHAPTÈS, a genus of birds of the grouse family (*tetraonidæ*), of which only one species is known (*S. Pallasii*), a native of the deserts of Tartary, abundant in the neighborhood of lake Baikal. From its peculiar characters, which led Pallas to call it *tetrao paradoxus*, it has received the somewhat pedantic name of *heteroclitæ grouse*. (A word is called *heteroclitæ* by grammarians which departs from the ordinary forms of declension.) The legs and toes are short, and densely feathered; and the toes are joined together for the greater part of their length. The bird walks with difficulty, but flies very well, although in general only for short distances. The wings and tail are very long, terminating in remarkably long, slender, pointed plumes.

SYRTIS MAJOR AND SYRTIS MINOR, the ancient name of two gulfs of the Mediterranean sea, on the n. coast of Africa. The former (now called the *gulf of Sidra*) lies between cape Mesurata, in Tripoli, and the table-lands of Barca, and forms the most southern part of the Mediterranean. The latter (now called the *gulf of Cubes*) lies to the n.w., between Tunis and Tripoli. The shores of both are inhospitable, and abound in quicksands, which, carried by the wind, are said by the ancients to have frequently overwhelmed ships, and the reports of modern travelers to some extent confirm these old traditions. Their waters are (or were) dangerous to sailors, on account of the shallows, sand-banks, and sunken rocks that abound in them. The name Syrtis is derived from an Arabic word *sart*, meaning a desert.

SYRUP, *sirup*, *sherbet*, and *shrub* are all derived from the Arabic *srb*; the first through the Latin, the second through the Persian, and the third through the Hindu. Syrup, in its simplest meaning, is a saturated solution of sugar boiled to prevent fermentation; but it also means the juice of fruits saturated with sugar and many flavored liquors, treated in the same way. Generally speaking, the finest refined sugar is used; and every effort is made to get the syrup very clear and free from all feculent matter. Syrups of fruits are much used on the continent to mingle with water for drink, and are very wholesome. They are also used in Britain, but not much, except in medicine—there being many medicinal syrups.

SYSTYLE, an arrangement of classic columns in which the intercolumniation is equal to twice the diameter of the column.

SYZRAN', a t. of central Russia, in the gov. of Simbirsk, on the right bank of the Volga, about 150 m. below the t. of Simbirsk. It owes its foundation to its advantageous commercial position on the Volga, and in the middle of a district teeming with agricultural produce. From the wharfs of Syzran, 150 vessels, laden with corn, are annually dispatched to Rybinsk and St. Petersburg. Pop. '67, 19,279.

SZABADKA. See *THERESIOPEL*, *ante*.

SZABOLCS, a co. in n.e. Hungary, bounded on the n. by the Theiss river, about 2,800 sq.m.; pop. '70, 265,584. The surface is level, with large areas of marsh. The soil is sandy, but fertile. The principal productions are corn, cattle, and wine. Capital, Nagy-Kálló.

SZAR VAS, a t. of Hungary, in the co. of Bekes, in a plain on the Kőrös, 22 m. n.e. from Csongrad. It has a considerable trade in corn and cattle. Pop. '69, 22,446.

SZATMAR', or **SZATHMAR'**, a co. in n.e. Hungary, s. of the river Theiss, drained by the Szamos river; about 2,250 sq.m.; pop. '70, 280,563. The surface is level, except in the east, where it is mountainous. There is a large area of marsh. The soil is fertile. The principal productions are corn, hemp, flax, tobacco, and wines. The inhabitants are mostly Magyars. Capital, Szatmár.

SZATHMAR-NEMETHY, a t. of Hungary, on the Samos, 60 m. n.e. of Debreczin; pop. '69, 18,353.

SZECHENYI, ISTVÁN, Count, 1792-1860; b. Vienna, of a noble and wealthy Hungarian family. He served in the Austrian army in the wars with Napoleon, and afterward traveled through Europe. Clearly seeing the great need for reform and advance in the material and social status of the Hungarian people, he gave liberally of both time and money in bringing this about. Among his acts were the endowment of the Hungarian academy; the founding of a society for improvement in horse-breeding, a most important occupation in Hungary; and the establishment of schools of acting and music. To his exertions were due the erection of the great suspension bridge between Pesth and Ofen, the removal of obstacles to navigation at the "Iron Gates," and the introduction of steamboats on the Danube. He became minister of public works. He opposed the revolutionary measures of Kossuth, and when the revolution of 1848 broke out, became insane, and though he recovered, continued to reside at the Döbling asylum, where he committed suicide after a domiciliary visit by the Austrian police.

SZE-CHUEN (Four streams), a vast province of western China, and the largest of the 18. It has an area four times greater than that of England, but the population is scanty. The Kincha-Kiang, or "Golden sanded river," which rises in the southern slopes of the great Tibetan range, flows through Sze-chuen, and after receiving several tributaries, it becomes, before leaving the province, the famous Yang-tse-Kiang. In its course, it passes at right angles and by narrow gorges, through a succession of ranges of hills, which have a direction from n. to south. The people of Sze-chuen cannot always force a subsistence from their stubborn soil. Famines are not uncommon, when whole families are starved to death, and thousands subsist on a mixture of rice, roots, and common earth. Coal is abundant, but of inferior quality; seams of from 3 to 5 feet in thickness are laid bare in the gorges cut by the Yang-tse, and gold is found in small quantities.

SZEGEDIN, till lately the second largest t. in Hungary, but almost completely destroyed by a terrible flood in Mar., 1879. In this hardly paralleled catastrophe, of the 7,000 houses of the city, only 350 were left standing. The ruin to property was immense; the loss of life was given at 2,000. Szegedin stands (or stood) on the low ground where the Theiss is joined by the Maros, 118 m. s.e. of Buda-Pesth. In its normal condition, it manufactures great quantities of soda, tobacco, coarse cloth, etc., has the largest wharfs on the Theiss, and carries on an extensive river-trade in wood and corn with Transylvania. Its markets rank next to those of Pesth and Debreczin. Pop. '69, 70,179.

SZEGSZARD, a t. of Hungary, near the right bank of the Danube, 80 m. s.s.w. of Pesth. Here excellent red wine is made. Pop. '69, 11,069.

SZENTA. See *ZENTA*.

SZENTES', a market t. of Hungary, 30 m. n. of Szegedin, near the left bank of the Theiss. The commune contains (1869) 27,653 inhabitants, who are chiefly engaged in the wine culture.

SZOLNOK, a co. in Hungary, bounded on the s.e. by Transylvania, within which it was formerly included, drained by the affluents of the Szamos river, about 850 sq.m.; pop. '76, 113,639. The surface is mountainous and well wooded. The soil in the valleys is fertile. The principal productions are corn, rye, oats, tobacco, and wines. The inhabitants are mostly Wallachians. Capital, Szilágy-Somyló.

SZOLNOK', a t. of Hungary, on the Theiss, 66 m. e.s.e. of Pesth. It contains important salt magazines, and is the center of the traffic by steamers on the Theiss, and an important railway station. Pop. '69, 15,847.

T

T, THE twentieth letter of the English alphabet, is the sharp or mute of the lingual series, *t, d, th (dh)*. It is produced by pressing the fore-part of the tongue against the front of the palate. The name in Shemitic (*Tau*) signifies a mark (in the form of a cross.) The Shemitic tongues had another *t*-sound, which became the Greek *ϑ (th)*. This aspirated *t* is wanting in Latin and its derivatives; it is also foreign to high-German, although the Gothic and other low-German tongues (English) possess it. The Gothic *th* has become in high-German *d*. In the *spelling* of high-German, *th* occurs not unfrequently; but it is never pronounced, and the introduction of it being considered by students of the language an aberration, there is a tendency to drop the *h*. There is evidence that in Latin, at an early period, *t* before *i* was sibilated so as to sound like *ts* or *z*. See letter C. Before *s*, *t* was frequently dropped; as *fons* for *fontes*, *sors* for *sortes*. Final *t* was in Latin pronounced but faintly, and inscriptions show that in popular speech it was often dropped; e.g., *fecit* for *fecit*, *vixit* for *vixit*. Thus the modern Romanic languages have inherited the loss of the pronominal ending *t* from their common mother. In French, *t* between two vowels has been elided; as *père mère*, from *pater, mater*. In the corresponding words of the allied languages, *t* is often interchanged with other letters. T in Sanskrit, Greek, and Latin becomes *th* in Gothic and English, and *d* in high-German; thus Lat. *tres* (Sans. *trayas*), Goth. *thraiz*, Eng. *three*, Ger. *drei*; Lat. *tectum* (Gr. *tegos*), Goth. *thak*, Eng. *thatch* or *thack*, Ger. *dach*; Lat. *frater*, Goth. *brothar*, Eng. *brother*, Ger. *bruder*. In German, the *t* of the English is often represented by *z*, as Eng. *two* = Ger. *zwei*; Eng. *toll* = Ger. *zoll*; while German *t* or *th* becomes Eng. *d*, as Ger. *tag*, *thau* = Eng. *day*, *deu*. A more remarkable interchange is seen in Lat. *lacrima* = Eng. *tear*. See PHILOLOGY.

TABASCO, a state in s.e. Mexico; bounded on the n. by the gulf of Mexico, on the e. by Campeachy, on the s. by Chiapas and Guatemala, and on the n. by Vera Cruz; drained by the Tabasco, the Usumasinta, and other streams; about 12,500 sq. m.; pop. '71, 83,707. The surface is mostly low and level, with a large area of marsh. The climate is very hot and unhealthful. Mahogany and other valuable woods abound. The principal productions are rice, tobacco, coffee, sugar-cane, pepper, indigo, and honey. Capital, San Juan Battista.

TABANIDÆ, a numerous family of dipterous insects, of the section *proboscideæ*, which live by sucking the blood of horses, oxen, and other animals, and are popularly known by the name of GAD-FLY, which, however, is often given also to some of the *æstridæ* (see Bor). The insects called cleg (q.v.) are of this family. The proboscis is exerted, and is generally terminated by two lips; the palpi are also exerted; the antennæ are three-jointed, the third joint consisting of a number of rings. The tabanidæ fly with a buzzing noise. They are very annoying to cattle in the end of spring and early part of summer; and where they abound, the skins of cattle are often streaked with blood from their bites. The LARGE GAD-FLY (*T. borus*) is more common in some parts of the continent of Europe than anywhere in Britain, and is rarer in Scotland than in England. But the British tabanidæ are numerous. The species are widely distributed. Some of them inhabit the deserts of Arabia and Africa, and attack camels in prodigious numbers.

TABARD (Fr. *tabarre* from *tabardum*, low Lat.), a military garment in general use in the latter half of the 15th and beginning of the 16th c., which succeeded the *Jupon* and *Cyclas*. It fitted closely to the body, was open at the sides, had wide sleeves or flaps reaching to the elbow, and displayed the armorial ensigns of the wearer on the back and front, as well as on the sleeves. About the middle of the 16th c., the tabard ceased to be used except by the officers at arms, who have down to the present time continued to wear tabards embroidered with the arms of the sovereign.

TABASHEER, a substance sometimes found in the cavities or tubular parts of the stems of bamboos and other large grasses. It consists chiefly of silica, with a little lime and vegetable matter, or sometimes of silica and potash, in the proportions of about 70 parts of silica and 30 of potash. It appears to be formed by extravasation of the juices of the plant, in consequence of some diseased condition of the nodes or joints. It is in high repute among the Hindus as a tonic, and is prepared by imperfect calcination and trituration. The powder is often chewed with betel, in order to renovate the constitution. There are several varieties of tabasheer, one of which, of very rare occurrence, is extremely beautiful, of a delicate azure color by reflected light, and of a faint yellowish hue by transmitted light, easily crushed between the fingers, and of "an ærial and unsubstantial texture, which we look for in vain in any other solid." Other varieties are yellowish, white, and much like some varieties of opal. Tabasheer is very porous, and absorbs water and oil very rapidly; effervescence taking place when it is plunged in water. By absorption of oil, the opaque varieties become transparent. When the greater part of the oil is expelled by heat, the structure of the tabasheer becomes apparent; it is beautifully veined, the veins being sometimes parallel, and sometimes curved.

The optical properties of tabasheer are remarkable. Of all known substances, it has the lowest refractive power.

TABBY, or **TABBYING**, another name for watering fabrics. See **MOIRE**. It is usually applied to stuffs or worsted cloths instead of silks.

TABERNACLE (Heb. *Ohel Moed* = tent of meeting, *seil.*, between God and man; **LXX.** *Skene*, Vulg. *Tabernaculum Fuderis*), or, more fully, "tabernacle of the congregation," was the tent first erected by Moses in the desert as a visible symbol of the divine Presence in the midst of the people. It was the place where he went to receive his inspirations as their representative when they "came to seek Jehovah." A cloudy pillar descended and stood at the door of the tabernacle while "the Lord spake to Moses." The detailed description of the tabernacle contained in Ex. xxv. seqq., xxxvi. seqq., renders more than a brief outline superfluous in this place. Suffice it to mention that it was divided into the "sanctuary" proper—which formed the front part, and the dimensions of which were 20 cubits in length, 10 in width, and 10 in height—and the "holy of holies," which was 10 cubits square and 10 high. A kind of court-yard, formed by curtains suspended between columns, ran round the tabernacle, 100 cubits long and 50 wide. The entrance was toward the east—the rising of the sun—and closed by another costly curtain, into which, like unto the first covering, figures of "cherubim" were woven. The surrounding court was much larger on this eastern than on the western side, for here it was that the people assembled for the purpose of worship. Here also stood the altar, made of acacia-wood, upon which a perpetual fire was kept burning, and the brazen laver. The *sanctuary* contained the gilded table with the showbread to the right, the golden candlestick with the seven branches to the left, and between both the "golden altar," or the "altar of incense," upon which the high-priest burned incense in the morning and evening. In the holy of holies, the holy ark, or ark of the covenant, alone was kept; a box of acacia-wood, plated with pure gold both in and outside, containing the two tables of the Ten Commandments. On the top of it were the two cherubim, their faces turned toward each other; and between them there was the symbolical presence of Jehovah (the Shechinah), to which Moses appealed for guidance.

Only once a year, on the Day of Atonement, the high-priest was allowed to enter the holy of holies, while the sanctuary was the ordinary place of the priests, and the court that of the Levites. The tribe of Levi was also that to which the place nearest to the tabernacle, around which the 12 tribes were grouped, was assigned, as it also was the duty of its members to convey the building from place to place during the migrations.

The tabernacle, after the people had settled in Canaan, was erected at Shiloh, where it was still found at the time of Saul, although the ark of the covenant itself had been carried away by the Philistines, in the time of Eli, and when restored, placed at Kirjath-jearim. Nor was the tabernacle of Shiloh the only sanctuary, as it was intended to be. We find other local sanctuaries with priests—at Bethel, Nob, Sichem, Mizpah, etc.—at which even Samuel worshiped, as in legally instituted places. When David is reported to have removed the ark from Kirjath-jearim to Jerusalem, nothing is said about the tabernacle of Shiloh; on the contrary, David erected a new one on purpose for the ark. It seems probable that it was removed at some time or other from Shiloh to Nob, and thence to Gibeon, from whence Solomon seems to have fetched it away, with all its vessels, thus putting an end to the double worship that under David had divided the faithful between Gibeon, where Zadok officiated, and Jerusalem with Asaph's worship. Nothing is further known of the tabernacle, which, besides being a symbol of God's presence, had also served the purpose of a visible political and religious link between the tribes. As a safeguard against idolatry and unlimited sacrificial worship, however, it did not prove effective enough.

TABERNACLE, (Lat. *tabernaculum*, *armarium*), in the Roman Catholic church, is the name given to the receptacle in which the consecrated elements of the Eucharist are retained. The name is derived by analogy from the tabernacle of the old law, and in form the Roman Catholic tabernacle bears a general resemblance to the Jewish original. By the present discipline, the tabernacle is commonly a small structure of marble, metal, or wood, placed at the posterior part of the altar, and of costly material and workmanship. Even when the exterior structure is of marble or metal, there is commonly an inner receptacle of wood (properly cedar), lined with silk. The tabernacle is appropriated exclusively to the reservation of the Eucharist, and it is prohibited to keep within it any other object, however sacred, as the chrism, relics of saints, the altar vessels, etc. A lamp is constantly kept burning before the tabernacle, which is ordered to be kept at all times carefully locked, the key being retained by the clergy, to whom it is forbidden to intrust it to any lay person, even the sacristan or other official of the church.

TABERNACLES, FEAST OF (Heb. *Succoth*, **LXX.** *Heorte skenon*, Vulg. *Feria tabernaculorum*), a Hebrew feast of seven days' duration, beginning on the fifteenth day of the seventh month (Tishri), and instituted principally in memory of the nomad life of the people in the desert, and the booths or tents used on their march. Besides this signification, it also had an agricultural one, like the other two pilgrimage festivals, the passah and the feast of weeks. It was emphatically the feast of "ingathering"—i.e., the close of the labors of the field—the harvest of all the fruits, of the corn, the wine, and

the oil. During this feast, the great bulk of the people were enjoined to dwell in booths, which we learn from Nehemiah viii. 15, were made of olive, pine, myrtle, palm, and other branches, and were erected on the roofs of houses, and in the courts and streets. The scriptural injunction, to take trees and "boughs of goodly branches of palm trees," etc., was by tradition explained to mean a bunch made of palm, myrtle, and willow branches, and the esog-fruit, a species of citron which the faithful carried in procession during these seven days in the temple; while those who did not visit the temple only said a benediction over it on the first day. The Sadducees and Karaites, however, demurred to this explanation, taking the passage merely to refer to the construction of the booths. Special sacrifices, and a greater number of burnt-offerings than on any other festival, were offered up on this; and on it also the law was to be read to the people every seventh year. It was emphatically called *the* festival, and was the most joyous of them all. There was especially, during the time of the temple, the "joy of the libation," consisting of the priest's fetching, during the morning sacrifice of each day, water from the well of Siloah, and pouring it out, with the accompaniment of music and hymns. There was further a grand illumination in the evening in the court of women, which is said to have lighted up the whole city of Jerusalem; and during and after which, dancing and singing took place. On each day the trumpets were sounded 21 times. At the end of the seven days' joy, an eighth day of solemn rest was celebrated, which was perfectly distinct from the other days both in its sacrifices and in its general service. The bunch was laid aside, the booths were relinquished, and a sin offering—in expiation of transgressions that might have taken place during the hilarity of the previous feast-days—was slaughtered.

Three distinct times we find the inauguration of the temple celebrated on this important festival, by Solomon, Ezra, and Judas Maccabæus, although with regard to the festival itself it would seem from Nehemiah viii. 17, that it never had been properly celebrated before the exile. The observances of the booths and the harvest-bunches are still in force with the strict adherents of traditional Judaism, although the agricultural signification of the festival to them can only be a historical or poetical reminiscence. It has been well observed of old, that no festival could have been more apt to inculcate the fundamental principle of Judaism—viz., the equality of all men, than this, which enjoined that every one should live for a time in primitive dwellings, without distinction of rank, or station, or fortune, and should rejoice in the fruits of the last harvest on the hallowed spot, together with the whole people of the land, "before the Lord."

TABERNÆMONTANA. See COW-TREE and FORBIDDEN FRUIT.

TABES DORSALIS, an affection of the nervous system, now known in medicine as *locomotor ataxy*. Tabes dorsalis was so named by Romberg of Berlin; but Dr. Todd of London in 1847 first recognized its true nature, and specially insisted on the distinctions to be drawn between tabes dorsalis and *paraplegia* (see PARALYSIS). The name of *locomotor ataxy* was first applied to the affection by Dr. Duchenne of Paris. It is characterized by a want of power in harmonizing the action of certain muscles, the absence of such co-ordinating power being first apparent in the lower extremities, and the gait in consequence being straggling and unsteady. True paralysis is absent, but sensibility is diminished, and neuralgic pains are present in the legs and feet. The loss of power progresses, and the later stages of the malady are marked by such symptoms as disordered vision, incontinence of urine, and exhaustion. The duration of this disease varies. It may run its course in a few months, or be prolonged over years. The *etiology* or *causes* of tabes dorsalis are still obscure. Mr. Lockhart Clarke has shown that a peculiar change in the posterior columns of the spinal cord, and in the posterior or sensory roots of the spinal nerves, accompanies this disease. Prolonged exposure to cold and damp, drunkenness, sexual excesses, masturbation, and like causes have been credited with inducing the disease. It is alleged to be more common in males than in females, and subjects between the ages of 30 and 50 are said to suffer most frequently from its attack. The characteristic movements in tabes dorsalis are worthy of note. The patient has an unsteady gait, and walks like a drunken person, but soon recovers his bearing in some degree. A difficulty in carrying out the intents of the will is experienced, and in picking up an object one hand is employed to steady the other. When the eyes are shut, the patient walks with extreme difficulty. Tabes dorsalis may be distinguished from disease of the cerebellum by the absence of the characteristic pain at the back of the head, and vomiting. The *prognosis* of tabes dorsalis is very unfavorable. Its progress may be retarded, but the prospect of ultimate cure is well nigh hopeless. The *treatment*, as may readily be understood, is limited to the improvement of the general health, rather than to any specific remedies. Warm clothing, nutritious food, and rest are the chief items in the course of treatment prescribed for this disease; while opiates are indicated for the relief of the neuralgic pains. Sulphur baths have been prescribed in the earlier stages to relieve the numbness, and attention requires to be paid to the bowels with a view of alleviating constipation.

TABINET, a rich kind of cloth, chiefly used for window-curtains. It consists of a warp of silk and a weft of wool-yarn, of the same kind as that used in making poplin. It has the appearance of a fine damask, and is usually enriched with diaper patterns.

TABLEAUX VIVANTS (i.e., living pictures), representations of works of painting and sculpture, or of scenes from history or fiction, by living persons. They are said to have been invented by Mme. de Genlis, when she had charge of the education of the children of the duke of Orleans. They have long been common in theaters, and have more recently become an amusement of private circles. In an æsthetic point of view, they are of no value whatever, but rather are of injurious influence, and contrary to just principles of taste.

TABLE-LANDS, or **PLATEAUS**, are extensive plains at a considerable elevation above the sea, whose boundaries are either ranges of mountains much higher on the side away from than on the side next to the table-lands; or steep acclivities, sloping from the level of the plateaus to the surrounding country. They are often traversed by mountain chains, and occasionally even lose the character of plains altogether, being mere conglomerations of hills. The chief table-lands are in Europe, central Spain; in America, the Oregon territory, the great salt plain of Utah, the north and center of Brazil; in Africa, the interior of Barbary; while in Asia, almost the whole of the south and center of the continent consists of plateaus, which rise terrace above terrace till they culminate in that of Thibet. Of the Asiatic plateaus, the principal are: that of Asia Minor (3,280 ft. above sea-level), Armenia (7,000 ft.), Persia or Iran (3,000 ft.), Mysore (4,000–5,000 ft.), Deccan (1500–2,000 ft.), Thibet (12,000–17,000 ft.), and Chinese Tartary (3,000–4,300 ft.). These table-lands are generally accounted for by the supposition of a more extensive and uniform action of the upheaving force than that which produced mountains; and satisfactory indications of the former action being quite recent, and long subsequent to the latter, are occasionally discovered.

TABLE-MONEY is an allowance granted to general-officers in the army, and flag-officers in the navy, to enable them to fulfill the duties of hospitality within their respective commands. It varies according to the locality or importance of the appointment, £3 3s. a day being the maximum, except under very unusual circumstances.

TABLE MOUNT. See CAPE TOWN.

TABLES, **LUNAR**, are tabular lists of the values of the elements of the moon's orbit, as planetary tables are those of the elements of the planets' paths; but the term is also occasionally employed to denote the tabulated angular distances of the moon from certain stars at fixed epochs, as given in the *Nautical Almanac* (q.v.). See **LATITUDE**.

TABLE-TURNING. See **ANIMAL MAGNETISM**; **SPIRITUALISM**.

TABOR, a celebrated mountain of northern Palestine, rising solitarily in the north-eastern part of the plain of Esdrælon, to about the height of 1000 ft. and commanding the most extensive and probably the most magnificent prospect in the Holy Land. Eastward, the eye catches a gleam of the waters of the Galilean sea, 15 m. distant; while the whole picturesque outline of its deep-sunken basin, of the rolling trans-Jordanic plateau, and the course of the sacred river itself, is clearly traceable; westward, stretch away into the dim horizon the rich plains of Galilee, rising up into the dark-green ridges of Carmel, overhanging the Levant; on the north and north-east, the snow covered heights of Hermon (see **LEBANON**) glitter pale over the intervening hills; while to the south, the view embraces the fatal heights of Gilboa and the confused landscapes of Samaria. Tabor itself is at present thickly clad with forests of oak, pistacias, etc., the haunt of wolves, wild-boars, lynxes, and various kinds of reptiles. Its beauty alone would be sufficient to insure it distinguished mention among the mountains of Palestine, but it owes its celebrity even more to its having been regarded from an early period as the mount of Transfiguration. This opinion, however, is now all but universally abandoned, as there is strong evidence of its summit having been then occupied by a city; and travelers are disposed to look for the scene of this supernatural incident further north, in the neighborhood of Hermon. In the times of the crusaders, Tabor was studded with churches and monasteries, relics of which, as well as of Roman and Saracenic structures, still remain.

TABOR, a small drum, played with one stick, in combination with a fife. It was formerly used in war, but has now given place to the kettle-drum.

TABORITES (a sect of the Hussites in Bohemia), derived their name from their fortress of Tabor, near the river Luschnitz, an affluent of the Moldau, 49 m. s.s.e. of Prague. There is now a small town at the place, which has a population of 6,717, and carries on some wollen manufactures, etc.—The first leader of the Taborites was John Ziska (q.v.) of Trocnov. Under him was Nicolas von Hussinecz, who repelled the imperial army from Tabor in 1420. The Calixtines, desirous of the peace of the country, offered the throne of Bohemia first to king Ladislas of Poland, then to the grand duke Witold of Lithuania, and afterward to his brother Coribut. Ziska refused his consent, and thus these parties became completely separated. In the years 1420 and 1421 both of them set forth their creed in a number of articles. The Taborites absolutely rejected all ordinances of the church not expressly appointed in the holy Scriptures. Both parties were united by common danger in opposition to a common enemy. In 1422 Ziska defeated the imperialists at Deutschbrot, and thereafter with uninterrupted success in a number of minor conflicts; and in 1424 Prague was saved from destruction only by submitting to hard terms of peace. After Ziska's death, Procop (q.v.) the

greater, or Procop rasa (the shaver), and Procop the less were the leaders. In 1427 and in 1431 they gained great victories at Miess and Tachau over the mercenary crusaders of the German empire, and till 1432 their incursions were the dread of the neighboring countries. The council of Basel, finding them still unconquered in 1433, proceeded to treat with them; and the Calixtines entered into an arrangement, known as the *Prague compact*, which, however, was despised by the Taborites and the Orphans, as that section of the Taborites who considered Ziska as irreplaceable, had come to be termed. The Taborites and Orphans were completely defeated at Böhmischbrot on May 30, 1434, by the now united forces of the Roman Catholics and the Calixtines. In the treaty of Iglau in 1436, the emperor Sigismund confirmed the compact, and promised religious and political liberty. The civil war, however, continued till king Ladislas in the diet at Kutenberg, in 1485, established a religious peace, securing both Roman Catholics and Calixtines in their possessions. The Taborites were eventually lost in the sect of Bohemian Brethren (q.v.), which arose from among them.

TABRIZ (pronounced and frequently written *Tabreez*), a great and ancient city of Persia, capital of the province of Azerbaijan, 40 m. e. of lake Urmiah, and on the Aji, which flows s.w. into that lake. The town is surrounded by a ditch and a brick wall, pierced by 7 gates. It forms an oblong of gardens and houses, 2½ m. long; stands 4,000 ft. above sea-level, but nevertheless has the appearance of being shut in by mountains. The streets are broader and cleaner than in most eastern cities, but they are flanked as usual by the pits from which the earth required for their houses was taken; the houses are infested with noxious insects; and the bazaars are roofed with sticks, and are dark and dirty. Water, however, is comparatively plentiful. The chief buildings of Tabriz are not specially striking. Perhaps the principal architectural feature of the town is the fine ruin, Kabūd Masjid, or "blue mosque," about 300 years old, and in part covered with blue tiles beautifully arabesqued. The citadel is a spacious edifice of burned brick, the walls of which, however, have been cracked in many places by earthquakes. Tabriz is the seat of a varied industry, in which leather and silk manufactures, and gold and silver smith's work alone are of importance; recently it has also become the emporium of an extensive trade, the exact value of which, however, is not known, owing to the careless manner in which the custom-house officials transact their business, and to the prevalence of smuggling. Merchandise, to the value £400,000 is exported through the regular channels from Tabriz to Russia; but it is estimated that in 1859 a quantity of equal value was conveyed to that country by smugglers. Since 1859 this illicit traffic has very much diminished, although it still exists along the whole Russo-Persian frontier of Azerbaijan. The chief imports are cotton fabrics, sugar, woollen cloth, and wines and spirits. The chief exports are cotton cloths (originally from England), drugs and spices, dried fruits, shawls, carpets, and raw silk. The commerce of 1877-78 was very small, mainly on account of the Russo-Turkish war, which arrested the trade between Trebizond and Tabriz. The imports were in that year valued at £525,500, the exports at only £270,000; while in 1873-74 the collective trade amounted to over £7,100,000. The Anglo-Indian telegraph line passes through the city.

Tabriz, the ancient *Tauris*, became the capital of Tiridates III., king of Armenia, in 297 A.D., and was probably at that time an old city. In 791 A.D. it was enlarged and greatly embellished by Zobeïdah, the wife of Harūn-al-Rashid. In 878, and again in 1041, the city was devastated by an earthquake. It was taken and sacked by Timur in 1392, and was soon after seized by the Turkomans, from whom it was taken by the Persians in 1500. In 1721 it was again visited by a dreadful earthquake, and on this occasion 80,000 persons are said to have perished. It has been several times in the hands of the Turks, but was finally taken from them by Nadir shah in 1730. Tabriz is a city of Turks, and Turkish is the language spoken. Pop. variously estimated at 110,000 to 180,000.—Eastwick's *Three Years' Residence in Persia* (Lond. 1864), and *Commercial Reports from Her Majesty's Consuls* (1878).

TABU, **TAPU**, or **TAMBU**, a Polynesian term, denoting an institution found everywhere, and always essentially the same, in the Polynesian islands and in New Zealand. Its primary meanings seem to be exactly the same as those of the Hebrew *to'ebah*. This word, like the Greek *anathema*, the Latin *sacer*, and the French *sacre* (and the corresponding and similar terms in most languages), has a double meaning—a good sense and a bad; it signifies on the one hand, sacred, consecrated; on the other hand, accursed, abominable, unholy. It results from a thing being held sacred, that certain acts are forbidden with reference to it, and from any act being deemed abominable, that it is forbidden: a notion of prohibition thus attaches to the word tabu, and this is in many cases, the most prominent notion connected with it. The term is often used substantively in the sense of a prohibition, a prohibitory commandment. If a burial ground has been consecrated, it is tabu; to fight in it is then an act sacrilegious and prohibited, and this also is tabu; moreover, those persons are tabu who have violated its sanctity by fighting in it, and they are, loosely and popularly, said to have broken the tabu. This example illustrates all the uses of the word. It has furnished to the English language the now familiar phrase of being "tabooed" = forbidden.

The extent to which, among the Polynesians and New Zealanders, things and acts are tabu, must appear almost incredible to Europeans unaware of the facts of savage life.

Without much detail, it is impossible to convey any idea of it. The prohibitions, however, divide into two classes: one consisting of traditional rules, binding upon all, acting through religious terror equally upon chiefs and people; the other, of prohibitions imposed from time to time, obviously with the view of maintaining or extending the authority of the chiefs. Those of the first class are by far the most remarkable. Of the most important of them—those bearing upon what are called sacred things, those relating to the person of the chief, and those relating to intercourse between relatives—a few examples may be given.

Any house or piece of ground consecrated to a god is tabu, and thus affords an inviolable shelter to men fleeing from an enemy. *A fortiori*, all temples are tabu. To sit upon or to touch the threshold of a temple is tabu to all except chiefs of the first order, the lesser chiefs may stride over the threshold, but common persons pass over it on their hands and knees. It is tabu to eat the plant or animal believed to be the shrine of one's tutelary god. To come in the way of a funeral procession is severely tabu, for it is believed that the gods accompany the procession; if any person were to disregard the warning chant of the mourners, they would rush at him and put him to death. Again, to touch the person of a chief is tabu to his inferiors; also, to touch anything belonging to him, to eat in his presence, to eat anything he has touched, or to mention his name. And a chief's threshold is as sacred as that of a temple, and must be passed over in the same manner. It is strictly tabu to touch a dead chief or anything which belonged to him, or any of the clothes or utensils employed in his interment; even those employed in laying out the body pay the penalty of infringing this prohibition. The interdiction upon family intercourse varies in extent in different places. In the Tonga islands it was tabu to mention the name of father, mother, father-in-law, mother-in-law; also to touch these relatives, to eat in their presence (unless with the back turned, when constructively the person was not in their presence), or to eat anything which they had touched. In the Fiji islands, generally, it is tabu for brother and sister, first cousins, father-in-law and son-in-law, mother-in-law and daughter-in-law, brother-in-law and sister-in-law, to speak together, or to eat from the same dish. Husband and wife, too, are forbidden to eat from the same dish. In some places a father may not speak to his son after he has passed his 15th year. In an immense number of cases, equally extraordinary, the tabu is used to enforce the prevailing ideas of social propriety. It interferes with cooking, eating, dressing, speaking; scarcely anything is too minute to be regulated by it.

The traditional tabu also supplies to some extent the place of laws and a police. In many places exposed property of some kinds is always under its shelter. In some cases it appears to have been worked in the interest of the priests; thus, certain foods—for example, turtle—are always tabu, and cannot be eaten until a portion has been set aside for the gods. There is a purely superstitious use of it, too, in relation to common things, as when a canoe is made tabu that it may go more safely.

The chiefs have a large discretionary power of declaring articles or actions tabu; indeed, their power is unlimited, but they are expected to keep within precedent. In many cases they use it for purely public purposes—thus, when a feast is coming on they lay a tabu upon pigs and nuts, and other articles, that there may be abundance for the feast. And when a scarcity of anything is apprehended they place a temporary tabu on its use. Speaking generally, any article of food—fish, flesh, fowl, grain, or fruit—may be rendered tabu. A coast, a river, a hunting-ground, may be declared tabu; and then there is an end of fishing, and sailing, and hunting, until the chief has withdrawn the prohibition. The tabu is obviously a powerful instrument of government; and the chiefs are very adroit in using it for their own advantage.

When a man has accidentally infringed the tabu against touching a chief, or a relative, or things immediately connected with him, he is freed from the state of tabu by a ceremony called *moë-moë*; this consists in pressing, first the palms, then the back of the hands, to a superior chief's foot, and afterward washing the hands with water. If a man has accidentally eaten food which a relative or chief has left, he goes through a ceremony called *fota*, which consists in pressing a superior chief's foot against the stomach. Any breach of the laws relating to sacred places must be atoned for by sacrificing to the offended god. A person, when he is tabu, must not use his hands in feeding himself or in working; were he to feed himself, it is believed that he would die; he must be fed by others until the tabu is removed. In many cases the tabu can only be removed by time. Thus, a common person, who has touched a dead chief, remains tabu for ten lunar months; a chief for four or five months, more or less, according to the deceased's superiority over him. In several cases breach of tabu is punished with death; in many, it involves a sort of outlawry—the neighbors of the offender being free to carry off or to destroy his goods.

It is obvious that the effect of breaking a tabu—at any rate, one effect of it—is to produce uncleanness. The offender has done something unholy, accursed; his hands are not clean; if he has not sinned in the last degree he must make atonement or undergo purification. The chief, holding a divinely appointed rank, recognized as a semi-divine person, descended from the gods, is the medium of purification; he has authority to loose as well as to bind. The offense consists in a thing having been done displeasing to the supernatural powers, for which, it is believed, they will not fail to take

vengeance. It is not, in the general case, an offense against any particular god; nor is the punishment of it looked for from one god more than from another. Tabu is certainly older than most of the Polynesian gods; it must have existed for ages before the mythologies took their present shapes; it might have existed before any name for god had become current. It has no connection with fetishism. The Polynesians do not worship natural objects; their belief that certain plants and animals are the shrines of gods would naturally lead to the worship of those; but, in fact, they merely do not eat the plant or animal which is the shrine of their tutelary god. And though this is enforced by a tabu, the tabu is evidently distinct from the belief in the god's connection with the plant or animal; it is only the means of enforcing that belief—being the customary means used to prevent any act which would provoke a god to anger. The origin of tabu seems to be a vague fear of superhuman powers; this has become associated with certain things and acts; thus practically, tabu is a system of divinely appointed restraints—religion, in the primary sense of the word. The religious horror has attached itself—or, through the policy of priests and rulers, has become attached—to every prohibition supported by a strong expediency; which it is apt to do among rude peoples, especially where the prohibition relates to the family, or to the relation of tribesmen to their chief. It must have been through a long process of construction, carried on by the governing classes—the chiefs and the priests—that tabu became the system it now is. The extensive political application of tabu is sufficient evidence that the Polynesian chiefs have been adepts in the art of turning the religious feelings of their countrymen to their own account.

TACHOUT is the name given in Algiers by the Arabs to the small gall formed on the tamarisk tree, *tamariscus indica*. Since the discovery of photography these galls have become of considerable importance as a source of gallic acid, of which they contain a large proportion. The French chemists import considerable quantities; and the same gall, under the name of ma'ee, is imported for the same purpose by British chemists from India.

TACAMAHAG, or **TACAMAHACA**, a name which, from the number of its applications, has produced considerable confusion in the history of commercial products. No less than four different resins are known under this designation. One, from Mauritius, is obtained from a tree common in India and its islands, called the poon-wood tree, *calophyllum inophyllum*. Another, from South America and the West Indies, is obtained from *zanthoxylum (fagara) octandra*—this is usually called shell tacamahac. A third, also from South America, is yielded by a tree called *iceia tacamahaca*; it is supposed to be the Mexican copal. And the fourth is from North America, and is the produce of the Carolina or tacamahac poplar; it is collected in small quantities, and has only a small value for supposed medicinal properties. The others are chiefly used for varnishes.

TACCA, a genus of plants of a small natural order called *taccaceæ* nearly allied to *araceæ*. They are large perennials, with tuberous roots. The species are few, and are found in maritime places and woods in the South Sea islands and the warmest parts of Asia and Africa. Some of them (*T. pinnatifida*, etc.) are much cultivated for the sake of their tubers, which are used as an article of food, although they are acrid, and require maceration in water to remove their acidity, on account of which also they are generally eaten with vinegar, or some acid substance. They contain a large quantity of starch, which is wholesome and nutritious, and is imported into Britain as a substitute for West Indian arrow-root. It is known as *Tahiti arrow-root*. Dr. Seemann says that it is an effectual cure for dysentery, which other arrow-root is not. The boiled leaf stalks of the plants of this genus are also used in China and Cochin-China as an article of food.

TACHÉ, ALEXANDRE, b. Lower Canada, 1812; educated at St. Hyacinthe college, joined himself to the order of the Immaculate Conception, and in 1843 was ordained at the St. Boniface post of the Red River mission. From this point he traveled great distances toward the n.w. and in Manitoba. In 1853 he succeeded bishop Provencher, to whom he had previously been coadjutor, and in 1871 he became metropolitan. Archbishop Taché was the founder of the St. Boniface theological college, and has written books on the subject of his missionary labors in the north-west.

TACIT RELOCATION, in the law of Scotland, is a phrase borrowed from the Roman law, signifying that when a tenant continues in possession of the lands after his lease or term has ended, there is an implied or tacit renewal of the lease, whereby he continues bound to pay the same rent and observe the same stipulations. The same doctrine exists in English law, though the above phrase is not used.

TACITURNITY, in the law of Scotland, is a mode of extinguishing an obligation by mere silence, and making no claim upon it within a long time. It is a distinct ground, and embraces a shorter period than the ordinary prescription of limitation (q.v.); for if a creditor never apply for payment or performance of the obligation, a presumption arises either that there never was such an obligation, or that he has abandoned it. Much depends on the circumstances of each case whether such a doctrine is applicable; and, as a general rule, the periods of prescription are adopted as superseding the common law doctrine of taciturnity.

TACITUS, CAIUS CORNELIUS, the historian. Of his parentage, or of the time and place of his birth, we can only conjecture that his father was probably Cornelius Tacitus, a Roman eque, who is mentioned as a procurator in Gallia Belgica, and who died in 79. From the emperors Vespasian, Titus, and Domitian he received promotion and other marks of favor; and in 78 he married the daughter of Caius Julius Agricola. In 88, when Domitian was emperor and Tacitus prætor, he assisted as one of the quindecemviri at the celebration of the *Ludi seculares*. Agricola died in Rome in 83, while Tacitus and his wife were absent; and nothing further is known of the historian till 97, when, in the reign of Nerva, he was appointed consul suffectus, succeeding Tacitus Virginius Rufus, whose funeral oration he delivered. Tacitus had already attained distinction as an orator when the younger Pliny was entering upon public life; and both of them were appointed, in Nerva's reign in 99, to conduct the prosecution of Marius, then proconsul of Africa. Tacitus became one of the most intimate friends of Pliny, of whose letters 11 are addressed to him. The time of Tacitus's death is unknown, but he most probably survived Trajan, who died in 117. His extant works are: (1) *Vita Agricola*, written after the death of Domitian in 96, and universally admired as a masterpiece of noble sentiment and pregnant epigram. (2) *Historiæ*, written after Nerva's death in 98, and before the *Annales*, and embracing the period from the second consulship of Galba in 68 to the death of Domitian in 96. Only the first four books have reached us in a perfect state, but there must have been many more. (3) *Annales*, commencing with the death of Augustus in 14, and closing with the death of Nero in 68. These also have reached us only in an imperfect state. (4) *De Moribus et Populis Germaniæ*. This treatise is trustworthy only as regards those Germans who were best known to the Romans from their proximity to the Rhine. For the provinces beyond that river it has no value, whether geographical or political. (5) *Dialogus de Oratoribus*, if the work of Tacitus at all, must be his earliest. Tacitus is one of the greatest of historians. In love of truth and integrity of purpose he is equalled by few; in conciseness of phrase and power of saying much and implying more in one or two strokes of expression he is rivalled by none. The best editions are those of Orelli and Halm.

TACITUS, MARCUS CLAUDIUS, about 200–76, A. D.; b. Interamna (modern Terni), in Umbria; elected emperor after the death of Aurelian and an interregnum of seven months. He began his brief reign of 200 days at the advanced age of 75 years; one of the oldest and wealthiest of the senators. He instituted needful reforms in relation to the coinage and the morals of his subjects; being himself of temperate habit, upright, and honest; giving liberally to the state from his private fortune, and living as simply after his accession to the throne as in private life. He claimed descent from the historian Tacitus, whose works he ordered preserved with care in the public libraries, and copies made every year. He favored the restoration of the power of the senate. His victory over the Scythians is recorded on his coins by the inscription “Victoria Gotli” and “Victoria Pontica.” He died at Tyana, some say of a fever, others by assassination.

TACK, the Scottish law-term, synonymous with lease (q.v.).

TACK—TACKING. The *tack of a sail* is the lower windward corner. The *tack* is the rope employed in hauling down that corner to its proper position. The *tack of a fore-and-aft sail* is its lower forward clue or corner; it also designates the rope for hauling down that corner. A ship is said to be on the *starboard* or *port tack* when she is close-hauled, with the wind on the starboard or port side.

Tacking is the practice of beating up against an adverse wind by a zigzag course. If a vessel at A require to sail due n. to B, and if the wind be either n., or from any point n. of the line CAD, it is obvious that the wind will not carry her directly to her destination. As an extreme case, let the wind be n. or dead against her. By setting her sails obliquely, as at A, it will be possible to beat up in the direction AE. If the master consider that at E he has passed sufficiently from his straight course to B, he will then put his helm a-lee, which brings the ship's head straight to the wind, the tacks of the sails being at the same time set free. The after-sails are then smartly braced over to the opposite side, and the ship's head falls off from the wind in an opposite direction to that previously held, until the course is EF. This process is repeated on each side of the line AB, until at length the ship makes her port, B. The length of each tack, as EF, is called a *board*. When the wind is straight ahead, as in the above example, the several boards should obviously be equally on each side of the line AB. If, however, the wind were not so direct, it would be necessary that the boards in one direction should be shorter than those in the other. Sometimes, from the nature of the channel, as an estuary, etc., it is necessary to take a long tack one way, say to starboard, and a very short one to port. This is known as “sailing with a long and a short leg.”

TACKING OF MORTGAGES, in the law of England, is a practice that sometimes occurs in the course of mortgage securities, when one person acquires more than one mortgage over the same estate. Thus, though mortgages, according to the general rule, rank according to the order of date, yet, if a third mortgagee, who became so without notice of a second incumbrance, purchase the first mortgage even after notice of the second mortgage, so as to require a legal title, and if he holds them both in his own right, he can tack the one to the other, and so obtain priority for the third mortgage over the second mortgage. This is on account of an old technicality, scarcely intelligible to other than lawyers.

TACONIC MOUNTAINS, in the co. of Berkshire, w. Mass., and the co. of Bennington, Vt.; running n. and s. on the e. boundary of New York, uniting the Green mountains of w. Massachusetts with the Highlands of the Hudson. They were named from the characteristic strata of the range, a kind of rock (believed to be older than the Silurian system) to which prof. Emmons gave the name of taconic; attaining a thickness of 30,000 ft. along the Appalachian chain. The formation in various portions consists of slates, sandstones, quartzites, limestones, and iron ore. The highest peak in Vermont is mount Equinox, 2 m. w. of Manchester, 3,872 ft. above the sea; in Massachusetts, mount Greylock, near North Adams, 3,505 ft. in altitude, is the highest elevation in the state.

TACONIC SYSTEM, an extensive series of rocks in the United States, described by Dr. Emmons. They consist of two divisions, the upper having a thickness of 25,000 ft., and containing lower Silurian fossils; and the lower, with 5,000 ft. of thickness, in which, as yet, no fossils have been found, but which is generally considered to be the equivalent of the Cambrian rocks of Britain.

TACTICS, MILITARY. Strategy (q.v.) is the art of maneuvering armies with reference to the objects of the whole campaign—the securing of communications, the cutting off an enemy from his base, throwing him into a position where he must fight at a disadvantage, or surrender, etc. Tactics has regard to the evolutions of an army in the actual presence of an enemy. It is the strategy of the battle field; the science of maneuvering and combining those military units which drill, discipline, and the regimental system have brought to the perfection of machines. It was admirably described by Napoleon as *the art of being the stronger*—that is, of bringing an overwhelming force to bear on any given point, whatever may be the relative strength of the entire armies opposed.

The earliest records of battles are those of mere single combats, in which the chiefs, fighting either on foot or in chariots, performed great deeds; and the commonalty, who apparently were without discipline, were held in profound contempt. With the growth of democracy arose the organization of the phalanx (q.v.), the advance of which was irresistible; and its firmness equally so, if charged in front. It, however, changed front with great difficulty; was much deranged by broken ground; and failed entirely in a pursuit, or if attacked in flank. Far lighter, and more mobile, was the Roman legion (q.v.). Among Roman tactics was also the admirable intrenchment, which they scarcely ever omitted as an additional source of strength for their position.

“Events reproduce themselves in cycles;” and with the decay of Roman civilization came again the mail-clad heroes and cavaliers—mounted this time on horses—who monopolized the honors of battle, while the undisciplined footmen had an undue share of the dangers. Later in the feudal period, this disparity between knight and footmen was diminished by the employment of bodies of archers, whose shafts carried distant death. The adoption of gunpowder for small-arms altogether neutralized the superiority of the armored knight. This change brought infantry into the front place in battle, and threw cavalry into the status of an auxiliary. The French revolutionary wars tended much to the development of artillery as a field-weapon, and Napoleon employed this terrible engine to its fullest extent, a practice followed by the best modern generals, who never risk a man where a cannon-ball can do the work. Frederick the great was considered an innovator for fighting with infantry four deep. During the French war, the formation of three deep became general, and still obtains in several European armies. Before the battle of Waterloo, the British leaders had acquired sufficient confidence in their troops to marshal them in a double line. It is doubtful whether the advance in arms of precision will not soon necessitate the formation in a single line, or even in a single line in open order.

It is impossible, in an elementary article of this character, to give even an approach to an essay on modern tactics, which is an intricate science. We can only notice briefly a few of the more important principles.

First, as to the art of being the stronger, which is undoubtedly the highest recommendation in a general, we may cite the example of the battle of Rivoli. In 1796, Napoleon was besieging Mantua with a small force, while a very much smaller army operated as an army of observation. The Austrian commander had collected at Trent a force powerful enough to crush completely the French army, with which he was marching south. Parallel with his course lay the lake of Garda, and to prevent the enemy escaping up one side, as he marched down the other, the Austrian leader divided his army into two powerful corps, and marched one down each side of the lake. The

instant the young French gen. knew of this division, he abandoned the siege of Mantua, collected every available man, and marched against one body of the enemy. Though far inferior on the whole, he was thus superior at the point of attack, and the victory of Rivoli decided virtually the whole campaign. This corresponded in principle with Napoleon's general plan in battle. He formed his attack into column, tried to break through the center of the enemy's line; and if he succeeded, then doubled back to one side, so as to concentrate the whole of his own force against one half of the enemy's, which was usually routed before the other half of the line could come up to the rescue.

Taken collectively the tactics of the three arms may be thus summarized: The infantry form the line of battle, and probably decide the day by a general advance over the enemy's ground. The cavalry seek to break the opposing infantry by frequent charges in front, or on any flank which may be left exposed. If a part of the line wavers, a charge of horse should complete the disarray. When the rout commences the cavalry should turn it by furious onslaught into utter discomfiture. The province of the artillery is to canonade any portion of the line where men are massed, or where a charge is about to be made; to demoralize cavalry, and generally to carry destruction wherever it can best disconcert the enemy.

Adverting now very briefly to the tactics of the several arms individually, we have—

Infantry.—This force has four formations—skirmishers, line, column, and square. The skirmishers precede and flank an advancing line or column, picking off the enemy, whose masses offer good mark, while their own extended order gives them comparative impunity. If resistance be encountered in force, the skirmishers retreat behind their massed supports. The line is a double or treble line of men, firing or charging. For musketry purposes it is the most formidable formation, and is the favorite British tactic in every case where the officers can depend on the steadiness of their men. For bursting through a line the deep column is the most effective. It is the favorite French formation, and during the revolutionary and Napoleonic wars, the British and Russians alone succeeded in resisting it. At Vimiera the 50th regiment, 700 strong, stood in line: it was attacked by a column of 2,000 French. The English col. threw back his left (which was the end attacked), and advanced his right, delivered a volley at point-blank range, charged the column in flank, and utterly routed it before the French could deploy into line to resist the onslaught. The column is, therefore, the best formation on a march; the line, when in actual collision with the enemy. The formation in Echelon (q.v.) to a great extent combines these advantages. See SQUARE.

Cavalry.—The function of heavy cavalry is limited to the charge in line. The light cavalry form in small sections, to scour the country, collect supplies, and cut off stragglers.

Artillery.—No distinct tactics exist for this arm beyond the fact that a concentrated fire is vastly the most effective, and that the artillery should always have a support of infantry at hand, to protect it from a sudden incursion of hostile cavalry.

Tactics of position depend on the moral energy of the commander-in-chief. Few would dare, as Cæsar did, an invasion in which there was no retreat, if defeated. It is a military maxim not to fight with the rear on a river, unless many bridges be provided for retreat, in case of disaster. A convex front is better than a concave front, because internal communication is more easy. The flank should be protected by cavalry, or preferably by natural obstacles. In battle a long march from one position to another, which exposes the flank to the enemy, is a fatal error. By such the French won Austerlitz, and lost Talavera. In a pursuit a parallel line is better than the immediate route the retreating enemy has taken, as supplies will be more readily procured, and he may by celerity be attacked in flank. This was strikingly exemplified in the Russian pursuit of Napoleon's army retreating from Moscow.

TACTICS, NAVAL. With the advent of steam, iron-plated ships, and rams, the tactics under which Rodney and Nelson fought and conquered have passed away, while the principles of the new warfare have scarcely been sufficiently established for reduction to theory. A glance at the obsolete tactics of bygone times must, therefore, suffice in the present article.

In ancient naval engagements, where the vessels fought on the comparatively smooth waters of the Mediterranean, and where the use of oars rendered the commanders nearly independent of the wind, the attack consisted of a charge with the beaked prows, followed, if that failed, by the use of balistæ and a hand-to-hand struggle. See NAVIES, ANCIENT. The introduction of gunpowder, with broadside ordnance, necessitated a change, and the great desideratum of each admiral was to present as long a line of broadsides as possible to the enemy, to take care that none of his ships was masked by the intervention of another between it and the foe, and to endeavor in each ship to oppose its broadside to the bow or stern of a hostile ship, so as to obtain the preponderance of force, and to rake his decks. The ships of two decks and upward formed the line of battle, while frigates and smaller vessels served as look-outs and skirmishers. A fleet in one line would, however, have been of inconvenient length for sailing, and it was usual to sail in three, six, or nine parallel lines while traversing the ocean, the ships of the rear lines tacking into their places in the line of battle on the signal to form for

action. The great principle of maneuvering was to get the weather-gage, i.e., to be to windward of the enemy, both for facility of navigation, and because the smoke would inconvenience him most. The standing attempt during the French war was to double the enemy's line (see CLERK, JOHN, of Eldin) by piercing it, or passing it at the van or rear, and then, by tacking in its rear, to place his ships between two fires. This was first practiced in lord Rodney's action of 1782, and was successfully repeated by Nelson at the battle of the Nile. Under steam, and with ships carrying colossal ordnance, naval tactics have entirely changed. It used to be the object to avoid being raked; it is now to avoid being hit at all. The projectiles used are so tremendous that a few hits involve destruction. Ships are consequently constructed so as to offer the least mark to ordnance; and with the same view they are kept constantly in rapid motion. Actions are fought, not, as in old time, within pistol-shot, but at a mile or two miles' distance. The loss of life is less; for the battle is no longer decided hand-to-hand by the cutlass and the boarding-pike, following a furious cannonade; but after a few long shots with ponderous missiles, one or other vessel becomes disabled, and being helpless, yields the victory to her foe. The ships will be steamed end on if they act as rams, and also to offer less mark to shot. Rival fleets have never yet met on a large scale to fight under the conditions of modern war.

TADEMA, LAWRENCE ALMA, a distinguished painter, b. Jan. 8, 1836, at Dronryp in the Netherlands. He was educated at Antwerp, but early settled in London, where he was naturalized as an English subject in 1873. His numerous and very popular paintings deal chiefly with antique classical and Egyptian subjects, which, under Tadema's handling, have a very vivid air of reality. "How they amused themselves in Egypt 3,000 years ago" (1863) is one of Tadema's earlier paintings; "A Sculptor's Model" (1878), one of his last. Tadema is an A.R.A., and a member of various foreign academies; he is a chevalier of the legion of honor, and a knight of several orders.

TADMOE. See PALMYRA.

TADPOLE. See FROG.

TAEI, a money of account in China, is equivalent to about 6s. 8d. sterling, or to a thousand of their sole coin, the "tsên," tchen, or "cash."

TENIA AND **TENIADÆ**. See TAPEWORM.

TAE-PINGS, the name given to the Chinese rebels who made their appearance in 1850, and (see CHINESE EMPIRE) desolated some of the best cultivated provinces of China. After the war of 1860 it became the interest of the English, French, and American governments to re-establish order in China. The repulse of the rebels at Shanghai in Aug., 1860 had been followed by several engagements between them and the imperialists, in which the Tae-pings were defeated, mainly in consequence of the re-organization of the imperial army by Ward, an American. In the beginning of 1862 the Tae-pings again advanced on Shanghai, and were twice defeated. In that year Ward was killed; and "Ward's force," handed over to an English officer, took the name of Gordon's brigade. Permission was also granted to capt. Sherard Osborne to organize in England a small fleet of gun-boats, to ascend the Chinese rivers and re-establish order. Gordon's brigade rendered essential service to the imperial government. The rebels were defeated in upward of 16 engagements; and in 1864 almost every important city was taken from them. Capt. Sherard Osborne's expedition was less successful. He found that the jealousy of Chinese officials would not permit him to take the steps necessary to discharge properly the duty he had undertaken, and he therefore threw up his commission, and returned to England. The conduct of the imperial authorities at Su-chow, where a horrible massacre took place, led to the withdrawal of the English military force; but the rebellion had been effectually checked. They were finally dispersed in April, 1865, when they were routed by the imperial army at Kia-ying-chou in Kwantung. In the same year, the Nienfei, or marauders of the north, began to be troublesome. This was a marauding expedition, without political significance, organized by restless spirits among farmers who had been ruined by the overflowing of the Yellow river, the repair of the embankments of which had been neglected on account of the confusion and expense of the Tae-ping rebellion. The last show of active warfare made by a body of Nienfei was in the beginning of 1866, when, joined by some imperialist regiments whose pay was in arrear, they threatened Hankow; and would have attacked the European settlement but for the arrival of some English gun-boats. The malcontent imperialists were easily brought back to allegiance, and the marauders were dispersed, and have not been authentically heard of since.

The Mohammedans of the n.w. of China give the imperial government trouble from time to time. Their risings are often on political grounds, and they are on this account apt to be confounded with the annihilated Tae-pings. See PANTHAYS.

TAFFETA (or Taffeta), a term of somewhat general application in silk-mercery. It was formerly applied to all plain silks simply woven by regular alternations of the warp and weft, and is by some writers supposed to be the first kind of silk-weaving known even to the Chinese, from whom it came to us. Modifications have, however, been introduced, by varying the quality of the warp and weft, and by the substitution of various colors for the single one of the original taffeta. It has therefore become a sort of

generic term for *plain silk*, gros de Naples, gros des Indes, shot or chameleon silk, glacé, and many others, and even for some combinations of silk, wool, and other materials.

TAFFRAIL, in a ship, is the rail over the heads of the stern-timbers, extending across the stern from one quarter-stanchion to another.

TA FIA, a name used in the sugar-producing colonies for a kind of rum distilled from molasses. The term is only in general use in French colonies.

TAFILET', (or Tafiilet), one of the four territorial divisions of Morocco (q.v.).

TAGANROG', an important sea-port of Russia, in the gov. of Et katerinoslav, on the n. shore of the sea of Azov, 20 m. n.w. of the chief mouth of the Don. It was founded by Peter the great in 1696, was lost to Russia from 1712 till 1774, when it again reverted to the people who founded it, and since that time it has increased in importance yearly. The port of Taganrog is so shallow that large ships cannot approach within half a mile of the quay, and at this distance from shore they load and unload by the help of barges. The harbor is wholly unprotected. Owing to its position on the shore of a very fertile country, it is able to export wheat in large quantities (1,050,156 quarters being exported in 1872), as well as linseed, hempseed, skins, wool, butter, iron, copper, and Russian leather. Of these articles, the last four are obtained from the governments of Perm and Orenburg, and are exported chiefly to Turkey, Greece, and Italy. In 1864, 1664 vessels, of upward of 350,000 tons, entered and cleared the port; and the exports for 1873 amounted to 28,797,839 roubles, or about £4,560,000; the imports chiefly wine, agricultural implements, and machinery, tea, fruits, and porter, amounted to 8,048,663 roubles, or about £1,273,500. Pop. '67, 25,027.

TAGLIONI, MARIE, a celebrated *danseuse*, b. at Stockholm, April 23, 1809, of Italian parents, her father (Filippo Taglioni, b. at Milan, 1777) having been successively ballet-master at several opera-houses in different parts of the continent. Mlle. Taglioni made her *début* in Paris in 1827, where she created a perfect *furor*, and was at once recognized as the first of ballet-dancers. Her success was equally great at most of the other European capitals, London included. She retired from the stage in 1847, and after ward resided in Italy and in London, where she taught dancing and deportment.

TAGUS (Span. *Tajo*), the largest river of the Spanish peninsula, rises on the frontier of New Castile and Aragon, between the Sierra de Albarracín and the Sierra de Molina, about 45 m. n.e. of the city of Cuenca. It first flows n.w. for about 30 m. to its union with the Gallo, at which point it curves to the s.w., and flows in that direction to Toledo, whence it flows w. to Abrantes in Portugal. From Abrantes the river flows s.w., and passing Lisbon, enters the Atlantic about 10 m. lower down. At Peralejos, a few m. from its source, it is 1 ft. deep, 15 paces broad, and confined between rocky walls 400 ft. high. At the city of Toledo, it breaks through a romantic rocky pass, the walls of which are upward of 200 ft. high. From Villavellia, 18 m. within the Portuguese border, the Tagus is navigable to its mouth, a distance of 115 miles. Above Lisbon, the river widens like an estuary, being in some places 5 m. broad; opposite Lisbon, however, it is only 1 m. broad. The principal affluents are the Jarama, Guadarrama, Alberche, Alagon, and Zezere from the n. and the Guadiela and Rio del Monte from the south. Total length, 540 miles.

TAHI TI, or OTAHEITE, the chief of the Society islands (q.v.), is 32 m. long, about 120 m. in circumference, and consists of two peninsulas, connected by an isthmus about 3 m. broad, but which is submerged at high water. Pop. 13,800, of whom more than 13,000 are natives. The chief town is Papiete, with a safe harbor, a patent slip for vessels of 400 tons, and careening quays. For the trade, history, etc. of Tahiti, see SOCIETY ISLANDS.

TAH'LEQUAH, a t. and capital of the Cherokee nation, Indian territory, lying in the valley of the Illinois river, 12 or 15 m. e. of the Missouri, Kansas and Texas railroad. Pop. estimated at 3,000. The civilization of the Indian residents is high, and the place is of great interest as showing what may be done in the education of our aborigines. The t. has schools and a church, a newspaper, printed in both the Cherokee and English tongues, and a capitol erected at a cost of \$20,000.

TAIKO SAMA (the name by which Hidéyoshi Toyotomi is best known to English speaking people); 1536-98; b. in the province of Owari, Japan, of humble parents; when still a boy became a retainer of Nobunaga, and rose to be a general of commanding military genius. He avenged the murder of Nobunaga, humbled Satsuma, and reduced the warring clans to submission. Having tranquilized the native empire, he found employment for his restless armies in invading Corea in 1592. He sent Konishi and Kato into the peninsula with 80,000 men, who in a few weeks entered the capital, overran the eight provinces, and met and defeated the hosts of the Chinese sent to succor the Coreans. Having been in 1586 made regent, he retired in favor of his son in 1591, and hence took the title of taiko (*samur* meaning lord, or sir). He greatly patronized art, stimulated by personal favor the porcelain manufacture, and many other industries, encouraged commerce, and internal national improvement. Compelled to act with a high hand between the rival sects of the Jesuits and Dominicans, and to regulate the foreign relations of Japan, he shipped the European friars from the country, and when they re-

turned, had them hanged. The "age of Taiko" is looked upon with admiration by the Japanese, and his life has been many times written in well-illustrated books, his adventures being standard subjects of Japanese decorative art. His last words, like those of Napoleon, were an order to his troops. On his death the victorious soldiers were recalled from Corea. His successor, Iyeyasu, whose genius gave peace to the empire for over 260 years, followed in the main the policy of Taiko.

TAIL, ESTATE, is, in English law, an estate given to A and the heirs of his body, or A and the heirs-male of his body, or some other class of heirs less extensive than the class of heirs-at-law. It was anciently a question whether in such a case A, the father, could defeat the right of the children, and break the entail. In England, it was early decided that A could, by a sham process, called a fine or recovery (q.v.) break the entail; while in Scotland it was otherwise, at least since 1685, the Scotch legislature having legalized a mode of securing the entail, and preventing A, or any of his successors, from breaking it. See **ENTAIL**.

TAILOR-BIRD, *Orthotomus*, a genus of birds of the family *sylviade* (q.v.), with a long graduated tail, the feathers of which are narrow. The species are numerous, natives of the East Indies and of the Indian Archipelago, and haunt cultivated grounds, where they are commonly seen in pairs. Their flight is rapid and undulating, and they seldom ascend above the lower branches of trees. The name *tailor-bird* is derived from the way in which the nest is formed. Two leaves are taken at the extremity of a twig, and are sewed together by their edges, or a large leaf is sewed together; the necessary holes being made by the bill, and vegetable fibers forming the thread. Within the hollow thus made, a quantity of a cottony substance is placed to receive the eggs.

TAILZIE, the ancient term in the law of Scotland to denote a deed creating an entailed estate. See **ENTAIL**.

TAIN, a royal, parliamentary, and municipal burgh in the county of Ross and Cromarty, on the south shore of the Dornoch firth, and 24 miles n.e. of Inverness. There is no proper harbor. The most interesting building is a small ruined chapel, remarkably rude and simple in architecture, and said to date from the 13th c.; and there is also a collegiate church, founded in 1471, and an endowed academy incorporated by royal charter. Brewing and iron-founding are carried on. Pop. of royal burgh (1871) 2,287.

TAINÉ, HIPPOLYTE ADOLPHE, a French critic, was born at Vouziers in Ardennes, April 21, 1828, and studied at Paris, where in 1853 he obtained the diploma of *docteur ès lettres*, for two essays, *De Personi Platonici*, and *Essai sur les Fables de Lafontaine*. They were followed by his *Essai sur Tite Live* (1854), crowned by the French academy; *Les Philosophes Français du dix-neuvième Siècle* (Paris, 1856); *Essai de Critique et d'Histoire* (Paris, 1857); *Histoire de la Littérature Anglaise* (Paris, 1864); *Philosophie de l'Art* (1865; Eng. transl.); *Notes sur l'Angleterre* (1871; Eng. transl.); and others. In the *Littérature Anglaise* (Eng. transl., Edinburgh, 1872), the author surveys and criticises our whole literature from a point of view which is conceived to be rigorously scientific. According to Taine, there are three things to be borne in mind when writing the history of a nation's literature: first, the *race* to which the nation belongs; second, its *position* both geographical and in civilization in the different phases of its literary development; and third, the *period* or duration of these. Under this view, the history of literature assumes the character of a psychological problem. Among Taine's recent works is *Les Origines de la France Contemporaine*, of which the first installment, *L'Ancien Régime*, appeared in 1875 (Eng. transl., 1876). In this the writer gives a graphic account of the social disease that led to the French revolution. A picture of the revolutionary age itself followed in *La Révolution* (vol. i, 1878). The new régime is afterward to be described. Taine was elected a member of the academy in 1878.

TAIRA, or **HEI**, the name of a celebrated family of Japanese nobles, who with their rivals, the Minamots, kept the empire in turmoil during two centuries. Like the wars of the Roses in England, the war of the red and white banners in Japan ended only when one family was almost annihilated. The Taira house was founded by Takamochi, a great-grandson of the mikado Kuammu who reigned, 782-805. His descendants were for two centuries the military vassals of the emperor. Kiyomori, who became premier, 1167, was virtually ruler of Japan, his daughter being empress, his grandson mikado, and 60 of his relatives holding the highest offices at court, and their lands covering thirty provinces. At the height of their power, the long feud with their rivals, the Minamots, broke out in implacable enmity, 1156. In 1184, after suffering the loss of several bloody battles, driven from Kioto, and from castle to castle, they were slain or imprisoned to the last man, except a few exiles, as the result of the great naval battle of Shimonoséki, and the young mikado Antoku was drowned. In 1870, after 700 years of seclusion, the remnant of the Taira exiles were discovered in a remote mountainous district in Higo, island of Kiushiu. They number 500 souls, and subsist by hunting.

TAIT, ARCHIBALD CAMPBELL, D.D., LL.D.; b. Edinburgh, 1811; educated at the university of Edinburgh and Oxford, becoming afterward a public examiner of the latter; succeeded Dr. Arnold as head-master of Rugby, 1842-50; was made dean of Carlisle, 1850; bishop of London, 1856; archbishop of Canterbury, 1868. He is known as a

prominent opponent of the Tractarians or Puseyites. He has published *The Dangers and Safeguards of Modern Theology*; *The Word of God and the Ground of Faith*; and a volume of sermons.

TAIT, PETER GUTHRIE, b. England, 1825; graduate of Cambridge, fellow of St. Peter's college; prof. of mathematics in Queen's college, Belfast; prof. of natural philosophy in the university of Edinburgh, 1862. Associated with W. J. Steele he published *A Treatise on Dynamics of a Particle* (1856); *Elementary Treatise on Natural Philosophy*, with sir Wm. Thomson, fellow of St. Peter's college (1867). He has been associated with prof. Balfour Stewart in some publications. He published *Thermodynamics* (1868).

TAI-YUAN, a city of China, in the province of Shan-si, on the Fuen-ho, an affluent of the Hoang-ho, 250 m. s.w. of Peking. It is said to be about ten miles in circumference, fortified and populous. Porcelain, iron wares, and carpets are manufactured.

TAI-WAN-FOO, the capital of the island of Formosa (q.v.), on a large plain 3 m. from the s.w. coast, with a pop. of 120,000. It is a large straggling town, contains many park-like spaces with fine trees and green lanes, and is surrounded by a high battlemented wall, six miles in extent. Its chief edifices are the residences of the mandarins, and the temples. The harbor of Tai-wan-foo, at Amping, is only a shallow open roadstead; trade is carried on only in five months of the year, cargo having to be carried in native boats. The chief export is sugar, which is grown all over the plain of Formosa; also rattan canes. About 27 m. to the s. is the harbor of Takao, the headquarters of the customs staff; it is better than that of Amping. See a "Description of Formosa" in the *Geographical Magazine* of 1877.

TALAVEIRA DE LA REYNA, a t. of Spain, in New Castile, in the modern province of Toledo, is charmingly situated on the Tagus, 75 m. s.w. of Madrid. It is ancient, straggling, dirty, and inconvenient, is surrounded by interesting old walls, and abounds in antique picturesque fragments. It was formerly a flourishing town; but of its manufactures, only that of silk is now carried on. Fruits are extensively produced in the vicinity. Here, on July 27 and 28, 1809, sir Arthur Wellesley, with 19,000 English and German troops, and about 34,000 Spaniards, who, however, with very trifling exceptions, were not engaged, defeated upward of 50,000 veteran French troops, under Joseph Bonaparte and marshals Jourdan and Victor. — Pop. 7,000.

TALBOT, perhaps originally a name equivalent to blood-hound (q.v.), but afterward applied to a race of hounds, now extinct, or nearly so, which seem to have been kept for show rather than for use. The talbot was of pure white color, with large head, very broad muzzle, long pendulous ears, and rough-hair on the belly. The white St. Hubert dog was either the talbot or a nearly allied breed. The talbot is the badge of the ancient house of Shrewsbury (surname Talbot), and the crest of some of the princely houses of Germany.

TALBOT, a co. in w. Georgia, having the Flint river for its n.e. boundary; drained by Upatoi creek; 350 sq.m.; pop. '80, 14,115—14,102 of American birth, 9,667 colored. It is intersected in the s. by the South-eastern railroad. The surface is hilly with a large proportion woodland. The soil produces grain and sweet potatoes, and is susceptible of much higher cultivation. Live stock is raised. It has grist mills and cotton gin works. Co. seat, Talbotton.

TALBOT, a co. in e. Maryland, having the Chesapeake bay on the w., the Choptank river on the s. and s.e.; drained also by Tuckahoe creek; 250 sq.m.; pop. '80, 19,065—18,759 of American birth, 7,327 colored. It is intersected by the Delaware and Chesapeake Bay railroad. It includes Poplar and Tilghman's islands, and the w. portion is nearly separated from the main-land by a navigable inlet. The surface is level and divided in nearly equal proportions into forests and plain. The soil produces large crops of grain, and live stock is raised. Manufactures of lumber, iron, carriages, and wagons, clothing and shipping are the principal industries. It has an important trade in oysters. Co. seat, Easton.

TALBOT, JAMES, LL.D., Baron Talbot de Malahide, b. Ireland, 1805; educated at Trinity college, Cambridge; member of parliament for Athlone in the liberal interest, 1832, defeated in 1835. He succeeded to his father's title in 1850; was created peer of the United Kingdom, 1856. He is president of the archaeological society of Great Britain and Ireland. He occupies a similar position in relation to the geological and zoological societies of Dublin; and resigned the office of president of the council of the royal Irish academy, 1869. He is the author of a monograph of the house of Talbot, including the senior branch, the head of which is the earl of Shrewsbury.

TALBOT, JOHN, was rector of Fretherne, England; chaplain of the centurion in which the missionaries of the Gospel propagation society came to America, 1702; founder and first rector of St. Mary's church, Burlington, N. J., 1703; for many years a leader of the church of England in the American colonies; consecrated bishop by non-jurors in England, 1722.

TALBOT, MATTHEW, b. England in the middle of the 18th century. He published *An Analysis of the Holy Bible, containing the whole of the Old and New Testaments*

collected and arranged systematically in 30 Books, which are subdivided into 285 Chapters and 4,144 Sections. This was republished in the United States by the rev. Dr. Nathaniel West, which was revised under the title of *The New and Complete Analysis of the Holy Bible* by the Rev. R. D. Hitchcock.

TALBOT, SILAS, 1750-1813; b. R. I.; present at the siege of Boston during the revolutionary war as capt. in a regt. from his state; brev. maj. by congress, 1776, for skillful work in New York harbor against the British fleet. He was wounded at fort Mifflin, 1777, but remained on the field till the fight was over. In the following year he assisted gen. Sullivan by transporting the American forces from the main-land to Rhode Island; brevet lieut. col. for the brilliant exploit of capturing the British floating battery *Picot*, 22 guns, anchored in one of the channels threatening Newport. In 1779 on a cruise off the New England coast, with his prize and the sloop *Argo*, 10 guns, he captured *The Lively*, 12 guns, and 2 letters-of-marque, *The King George*, and *The Dragon*; was made brevet capt. in the navy, 1779, for taking *The Dragon* after a four hours' battle. He was taken in 1780 by the British and imprisoned in the Jersey prison; exchanged the following year. At the close of the war he bought the confiscated property of Sir William Johnson near the Mohawk river; was representative to the assembly for several years; member of congress, 1793-94. The frigate *Constitution* (Old Ironsides) was built under his supervision, and in 1799 was his flag-ship during a cruise in the West Indies. He resigned 1801, and passed the rest of his life in New York.

TALBOT, WILLIAM HENRY FOX, celebrated in connection with photography, was the son of William D. Talbot of Locock Abbey, Wilts., and was b. in 1800. He was educated at Harrow, and afterward at Trinity college, Cambridge, where he took his degree with honors, and obtained the junior chancellor's medal in 1821. In the first parliament summoned after the passing of the reform bill, Talbot sat for Clippenham; but scientific investigation being more to his taste, he gave up politics, and devoted himself to the problem of fixing shadows, ignorant at the time of what had been effected in this department by Wedgwood and Davy. Step by step he discovered for himself a method of obtaining and fixing sun-pictures, and on the dissemination of a report as to Daguerre's successes in the same field, secured his just rights by publishing a paper (*Phil. Mag.*, Mar., 1839), in which the successive steps of his investigation and their result were detailed. See PHOTOGRAPHY. This process, by which a negative (q.v.) was primarily obtained, was subsequently improved by his invention (patent dated Feb. 8, 1841) of the calotype (q.v.) process. Soon afterward he obtained fresh patents, for an "instantaneous process" (which seems to have well deserved the name, as by it a legible picture was obtained of a printed bill fastened to the rim of a wheel revolving 200 times per second), a mode of "photographic engraving," and a "polyglyptic process." A later invention of his, patented in 1858, was called by him photoglyphic engraving; see the art. PHOTOGRAPHIC ENGRAVING. In 1842, Talbot obtained the medal of the royal society for his previous discoveries. Latterly he devoted himself to the study of general physics, and to philological and miscellaneous researches. He died Sept. 17, 1877. Among his works are *Hermes, or Classical and Antiquarian Researches; Legendary Tales; Illustrations of the Antiquity of the Book of Genesis*; and a work on *English Etymologies*.

TALBOTYPE, a photographic process, called by the inventor, Mr. Fox Talbot, the calotype process (q.v.). Its essential features consist in the production in the camera of an image by light on the surface of chemically prepared paper, and this distinguishes it from other paper processes, and by consequence from other photographic processes.

TALC, a mineral allied to mica (q.v.), and, like it, easily separated into very thin flakes, which are transparent and flexible, but not elastic, like those of mica. Talc is composed almost entirely of silica and magnesia, in the proportions of 57-63 silica, and 30-35 magnesia, with 2-6 water. Its colors are silvery white, greenish white, and green. It has a pearly or semi-metallic luster, and is unctuous to the touch, in which it differs from mica. It occurs crystallized, generally in hexagonal tables, or in long prisms: the primary form is a rhomboid. It is also found massive, in beds chiefly in micaceous schists, gneiss, and serpentine.—A kind called *indurated talc*, or *talc slate*, has a curved slaty structure, and is not separable into laminae, like common talc. It approaches in character to stentite, and is used for similar purposes.

TALCA, a t. in Chili, in the province of Talca, of which it is the capital; pop. about 18,000. It is on the Maule river, about 45 m. n. of Chillan; contains a seminary for priests, and other educational institutions, and has a growing trade.

TALCOTT, ANDREW, b. Conn., about 1798; graduate of West Point, 1818. In 1819 he accompanied gen. Atkinson on an expedition to the upper Missouri and Yellowstone rivers to establish military posts; returned to the c. and in 1821-35 engaged in building defenses at Hampton Roads, fort Delaware, and other exposed situations. In 1832-36 he was engaged on the boundary line between Ohio and Michigan, and the improvements on the Hudson river; resigned 1836 and became division engineer on the Erie railroad. He has been on many important commissions for constructing dry-docks and defenses, and has been chief engineer of several railroads.

TALCOTT, JOHN, about 1625-88; b. England; brought to Massachusetts by his father who became one of the governor's "assistants." The son held the office of treas-

urer of the colony, and is best known as the leader of the expedition which saved Hadley from the attack of 700 Indians, and for his courage in other Indian warfare.

TALEGALLA, a genus of gallinaceous birds, of the family *megapodidae*, having a strong, thick, and very short bill, the upper mandible curved and pointed; the head and neck almost quite naked; the wings short and round; the tail rather long, rounded on the sides; the legs strong, feathered a little below the joint of the tibia and tarsus; the tarsi covered with scales in front; the toes long and strong; the claws large and sharp. The species are natives of Australia and New Guinea. The best known is the BRUSH TURKEY (*T. lathami*) of Australia, also known as the WATTLED TALEGALLA and the NEW HOLLAND VULTURE, the latter name being given to it on account of its naked head and neck, covered in part with fleshy wattles. It is pretty common in New South Wales, inhabiting the most thickly wooded parts. It is a large bird, about the size of a turkey, with blackish-brown plumage. It is shy, and when pursued, endeavors to escape by running through the thickest brush, or by leaping to the lowest branches of a tree, from which it ascends higher and higher, branch by branch. It thus avoids the dingoes or native dogs, which, however, often hunt it down on open ground. It is easy game to the sportsman, who finds it roosting under shelter of the branches of trees during the heat of the day, and although several of a flock are shot, the rest keep their place undisturbed. The talegalla is generally seen in small flocks, and they make their nests together, the males heaping up, by means of their feet, mounds of several cartloads of earth and decayed leaves, which are used from year to year, new materials being added every year. The eggs are hatched by the heat of the sun and of the fermenting mound, each egg being separately buried. The parent birds partially uncover them during the day. Nearly a bushel of eggs may sometimes be found in a single heap. The male bird pays great attention to the young after they are hatched, covering them up partially in the mound at night for warmth. The flesh of the talegalla is excellent, and the eggs are also very delicate and eagerly sought after. It is thought that this bird might easily be added to the list of our domestic poultry.

TALENT (Gr. *talanton*, from a root to balance or weigh), a word used by Homer to signify indifferently a balance, and a definite weight of some monetary currency. But the weight of money to which Homer applies the term talent was very different from that to which it was applied in later times. Tradition assigns to Pheidon, king of Argos, the introduction of the talent as a standard of money and weight. The exact identity of the Æginetan talent with that known as the Babylonian, and generally employed in the east, points to its true origin. It was in all probability introduced into Greece by the Phœnicians, who also introduced a smaller monetary measure and weight, which was by the Greeks known as the Euboic talent. The names Æginetan and Euboic indicate that the talents to which these epithets apply were first used in Ægina and Eubœa; and though, in the east, the larger talent was used for silver, and the smaller for gold, after their introduction into Greece all such distinctive application was soon done away with. The use of the Euboic talent was mostly confined to Athens, Chalcis, and the Chalcidian colonies; while the Æginetan prevailed over the rest of the Greek world. In the 6th c. B.C., Solon introduced at Athens a new talent, which, as the *Attic talent*, succeeded, partly through its superior purity, and partly on account of the greater commercial activity of Athens, in supplanting the other two standards. These several talents were similarly subdivided into 60 minæ, the mina into 100 drachmæ, and the drachma into 6 oboli; and their relative proportions are Æginetan talent: Euboic talent: Attic talent:: 30: 25: 18, both with respect to their values as weights, and as measures of monetary amount. The following are the values as compared with English standards:

	AS WEIGHT.		AS MONEY (SILVER).		
	lbs.	avoirdupois,	£	s.	d.
Æginetan talent	=	95.	=	406	5 0
Euboic "	=	79.16	=	338	10 10
Attic "	=	57.	=	243	15 0

But by the same decree of Solon, a new commercial talent, of increased weight, was introduced, but only as a weight for goods, not for money.

TALFOURD, Sir THOMAS NOON, D.C.L., 1795-1854; b. England; studied law; was a member of parliament from 1835-41, and 1847-49, when he received an appointment as judge of the court of common pleas. He advocated in parliament the rights of authors, and introduced in 1837 the copyright act, which with a few alterations was passed in 1842. He wrote the tragedy of *Ion* in 1835, which was performed with great success, and subsequently *The Athenian Captive* (1838); *Glencoe* (1840); and *The Castilian* (1854). He also published *Memoirs and Correspondence of Charles Lamb* (1837); *Final Memorials of Charles Lamb* (1848), and *Vacation Rambles* (1844).

TALIAFERRO, a co. in n.e. Georgia; drained by the Ogeechee and Little rivers; traversed by the Georgia railroad; about 200 sq.m.; pop. '80, 7,034—4,724 colored. The surface is irregular. The soil is fairly fertile. The principal productions are corn, cotton, and live stock. Co. seat, Crawfordsville.

TALIAFERRO, BENJAMIN, about 1751-1821; b. Va.; a member of Morgan's rifle corps; served at Saratoga, Monmouth, and Savannah, greatly distinguishing himself for coolness and daring on the field. He was aid-de-camp to gen. Lincoln at Charleston in 1780, and was taken prisoner. In 1784 he removed to Georgia; delegate to the Georgia state constitutional convention, 1798; member of congress 1799-1802, and filled the office of judge of the superior court, state senator, and president of the state senate.

TALIESIN, a Welsh bard, said to be the son of Hweng, and supposed to have lived in the 6th century. He was called the "chief of the bards," and was, with the two Merlins, the most celebrated among the Christian bards. The *Archæology of Wales* contains some pieces said to be his.

TALIPAT PALM, or Great Fan Palm, *Corypha umbraculifera*, the noblest palm of the East Indies, a native of Ceylon, Malabar, etc. It grows to the height of 60, 70, or even 100 ft., and has a straight cylindrical trunk, crowned with a tuft of enormous palmate plaited leaves, which are divided near the outer margin into numerous segments, and are united to the trunk by spiny leaf-stalks. The leaves are usually about 18 ft. long, exclusive of the leaf stalk, and 14 ft. broad; a single one being sufficient to protect 15 or 20 men from rain. At the age of 30 or 40 years the tree flowers, and, after ripening fruit, generally dies. It produces a long conical erect spadix, rising to the height of 30 ft. from the midst of its crown of leaves, and dividing into simple alternate branches, the lower of which sometimes extend laterally 20 ft., the whole covered with whitish flowers, and forming a very beautiful and magnificent object. The fruit is very abundant, globose, and about an inch and a half in diameter. The leaves are used for covering houses, for making tents, and for many other purposes. On occasions of ceremony every Singhalese noble is followed by an attendant, who carries above his head a richly ornamented talipat palm leaf, which is capable of being folded up like a fan, and is then not thicker than a man's arm, and wonderfully light. The leaves of this palm are used in Malabar for writing upon, characters being traced upon them with an iron style. They are prepared for this purpose by boiling, drying, damping, rubbing, and pressing. The soft central part of the stem, pounded and made into bread, has often been of great use in times of scarcity.

TALIPÉS, the scientific name for CLUB-FOOT (q.v.). It is derived from the Latin words *talus*, the heel, and *pes*, the foot.

TALISMAN (Arabic, but supposed to be derived from the Gr. *telesma*, in the sense of celebration of religious ceremonies), a species of charm, consisting of a figure engraved on metal or stone when two planets are in conjunction, or when a star is at its culminating point, and supposed to exert some protective influence over the wearer of it. The terms talisman and amulet (q.v.) are often considered nearly synonymous, but the proper distinctive peculiarity of the former is its astrological character. Talismanic virtues have often been attributed to a peculiarly marked or formed egg, and instances are recorded, by various authors, of eggs hatched with figures of comets or eclipses on them. A species of talisman, which has acquired considerable celebrity is the Abraxas stone (q.v.). A species of talisman at present in use in Asia, is a piece of paper on which the names of the seven sleepers and their dog are inscribed. Pasted on the walls of houses, it is believed to be a protection against ghosts and demons.

TALLADEGA, a co. in n.e. central Alabama; drained by the Coosa river and Choccolocco creek; traversed by the Selma, Rome and Dalton railroad; about 750 sq.m.; pop. '80, 23,360—12,504 colored. The surface is somewhat hilly, and much of it woodland. The soil is fertile. The principal productions are corn, cotton, wheat, and cattle. Co. seat, Talladega.

TALLADEGA, a city in n.e. Alabama, co. seat of Talladega co.; on the Selma, Rome and Dalton railroad; pop. '80, 1,232. It is built on the battle ground where gen. Jackson gained a victory over the Creek Indians in 1813, and is 85 m. n.e. of Montgomery and 110 m. from Selma. It is the seat of Talladega college, incorporated, 1869; supported by the American missionary society, for the education of white and colored of both sexes. The college has a preparatory, theological, and normal course, a primary, intermediate, and grammar department. In 1874-75 it had 13 instructors and 247 students. The city is also the seat of the state institution for deaf and blind, and of a Presbyterian female seminary. It contains 6 churches, supports 2 newspapers, has a court-house, a bank, and an important trade in cotton and wheat.

TALLAGE (said by lord Coke to be from Fr. *tailler*, to share or cut out a part), a name which has been sometimes applied generally to subsidies or taxes of every kind, but which, in its more proper and restricted sense, denotes those taxes to which, under the Anglo-Norman kings, the demesne lands of the crown and all royal towns were subject, which were far more rigorous and irregular than the taxes imposed on the gentry.

TALLAHASSEE, the capital of Florida, situated on a high plain, 180 m. e. of Pensacola, a well-planned, and so far well-built embryo city. It is celebrated for its salubrious, semi-tropical climate, and abundant springs of soft pure water. It is a station on the Jacksonville, Pensacola and Mobile railway, at the junction of a branch to St. Marks, 23 m. distant on the coast. Pop. '70, 2,023.

TALLAHASSEE (*ante*), a city, in n. Florida, incorporated, 1827; capital of the state, and co. seat of Leon co.; pop. '80, 2,494. It is 165 m. w. of Jacksonville, and 230 m. e. of Mobile. Its public buildings are beautifully shaded by oak and evergreen trees, and are built mostly of brick. It is the seat of the West Florida seminary, situated on a hill commanding a view of the city, a state institution for both sexes but with separate departments. The institution is supported by the proceeds of the sale of government lands, granted by congress to the state, and called the "seminary lands." There are public schools, 5 churches, 2 newspapers, and cotton factories.

TALLAHATCHIE, a co. in n.w. Mississippi, drained by the Tallahatchie river and several creeks; traversed by the Mississippi and Tennessee railroad; 750 sq.m.; pop. '80, 10,926—10,880 of American birth, 6,757 colored. The surface is level and in part swampy; cotton, corn, pork, and cattle are the staples. Co. seat, Charleston.

TALLAPOOSA, a co. in e. Alabama; drained by the Tallapoosa river and Sandy creek; traversed by the Savannah and Memphis railroad; 770 sq.m.; pop. '80, 23,400—23,376 of American birth, 7,295 colored. The surface is rough and heavily wooded: cotton, corn, cattle, wheat, and pork are staples. Co. seat, Dadeville.

TALLEYRAND-PERIGORD, CHARLES MAURICE DE, Prince of Benevento, the most subtle, shrewd, and unprincipled of all modern diplomatists, was b. at Paris, Feb. 13, 1754, of an ancient and distinguished family. His father, CHARLES DANIEL, COMTE DE TALLEYRAND-PERIGORD (b. 1734, d. 1788), was an officer in the French army, and fought all through the seven years' war. CHARLES MAURICE being the eldest son, would in all probability have been designed for a military career had not an accident which he met with when only a year old, rendered him lame for the rest of his life. He was, in consequence, trained for the church, and studied at St. Sulpice, the Sorbonne, and Rheims, but at no period did he betray the least inclination toward a Christian or even a moral life. At the age of 20 he came to Paris and rapidly acquired a reputation for licentiousness. This, however, did not prevent him from obtaining several ecclesiastical benefices, among others the abacy of St. Denis, in the diocese of Rheims (1775). Appointed *agent général* for the clergy in 1780, a lucrative and important post, which brought him into close connection with the heads of the administrative in France, he now began a serious apprenticeship to public business, without, however, pausing in his career of gallantry. So notorious was his *infâme conduite* (as Mirabeau calls it), that for some years Louis XVI. shrank from conferring on him further ecclesiastical preferment, and it was only on account of his administrative abilities that in 1788 he obtained the bishopric of Autun. When the convocation of the *états-généraux* took place in the year following, he was elected by the clergy of his diocese to represent it, and pronounced in favor of an amalgamation with the *tiers état*, which on June 17 had constituted itself the *assemblée nationale*. His attitude and speeches recommended him to the notice of the popular party, and along with Mounier, Sieyès, and Lally-Tolendal, he was appointed to draw up a constitution for the nation. In this capacity he took an active part in framing the famous declaration of rights, and he was one of those selected (after the destruction of the Bastille) to investigate the causes and peculiar features of the revolutionary movement. It was Talleyrand who proposed (Oct. 10, 1789) the startling measure for the confiscation of church property, arguing that such property did not really belong to the church, but to the nation, and that if the rights of the existing clergy were secured, the nation or its representatives were at liberty to apply it to any purpose they saw fit. On Feb. 13, 1790, a decree for the suppression of religious orders was carried in spite of a vehement opposition, and three days after Talleyrand became president of the assembly. He was one of the first among his order to take the oath to obey the constitution (Dec. 28, 1790), and he eagerly urged the clergy of his diocese to follow his example. About the same time he demitted his bishopric of Autun, yet in the following February we read of his consecrating two new bishops (those of Aisne and Finisterre), and although denounced in pontifical briefs as a schismatic, declaring his sincere attachment to the holy see!

Our space does not permit us to describe the important share that Talleyrand had in the financial deliberations of this first period of the revolution, but we must specially note the sagacity he displayed in pointing out the perils attending the issue of assignats, his skill in preparing the way for the adoption of the principle of uniformity in weights and measures, and of an arc of a meridian as the basis of the new metrical system; and, above all, the luminous intelligence shown in the report which he gave in to the assembly (Sept. 10 and 11, 1791) upon public instruction—a report conceived in the liberal and comprehensive spirit of the times, and which was undoubtedly the model followed in all the great changes that subsequently took place when France reorganized her educational system.

In 1792, when the old European despotisms were obviously preparing to coerce the young republic, Talleyrand was sent to London—but not in an official character—to negotiate with the English government. He did not make a favorable impression on George III. or on Pitt. Thrice in that year he essayed to procure a recognition of the republican government, but in vain. The "September massacres" (see SEPTEMBERISTS) made even the staunchest admirers of the revolution shudder. Nothing, therefore, could be done; and Talleyrand would doubtless have returned to France had not a letter of M. de Laporte, *intendant* of the civil list of Louis XVI., been discovered, in which Tal

leyrand was noted as a man "disposed to serve" the king. He was immediately placed on the list of *émigrés*, i.e., proscribed (Dec., 1792); and thus his connection with the revolution—fortunately, we believe, for his reputation—was suddenly brought to a close. His career as an exile was (as is generally the case) one of hardship and insignificance. He remained in England till forced to leave by the "alien bill," when he sailed for the United States (Feb., 1794), where he lived for more than a year. After the fall of the terrorists he procured the revocation of his banishment, and in March, 1796, re-entered Paris, having paved the way for a favorable reception by a series of the most adroit and judicious intrigues. We may first note, *en passant*, that in private life he continued to play the rôle of a gay Lothario.

Talleyrand attached himself to the *cercle constitutionnel* that gathered round Mme. de Staël, and so dexterously did he comport himself, that in 1797 he was named minister of foreign affairs in place of C. Delacroix. The rise of Bonaparte was a phenomenon which so penetrating a politician as Talleyrand could not overlook. He cultivated the friendship of the young gen. with a sagacious assiduity, keeping him constantly *au courant*, when away from Paris, of the situation of parties, and became his confidant in those designs, the execution of which resulted in the overthrow of the directory, Brumaire 18 (q.v.), 1799. After this *coup d'état* the subtle finesse of Talleyrand was constantly in requisition. He divined, with a sort of miraculous cleverness, the ideas of Bonaparte, and his whole policy was directed to consolidate the power and authority of his master. In all the diplomatic negotiations that followed the victories of France under the consulate he had the principal part; but Bonaparte thoroughly understood his man, and Talleyrand was quite conscious, as M. Thiers remarks, that he could never impose on his superior. It was he who proposed the kidnapping of the duke d'Enghien (q.v.); and it was by his instructions that the crime was consummated, in spite of the vehement opposition of Josephine, whose honest indignation led her to denounce him as a *maudit boiteux* (cursed cripple). Talleyrand took an active part in preparing the way for the establishment of the empire (1804); and when in the following year England, dreading a French invasion, formed a powerful European coalition against France, it was by the ingenuity of Talleyrand that it was partly broken up. To him, as much as to Napoleon, was owing the organization (1806) of the famous *confederation of the Rhine* (q.v.), which so effectually served the ambitious designs of the emperor. In conducting the negotiations that brought about this confederation he exhibited a truly Machiavelian art. Napoleon was not ungrateful. Talleyrand received the principality of Benevento, which he held as an imperial fief.

When the views of the emperor in regard to Spain became apparent, Talleyrand, who for more than a year had rather fallen into disfavor with Napoleon, came forward with a plan of his own, which, however, was not adopted; but his presence at the interview between Alexander and Napoleon at Erfurt (1808) proved that his influence was as yet undiminished. The ill success of the Spanish war (at first) induced Talleyrand to pronounce against it, and occasioned violent invectives on the side of his sovereign, to which the accomplished cynic (who retained to the last the manners of the old noblesse) only replied by the sarcasm: "*Quel dommage qu'un si grand homme soit si mal élevé!*" (What a misfortune that so great a man should have been so badly educated!). Talleyrand declared in favor of the Austrian marriage; but already the *entente cordiale* between him and Napoleon was ruptured, and he began to look forward to a future in which his own schemes might be hostile to those of the emperor. In a word he was meditating treachery against the power by which he had risen. The victories of Wellington in Spain, and the reverses of Napoleon in Russia and Germany, widened the breach between them, and Talleyrand now only waited the decisive moment in which to ruin the cause of his master. He became the center of a group of Parisian malcontents whose influence grew with the advance of the allied armies, and finally communications were opened up with the latter and with the Bourbons. It was Talleyrand who dictated to the senate the terms of the deposition of Napoleon; and on the restoration of the Bourbons he became minister of foreign affairs in the first government of Louis XVIII. He was also head of the French legation in the celebrated congress of Vienna; but after the battle of Waterloo a coldness sprung up between him and the Bourbons, and he was relieved of all his offices. Henceforth his career is uninteresting to the student of history. He caballed to regain power, but in vain; and during the reigns of Louis XVIII. and Charles X. he was merely a discontented senator, who never lost an opportunity of injuring the court and the government. After the July Revolution, Louis Philippe employed him as ambassador at the English court, where he contrived to bring about a friendly feeling between the new monarchy and the English government. During the brief remainder of his life nothing externally notable occurred. He died at Paris May 17, 1838. Talleyrand was neither a wise, nor a great, nor a good man; but he was infinitely cunning, dexterous, and supple. He had a larger share than most men of what Carlyle calls "vulpine understanding;" and if this world had had nothing but knaves and fools in it, the policy and principles of Talleyrand might have enjoyed a perpetual triumph; but there were forces in the world, both intellectual and moral, of which he took no account, but which took account of him, and, with all his amazing cleverness, dropped him into obscurity and disgrace. Talleyrand was an 18th c. skeptic, over whom the revolution had exercised little influ-

ence, while France, and indeed all Europe, had been roused into earnestness by the outburst; and when the ideas of political liberty began their swift, irresistible march, this *diable boiteux* inevitably lagged behind, and sunk out of sight. Talleyrand has left *Mémoires*, which are not to be published till 1890. For estimates of his character and policy, see the *Mémoires Politiques* of Lamartine; the *Histoire de Dix Ans* of Louis Blanc, where Talleyrand is rigorously criticised; the *Mémoires* of Guizot, where he is handled with equal severity and justice *Notices et Portraits*, by Mignet; and *Vie Religieuse et Politique de Talleyrand* (Par. 1838), by L. Bastide.

TALLICOO NAH OIL. See CARAPA.

TALLIEN, JEAN LAMBERT, a French revolutionist, was born at Paris in 1769, and first became notable in the beginning of 1792 as the editor of a Jacobin journal, called *L'Ami des Citoyens*, meant to be a friendly rival of Marat's *Ami du Peuple*. From this date his influence over the lower orders of the city steadily increased. He was conspicuous in the events of August 10, and in consequence received the appointment of secretary to the *Commune Insurrectionelle*. He promoted and afterward defended the massacres of September; and on account of his unscrupulous zeal, was elected to the convention by the department of Seine-et-Oise. There he became the apologist if not the advocate of Marat, denounced the minister Roland, urged with savage emphasis the condemnation of Louis XVI., and was rabidly eager for the ostracism and annihilation of the Girondists (q.v.). Toward the close of 1793 he was sent to Bordeaux, charged with the mission of destroying every trace of the party he hated. His career in the south-west was a mixture of reckless cruelty and shameful vice. To the odious tyrannies of a proconsul he added the luxurious profligacy of a satrap. Fortunately for his countrymen, a passion which he conceived for one of his victims, Madame de Fontenay (née Cabarrus), led him to pause in his bloody course. He was called to Paris to account for this singular change in his disposition, satisfied his associates (by paroxysms of patriotic vehemence) that it meant nothing particular, and on March 22, 1794, was chosen president of the convention. Robespierre, however, had found out the sort of man that Tallien was. He hated him for his insincerity and immorality, felt instinctively that he could not be trusted, denounced him severely in the convention, and on June 14 got his name erased from the list of members at the Jacobins. Tallien recognized his danger, and taking advantage of the reaction against the terrorists (though himself one of the basest of the set), already beginning to show itself in France, he dexterously rallied the Dantonists, Hebertists, and others against the rigorous government of Robespierre, St. Just, and Couthon, and brought about the events of the 9th Thermidor (July 27, 1794), which caused the fall of the triumvirate. Tallien now became for a short time one of the most notable and influential men in France; lent his aid to suppress the revolutionary tribunal and the Jacobin club, and drew up the accusations against Carrier, Le Bon, and others of the terrorists! But France could not long tolerate this affectation of virtue on the part of one so infamous: his past life was perpetually held up to scorn and reproach; and finally, on May 20, 1798, he was forced to leave the council of five hundred. Henceforth his career is pitifully insignificant. He accompanied Bonaparte to Egypt as *savant* (!), quarreled with gen. Menou, and on his return to France, was captured by an English cruiser, and brought to England, where the whig opposition was stupid enough to make a hero of him (1801). Soon after he returned to France, and was contemptuously dismissed as consul to Alicante by Talleyrand, outlived (in utter obscurity) the empire of Napoleon, and died at Paris, Nov. 16, 1820, supported in his last days by the heirs of the monarch for whose death he had inhumanly clamored.

TALLIS, THOMAS, 1529-85, b. England; was organist to queen Elizabeth. He has been called the father of "English cathedral music." He published with William Byrd, *Discursus Cautiones Sacre*, for which he was granted a patent for 21 years from the queen; *Order of Daily Service*; *Full Cathedral Service*; *Order for Morning Prayer with the Litany* Noted.

TALLMADGE, BENJAMIN, 1754-1835; b. N. Y.; graduated Yale college, 1773; principal of a high school at Wethersfield, Conn.; entered the continental army; became lieutenant, adjt., and col. of a Connecticut regiment, 1776; surprised and captured 500 tory marauders at Lloyds' Neck, L. I., Sept. 5, 1779, without losing one of his men; planned and led the expedition which took fort George, Oyster bay, and destroyed the British stores on Long Island, 1780; was in some of the principal battles of the war, had charge of maj. André until the execution of his sentence; was one of Washington's military family, and conducted his secret correspondence; was a successful merchant after the war, and a member of congress, 1801-17. His *Memoirs* were published by his son.

TALLMADGE, FREDERICK AUGUSTUS, 1792-1869; b. Conn.; graduated at Yale college, 1811; studied law at Litchfield, and was there admitted to the bar. He practiced with great success in New York, where he held the offices of recorder, superintendent of police, and clerk of the court of appeals. He was a state senator in 1836, and about the same time a judge of the supreme court of errors. At the "Astor place riot" of 1849 he showed great firmness in restoring order.

TALLMADGE, JAMES, LL.D., 1778-1853; b. N. Y.; graduated at Brown university, 1798; practiced law, but gave his attention chiefly to agriculture; was for some time private secretary of governor George Clinton, and in the war of 1812 commanded the troops that defended New York; was a member of congress, 1817-19, and to a bill for the organization of Missouri into a state, he offered an amendment restricting slavery to the region w. of the Mississippi; was a member of legislature, 1824; lieutenant governor, 1826-27. In 1835 he visited Europe, and introduced American machinery into Russia.

TALLOW. See OILS AND FATS.

TALLOW, MINERAL. See MINERAL TALLOW.

TALLOW TREE, the name given in different parts of the world to trees of different kinds which produce a thick oil or vegetable tallow, or a somewhat resinous substance, which, like tallow, is capable of being used for making candles. Tallow tree of Malabar (*raterie indicæ*) is a very large tree of the natural order *dipterocarpaceæ*. It has leathery leaves of 4 to 10 ft. long, and panicles of white, fragrant flowers, with five petals. The stem is often 16 ft. in circumference. By incisions in the stem, east Indian copal is got; and by boiling its seeds, there is obtained a firm, white, vegetable tallow, which, as it has no unpleasant smell, is particularly suitable for making both candles and soap.—The tallow tree of China (*stillingia sebifera*) belongs to the natural order *euphorbiaceæ*. The capsules are internally divided into three cells, each containing a nearly hemispherical seed, which is covered with a beautifully white vegetable tallow. This the Chinese collect for the manufacture of candles, in order to which, the capsules and seeds are crushed and boiled, and the fat skimmed off while in a melted state. To give it a firmer consistency, wax is added to it, in the proportion of three parts to ten of the vegetable tallow. Linseed oil is also added. The candles made of it are beautifully white. This tree has been introduced into North America, is cultivated about Charlestown and Savannah, and is almost naturalized in the maritime parts of Carolina. It presents a very beautiful and remarkable appearance at the approach of winter, when the leaves become bright red, and the pericarps falling off, leave the white seeds suspended by threads.—The name tallow tree is sometimes given in North America to a species of *Candleberry* (q.v.).—The tallow tree, or **BUTTER AND TALLOW TREE** of Sierra Leone, is *pentadesma butyracea*, of the natural order *guttifera*, the fruit of which furnishes a solid oil.

TALLY (Fr. *tallier*, to cut), the name given to the notched sticks which, till a recent period, were used in England for keeping accounts in exchequer, answering the double purpose of receipts and public records. They were well seasoned rods of hazel or willow, inscribed on one side with notches indicating the sum for which the tally was an acknowledgment, and on two opposite sides with the same sum in Roman characters, along with the name of the payer and the date of the transaction. Different kinds of notches, differing in breadth, stood for a penny, a shilling, a pound, £20, £100, and £1000. The tally was cleft through the middle by the deputy-chamberlain with knife and mallet, so that each piece contained one of the written sides, and a half of every notch; and the one-half was retained by the payer as his receipt, while the other was preserved in exchequer. At the union of England and Scotland, a store of hazel rods for tallies was sent to Edinburgh, but never made use of. Act. 23, Geo. III. c. 82 abolished the use of tallies in exchequer, and the old tallies were ordered to be destroyed by 4 and 5 Will. IV. c. 15. The destruction of the houses Parliament by fire in 1834 is supposed to have arisen from the over heating of the flues in which the discarded tallies were being burned.

TALLY SYSTEM is the name given to a mode of buying goods much in vogue among the wifes of poor men, whereby they get goods, chiefly articles of dress and cheap finery, on credit, or on terms of payment by small weekly sums till the debt is paid. It, in point of law, gives rise to the following hardships and disadvantages whenever, as is usually the case, the wife, in the absence of, and without the knowledge of, the husband, enters into the contract, and purchases goods which are beyond her station. The husband, when sued in such a case on the contract, can set up a good defense. If he had given his wife sufficient clothes, either in specie or the means of buying them, he is not liable to pay any tradesman who, without his sanction, supplies the wife with more, especially if these are articles of finery. It is only in the case of the articles being strictly called necessities, that he will be bound at all; and as regards women of the lower classes, a court or jury would construe the word "necessaries" very strictly in favor of the husband. If the articles are extravagant, and beyond the station of the wife, the husband is then not liable to pay for the price, and no court will compel him to do so. The only ground on which he can be made liable will be, that the husband knew of the purchase, and directly or indirectly sanctioned it; as, for example, by seeing her wear the clothes, and not returning them, or giving immediate notice to the tallyman that he objected to the purchase. Nevertheless, it must be confessed that judges are not uniform in their decisions, and some too easily give effect to the contract, for want of strong evidence on the part of the husband of the earliest disavowal of it he could make. The tallyman generally makes it a stipulation that the bargain shall be kept secret for a certain length

of time. Nevertheless, if, when it is discovered, the husband at once repudiates and returns the articles, it is the tallyman's own fault if he is then obliged to take them back after they have been partly used, and he cannot fix the husband with liability.

TALMA, FRANÇOIS JOSEPH, an eminent French tragedian, was the son of a dentist, and was b. at Paris, Jan. 15, 1763. He made his *début* as an actor in 1787 at the Comédie Française, where he played the part of Scide in *Mahomet*. He achieved considerable success, but apparently not enough to excite any very high anticipations of his future career, and for upward of a year he figured only in secondary characters. The first thing that induced the public to notice him attentively was an innovation in the matter of costume when playing the part of Proculus in the tragedy of *Brutus*. Previously, actors had worn the garb of their own country, and even their own time; and Roman senators stalked about the stage dressed as Parisian "swells" of the 18th century. The absurdity of this fashion forcibly struck Talma, who set himself to amend it, and in the part referred to appeared in the green-room clothed in a Roman toga, greatly to the astonishment of the company, one of whom (Louise Contat) exclaimed: "Good God! look at Talma; how ridiculous he is! *Why, he has quite the air of an ancient statue!*" The compliment was as exquisite and as just as it was unintentional. Henceforth, a rigorous accuracy in costume became a point with Talma; but his first grand triumph in acting was won, Nov. 4, 1789, when he played Charles IX. in Chenier's piece of that name. During the revolution he was in the zenith of his popularity, and made peculiarly his own such characters as Abdélazis, in *Abdélazis et Zuléma*; Othello; Néron, in *Epicharis et Néron*; Pharan, in *Abulfar*; and Egisthe, in *Agamemnon*. Exceedingly arrogant and choleric, he was often at strife, either with the public or with some of his fellow-actors. Talma was a favorite with Napoleon and Louis XVIII. Some of his later characters were among his best, as Marigny, in *Les Templiers*; Leicester, in *Mary Stuart*; Sylla; Oreste in the *Cytemnestre* of Soumet; Leonidas; and Charles VI. He died Oct. 19, 1826.

TALMAGE, THOMAS DE WITT, D.D., b. N. J., 1832; graduated at New York university, 1853; studied theology at New Brunswick, and in 1856 became pastor of the Reformed church in Belleville, N. J.; in 1859 received a call to the Reformed church in Syracuse, N. Y.; and from 1862 to 1869 was settled in Philadelphia. In the latter year began his connection with the Brooklyn Central Presbyterian church, over which he is still pastor. The original "Tabernacle" was erected in 1870, and destroyed by fire in 1872. In 1874 a new building of brick and stone and of Gothic style, with a seating capacity of 4,600, was dedicated. This is the largest Protestant church in this country. Mr. Talmage has published *The Almond Tree*; *Crumbs Scept Up*; *Abominations of Modern Society*; *Sports that Kill*; *Every-day Religion*; and other writings. He was for several years editor of *The Christian at Work*. In 1879 charges of falsehood and dishonorable business conduct were brought against Dr. Talmage before the Brooklyn presbytery. He was acquitted, and the decision was sustained by the synod and (May, 1881) by the assembly.

TALMUD (from Heb. *lamad*, to learn)—i.e., study, by way of eminence—is the name of the fundamental code of the Jewish civil and canonical law, comprising the Mishna (q.v.) and the Gemara (q.v.), the former as the text, the latter as the commentary and complement. We have spoken under HALACHA and HAGGADA of the gradual development of this "oral," or, chronologically speaking, post-Mosaic code. We have also there mentioned the older collections upon which the Mishna was framed, and finally redacted in the form in which we now possess it. The oldest codification of Halachoth, or single ordinances, is due to the school of Hillel (q.v.). Simon ben Gamaliel the patriarch (166 A.D.) and his school carefully sifted the material thus brought together; and in the following generation, through Jehudah Hanassi (219 A.D.) and his disciples, the work was brought to its close in six portions (Sedarim), 63 treatises (Mesechtoth), and 524 chapters (Perakim), which contain the single Mishnas. A summary of its contents is given under MISHNA. But besides this authoritatively compiled code, there were a number of other law collections, partly anterior to it, and not fully embodied in it, partly arising out of it—as supplements, complements, by-laws, and the like—partly portions of the ancient Midrash (q.v.); partly either private text-books composed by the masters of the academies for their lectures or enlargements of the existing Mishna. All this additional legal material was collected, not rarely together with the dissensions which begot it, under the name of *Boraitoth*, by Chija and his school, in the succeeding generation. Not to be confounded with them, however, are the collections of *Toseftas* or *Great Mishnas*, which, commenced at the time of Jehudah Hanassi himself, and continued after his death by Chija and Hoshaja, embody much of what has been purposely left out in the concise Mishna; that only embraced the final dicta and decisions. Such "additions" we possess now to 52 treatises, forming together 383 perakim, or chapters. All these different sources of the "oral law"—finally redacted before the end of the 3d c., though probably not committed to writing until 550 A.D.—belong to the period of from about 30 B.C. to about 250 A.D. This great mass of legal matter, although apparently calculated to provide for every case, if not for all times, was yet found insufficient. The dicta of later masters, the decisions of the courts, the discussions on the meaning and purport of special traditions, the attempts at reconciling apparent contradictions in the

received material, the amplifications or modifications of certain injunctions rendered necessary by the shifting wants and conditions of the commonwealth—all these and a number of other circumstances made a further codification peremptory.

We must not omit to state here, that this Mishna (Mathnisin), although it contained nothing but what were indigenous laws and institutions, was yet not a little influenced—if the very fact of its redaction was not indeed caused—by the spirit of the times. At Berytus, at Alexandria, at Rome, the legal schools were then in their most vigorous stage of development, and everywhere system and method were being introduced into what till then had been a vast complex of traditional and popular institutions, decrees, and decisions. The Mishna, in all respects, fulfilled the conditions reasonably to be demanded from such a text-book as it was intended to form; it was clear, concise, complete, and systematic, and moreover, composed in as classical a Hebrew as still could be written in those days of decadence of the “sacred language.”

The further development of this supplementary, oral, or second law, in fact, rather an exegesis thereof, together with the discussions raised by apparent contradictions found in the individual enactments of the Mishnic doctors, is called *Gemara* Discussion, Complement, or, according to another explanation, Doctrine. Whatever the original meaning of the root (*gamar*), it certainly allows of all the significations. This *Gemara* contains, apart from the Halacha (q.v.), which is generally written in Aramaic, also a vast number of non-legal, chiefly Hebrew, fragments—homiletic matter, tales, gnomes, legends, and the like—called *Haggada* (q.v.).

There are two Talmuds, the one called the Talmud of the Occidentals, or the “Jerusalem” (Palestine) Talmud, which was closed at Tiberias, and the other, the “Babylonian” Talmud. The first of these now extends over 39 treatises of the Mishna only, although it once existed to the whole of the first five *Sedarim* or portions. Its final redaction—falsely attributed to R. Jahanan (died 279)—probably belongs to the end of the 4th c. A.D.; but the individual academics and masters through whom it received its completion cannot now be fixed with any degree of certainty. There is less discussion and more precision of expression in this than in the second or Babylonian Talmud, emphatically styled “our Talmud,” which was not completed until the end of the 5th c., and which makes use of the former. As the real editor of the Babylonian Talmud, is to be considered Rabbi Ashe, president of the academy of Syra in Babylon (365–427 A.D.). Both the Mishna and the Palestine *Gemara* had, notwithstanding the brief period that had elapsed since their redaction, suffered greatly, partly by corruptions that had crept into their (unwritten) text through faulty traditions, partly through the new decisions arrived at independently in the different younger schools—of which there flourished many in different parts of the Dispersion—and which were at times contradictory to those arrived at under different circumstances in former academics. To put an end to these disputes, and the general confusion arising out of them, which threatened to end in sheer chaos, R. Ashe, aided by his disciple and friend Abina, or Rabina (abbr. from Rab Abina), commenced the cyclopean task of collecting anew the enormous mass of Halachistic material which by that time had grown up. The method he pursued was simple enough. His disciples met twice a year at Syra, in spring and in autumn. At the spring gathering, he gave out all the paragraphs of one treatise; and the disciples had the task to find out until the autumn meeting what opinions the different schools had pronounced on the special points thereof. He then investigated the whole critically, and put it into shape according to a certain order. This process took him, with the assistance of ten secretaries, no less than thirty years; and another thirty years were spent by him in the revision of the work, with which he proceeded in the same manner as he had done with the compilation itself. The final close of the work, however, is not due, as generally stated, to R. Jose, his successor at the academy (died 475), but to the school of the Saburaim at the end of the 5th century.

The Babylonian Talmud, as now extant, comprises the *Gemara* to almost the whole of the 2d, 3d, and 4th *Sedarim* (portions), further to the first treatise of the first, and to the first of the last order. The rest, if it ever existed, seems now lost. The whole work is about four times as large as the Jerusalem one, and is 36 treatises, with the commentaries generally added to them in our editions (Rashi and Tosafoth), till 2,947 folio leaves. The language of the Talmud its, as we said, Aramaic (western and eastern), or “Chaldee,” closely approaching to Syriac. The minor idiomatic differences between the two are easily accounted for by the different time and place; but the additional matter—quotations and fragments from older Midrash and *Gemara* collections, *Haggada*, etc.—is, as before stated, principally written in Hebrew.

The masters of the Mishna (Tanaim) and of the *Gemara* (Amoraim) were followed by the Saburaim (see above). The code of the oral law had come too close with the second named; and not its development, but rather its proper study, elucidation, and carrying into practice, was the task of the generations of the learned that followed. Apart from this, the Aramaic language itself began to die out as the popular language, and required a further study. The Saburaim no longer dared to contradict, but only opined on the meaning and practicability of certain enactments, and undertook the task of inculcating and popularizing the teachings laid down by their sires: apart from bestowing proper care upon the purity of the text itself, and adding some indispensable glosses. Their activity was at its height in the 8th c., when Karaim (see JEWISH SECTS), which utterly

denied the authority of the Talmud, sprang into existence. Respecting, however, this authority of the Talmud itself, there has never been anything approaching to a canonicity of the code, or of a reception of it as a binding law-book by the whole nation. The great consideration in which it was always held is owing partly to its intrinsic value, and to the fact of its becoming the basis of all further development of Jewish literature (it being undeniably the most trustworthy receptacle of the traditional Jewish law), and partly to a prosecution against the Jews in the Persian empire at the time of Jesdegerd II., Firuz, and Kobad, who closed the schools and academies for a space of nearly 80 years, during which this book was the sole authoritative guide of public conscience, and remained endowed with its importance ever when the schools were restored. The best commentaries of the Mishna are by Maimonides and Bartenora; of the Babylonian Talmud by Rashi (q.v.) and the *Tosafists* of France and Germany. An abstract of the Talmud for practical (legal) purposes by Maimonides (q.v.) is called *Mishne Thorah*. The Mishna was first printed at Naples, 1492; the Talmud of Jerusalem at Venice about 1523. The Babylonian Talmud was first published at Venice in 1520. It is generally printed in twelve folios, the text on the single pages being kept uniform with the previous editions, to facilitate the references. No translation of the Gemara has ever been carried further than a few single treatises. The complete Mishna, on the other hand, has been translated repeatedly into Latin, German, Spanish, etc., by Surenhus, Rabe, Jost, and others. We must refrain, in this place, from attempting a general characterization of the Talmud, a work completely *sui generis*. It will assuredly some day, when properly investigated, prove one of the most important records of humanity. Nothing can give even an approximate idea of the immensity of material, historical, geographical, philological, poetical, that lies hidden in its mounds. A contribution to the records of fanaticism may also be found in the "exoteric" history of the Talmud, which was, albeit utterly unknown save by a few garbled extracts, prohibited, confiscated, burned, and generally prosecuted and inveighed against by emperors, popes, theologians, and fanatics generally, from Justinian down almost to our own day, as perhaps no other book has ever been. In our own times, however, its value begins to be recognized by great scholars, not merely as the only source of the knowledge of Judaism, but as the chief source—next to the gospels—even for the history of the origin and early days of Christianity; a notion long ago hinted at by eminent divines like Lightfoot and others. See also *JEWS*, *MIDRASH*, *MISHNA*, *HALACHA*, *HAGGADA*; and an important essay in the *Literary Remains* of Em. Deutsch, author of the above article.

TALPIDÆ. See *MOLE*.

TALUS, a term employed in geology, to designate the sloping heap which accumulates at the base of a rock or precipice, from fragments broken off by the weather, or materials in any way carried over it. The term is also applied to the slope of a wall which diminishes in thickness as it rises.

TAMA, a co. in e. central Iowa; drained by Iowa river and Wolf creek; crossed by the Burlington, Cedar Rapids and Northern, and the Iowa division of the Chicago and Northwestern railroads; 720 sq.m.; pop. '80, 21,585—17,561 of American birth; 413 colored. The surface is in great part prairie; oats, wheat, hay, corn, and pork, are the staples. Co. seat, Toledo.

TAMANDUA, a species of the genus *myrmecophaga* or ant-eater (q.v.). The great ant-eater or *M. jubata* of Linneus, is called tamandua by the Portuguese, but ant-bear by the English and Spaniards. The proper tamandua, so called by the Portuguese of Brazil, is the *M. tamandua* of Cuvier, and is much smaller than the great ant eater, being about the size of a large common cat, and its head is not so disproportionately long, although it has much resemblance, and the same kind of snout and nostrils. Its length, from the root of the ear to the muzzle, is 5 inches. The greatest circumference of the head, just in front of the ears, is a little over 8 inches. The conformation of the extremities, the number of toes, before and behind, are in all respects the same as the great ant-eater, but it differs in having a prehensile tail, which is covered with short hair, as is also the body, while the great ant-eater has long, shaggy hair, and a bushy tail. The eyes of the tamandua are very small, as are also the round ears. The legs are short and robust. There are several varieties, chiefly distinguished by differences of color. It is a native of the thick forests of tropical America, and is said never to be found on the ground, but exclusively in trees, where it lives upon ants, honey, and it is said, even bees. When going to sleep it hides its muzzle in the fur of its breast, places its belly on a limb, and wraps the whole around with its tail. The female, as is the case with the great ant-eater, has two pectoral mammae and bears but a single cub at a birth, which she carries about on her shoulders for the first three or four months. It has a strong, disagreeable odor, which is perceptible at a great distance, especially if the animal is irritated. It is called *fourmillier* by the French, and little ant-bear by the English.

TAMAQUA, a borough in Schuylkill co., Pennsylvania, on the Little Schuylkill river, and on branches of the Philadelphia and Reading, and the Central railroad of New Jersey; pop. '70, 5,960. It has churches, schools, banks, and newspapers. It is the center of a district abounding in coal and iron. The shops of the Philadelphia and Reading railroad are here. Among its manufacturing establishments are breweries, foundries, rolling mills, machine shops, and saddle and harness factories.

TAMARACK. See LARCH.

TAMARA SPICE, a favorite mixture of condiments used by the Italians. It consists of powdered cinnamon, cloves, and coriander seeds in equal parts, and half the same quantity of aniseed and fennel-seed powdered.

TAMARIN, *Midas*, a genus of South American monkeys, small and beautiful, with short muzzle, prominent forehead, long nails, which, except on the hinder thumbs, are formed like claws, the tail longer than the body, not prehensile, and covered with hair so as to resemble the tail of a squirrel. The SILKY TAMARIN or MARAKINA (*M. rosalia*), is the best known of the genus. It is of a golden yellow color, with fine silky hair, of which it is exceedingly careful, to keep it free from stain. It is often brought to Europe, but is very tender, and seldom lives long. It is a very gentle and playful creature. The hair of the head and neck is elongated, so as to form a wig or mane; but this character appears far more strongly in the LITTLE LION MONKEY (*M. leonina*), which inhabits the eastern slope of the Cordilleras, and of which, although it is a very small animal, not many inches long, the appearance is an amusing caricature of that of the lion.

TAMARIND, *Tamarindus Indica*, a beautiful tree, of the natural order *leguminosæ*, suborder *Cesalpineeæ*, a native of the East Indies, but now very generally cultivated in warm climates. Only one species is known (*T. Indica*), a spreading tree, 30 or 40 ft. high, with alternate pinnate leaves, which have from 12 to 15 pair of small leaflets, and fragrant flowers, with three petals, the pods brown and many-seeded, as thick as a man's finger, and about six in. long. The pods are filled with a pleasant, acidulous, sweet, reddish-black pulp. It is brought to Europe, mixed with seeds and fibers, in the form of a mass resembling jam, from the East and West Indies, and the Levant. Tamarinds are generally preserved by throwing hot syrup on the ripe pulp; but a better method is to put alternate layers of tamarinds and sugar in a stone jar, the color and taste being thus more like those of the fresh pulp. The wood of the tamarind tree, and especially of its roots, is a cabinet wood of much beauty, but of extreme hardness, so that it is wrought with difficulty.—The pods of some other trees of genera allied to *Tamarindus* are filled with a similar pulp, which is used in the same way, as the tamarind plum of India (*dialium Indicum*), and the brown and velvet tamarinds of Sierra Leone, species of *codarium*.

On chemical analysis, tamarind pulp is found to contain citric, tartaric, and malic acids; potash, sugar, vegetable jelly, etc. As a salt of copper is a common adulteration, a piece of polished iron (a knife, for example) should be plunged into the pulp, and left in it for an hour, when, if copper be present, it will be deposited on the iron. Tamarind pulp is refrigerant and gently laxative; and in combination with more active remedies, is often employed in the diseases of children. It is used in India as a cooling article of food, and a kind of sherbet is also formed from it; it is also an excellent addition to curries. Tamarind tea is made by infusing tamarinds in boiling water; when cold, it forms an agreeable and cooling drink in inflammatory or febrile disorders. Tamarind whey is prepared by boiling one ounce of tamarinds with a pint of new milk, and straining: this also is an excellent cooling drink in similar cases.

TAMARISK, *Tamarix*, a genus of plants of the natural order *tamaricaceæ*. This order contains rather more than forty known species, all natives of the warmer parts of Europe and Asia, and of Africa, generally growing in arid situations. Some of them are herbaceous, others are shrubs or small trees, with rod-like branches, scale-like leaves, and small flowers in close spikes or racemes. The calyx has four or five segments; the corolla four or five petals; the stamens are hypogynous, equal in number to the petals, or twice as many; the pistil has three styles; the fruit is a one-celled capsule, with numerous hairy seeds. The COMMON TAMARISK (*T. Gallica*) grows in sandy places in the countries near the Mediterranean, and has been naturalized in some places on the southern coast of England. It sometimes attains a height of 30 feet. The twigs seem to possess tonic properties, and their medicinal virtues were once in high repute. The ashes of this and some other species of the genus contain much sulphate of soda.—The ORIENTAL TAMARISK (*T. orientalis*) is one of the few trees to be seen in the Arabian and African deserts, with the sands of which it seems to struggle more than any other tree or shrub. Its leafless appearance accords with the surrounding desolation. It is called *alé* or *ethel*, and its wood is used both for fuel and for many economical purposes.—Galls are found on some species in India, and are valued both for medicinal use and for dyeing. *T. mannifera*, perhaps a variety of *T. Gallica*, yields the kind of manna (q.v.) known as Mt. Sinai manna.—The GERMAN TAMARISK (*myricaria Germanica*) belongs to another genus of this order. It is a smaller shrub than the common tamarisk, and abounds in many parts of Europe and Asia, although not found in Britain. It was formerly supposed to possess valuable medicinal properties, but is now little regarded.

TAMATAVE, a t. on the e. coast of Madagascar, in lat. 18° 10's.; long. 49° 25' 30'e.; pop. '70, 7,500. The town is approached through narrow channels formed by coral reefs; is surrounded by palisades, and is the principal port on the island. The dwellings of the natives are of simple construction, with thatched roofs. The principal trade is

from the interior; its exports are india rubber, and hides; its imports are rum, brandy, shoes, sheetings, and salt.

TAMAULIPAS, a state in e. Mexico, bounded on the n. by Texas, on the e. by the gulf of Mexico, on the s. by Vera Cruz, and on the w. by Nuevo Leon and San Luis Potosí, drained by the Rio Grande del Norte, the Santander, the Tampico, the Fernando, and other streams; about 29,500 sq.m.; pop. '71, 108,778. The surface is uneven, and well wooded. Gold and silver are found. The soil is mostly fertile. The principal crops and fruits of both the temperate and torrid zones grow easily. Cattle, are the chief staple. Capital, Nuevo Santander.

TAMBOUR (Fr. *tambour*, drum), a frame upon which muslin or other material is stretched for embroidering. The tambour frame originally was made round. Tambour-work was extensively employed, for the decoration of large surfaces of muslin, etc., for curtains and similar purposes; but pattern-weaving has been brought to resemble it so closely, that it is being rapidly superseded.

TAMBOUR, in fortification, is a small work, usually a timber stockade, about 6 ft. high, and loopholed. Its object is to defend a gateway, the road into a village, or to afford flanking fire on a bridge, etc. The tambour on the covered-way is the traverse which closes an entrance from the glacis.

TAMBOURINE, a very ancient musical instrument of the drum species, much used by the Biscayan and Italian peasants at their festivities, and sometimes introduced into orchestral music where the subject of the piece is connected with a people who use it, as the Basques, gipsies, or peasants of the Abruzzi. It is composed of a piece of parchment, stretched on the top of a hoop furnished with little bells, and is sounded by the hands, fingers, or elbow. When sharply struck by the hand, the tambourine has not much effect, unless used in numbers. When sounded by gliding the fingers along the parchment, a roll results, in which the bells are chiefly heard; and by rubbing the parchment, without quitting it, with the whole weight of the thumb, the instrument gives out a wild, grotesque sound, which is sometimes of service in masquerade scenes.

TAMBOV, a government in the s.e. of Great Russia, bounded on the e. by the governments of Penza and Saratov. Area, 25,542 sq.m.; pop. '70, 2,150,971. The southern districts are hilly; the interior is a somewhat elevated plateau, with a gradual slope toward the north. Several lakes are found in the n. of the government, and the principal streams are the Tsna, an affluent of the Moksha, and the Moksha, which is itself an affluent of the Oka. The climate of Tambov, owing to its exposure to the biting n. winds, against which there is no protection, is more severe than in neighboring governments. The soil in the central and southern districts is a rich vegetable mold, and is very productive. In the n., clay predominates, and requires much manure. The chief agricultural products are rye, wheat, buckwheat, oats, hemp, and flax. The larger forests are found in the n., and pasture lands extend for the most part along the banks of the rivers. Agriculture and cattle-breeding are the principal employments; and some of the breeds of oxen, sheep, and horses, are excellent. Cloth, distilled liquors, tallow, and iron, are the chief manufactures. The products of the government are exported largely by the Tsna and the Moksha to the Oka and Volga.

TAMBOV, capital of the government of the same name, on the Tsna, 750 m. s.e. of St. Petersburg. It was founded in 1636 under the czar Michael Theodorovitch, and served as a fortress against Tartar invasion. It is regularly built, and, though the houses are mostly of wood, there are several important institutions, as the college, the military hospital, etc. Tambov is the seat of considerable manufacturing trade, there being in all 28 factories, in which cloth and sailcloth are extensively made. The chief articles of trade are leather, wool, tallow, and salt beef. Pop. '67, 28,617.

TAMBURINI, ANTONIO, b. Italy, 1800; made his début as a singer at Bologna in 1818. He soon gained a high reputation in Italy, and increased it in London and Paris, where he appeared in 1832. He had a powerful baritone voice, and was a good actor. He sang for several seasons in Bellini's *Puritani*, with Grisi, Lablache, and Rubini. His best part was "Don Giovanni." He retired from the stage in 1854, and took up his residence in France.

TAME ANIMALS, in point of law, render their owners subject to certain liabilities. There is no restriction as to what wild animals may be tamed; and the person who tames one, and retains possession, becomes the owner of it. There is, however, in all such cases an obligation on the owner to keep the animal with due care; and if it tends to be a nuisance to a neighborhood, he would, in extreme cases, be liable to an indictment, or in most cases, to an action of damages. If the animal tamed is naturally ferocious, then it is incumbent on the owner to keep it secure, so as not to allow it an opportunity of doing mischief; and in case of accidental escape, it is seldom that a jury will be persuaded that the owner is not guilty of negligence, and liable for the damage done. There is a certain class of animals which may exist in a wild state, yet by long use, or a second nature, have become domesticated, such as dogs and cats, and are called *mansuetæ naturæ*, in contradistinction to ferocious animals, such as lions. With regard to animals *mansuetæ naturæ*, the rule is, that the owner is only liable for mischief done by such animals when he has been guilty of some negligence in keeping such animals; and

in practice this amounted to saying that, if the owner was ignorant that the animal had once before done similar mischief, he would not be liable, unless he had omitted to take care to restrain that evil propensity. Thus, if a dog or cat, from some sudden whim, chose to attack some person, or other animal, not being incited to it by the owner, such owner is not at common law liable for the first offense; but in case of a second offense, he was generally held liable, at least whenever there was evidence of slight negligence superadded. Hence, if a dog worried sheep casually, the owner was held to be not liable, if it was the first offense. This state of the law was, however, found to work harshly, and a statute passed first for Ireland, then for Scotland, and lastly for England, the effect of which is to make the owner of a dog liable for damages caused by its worrying sheep, even though it is the first offense, and though the owner was not guilty of any negligence. These statutes passed in 1862, 1863, and 1865 respectively, and they establish an exception to the general rule, which still is in force, as to mischief done by dogs, other than worrying sheep—namely, that before the owner can be made liable, it must be proved that he knew of the dog or cat's mischievous propensity to do the act in question, and did not use due care in restraining it. This is the rule where, for example, a dog bites a person, or a bull gores a passenger. In short, negligence is the gist of the action, and more than mere ownership must be proved against the owner. Sometimes owners of lands plant spring-guns, traps, and similar implements, with a view to kill dogs, cats, and other vermin straying in such fields. The practice of placing spring-guns and man-traps, with a view to kill poachers, was found once to prevail, and created a great outcry about fifty years ago; and the legality of the practice was questioned, but the judges in England held, that if the man injured was a trespasser, the owner of the land was not liable; consequently, a statute was passed to make it illegal in future to place such engines, except in, and close to, dwelling-houses. In Scotland the judges held that the practice was illegal at common law, and no statute was necessary. But though man-traps put in fields are now illegal, traps which destroy dogs or cats are not so, with this qualification, however, that the traps must not be put near a highway, where the dog or cat might be lured aside when lawfully passing, as this would be taking too great an advantage of the instincts of the animal. As regards the stealing of tame animals, it was a technical defect in the common law of England that the offense of larceny could not be committed upon them; but by statutes it is provided that in most cases the offense of stealing or destroying tame animals is punishable either by fine or by imprisonment, in much the same way as larceny is punishable.

TAMERLANE. See TIMUR

TAMIL (more properly spelled *Tamir*, but erroneously written *Tamul*, and erroneously termed by the earlier Europeans "the Malabar") is the name of the language earliest cultivated of all the idioms which the rev. R. Caldwell designates as Dravidian—this term comprising, according to him, besides the Tamil, the Telugu; Canarese; Malayalam, or Malayārma; Tul'u, or Tul'ua; Toda, or Tuda, or Tudava; Kōta; Gōnd; and Khond, or Künd, or Ku. "The Tamil language," this learned author says in his *Comparative Grammar of the Dravidian or South-Indian Family of Languages*, "is spoken throughout the vast plain of the Carnatic, or country below the Ghauts, from Pulicat to cape Comorin, and from the Ghauts, or central mountain-range of southern India, to the bay of Bengal. It is also spoken in the southern part of the Travancore country, on the western side of the Ghauts, from cape Comorin to the neighborhood of Trivandrum; and in the northern and north-western parts of Ceylon, where Tamilians commenced to form settlements prior even to the Christian era, and from whence they have gradually thrust out the Singhalese. All throughout Ceylon, the coolies in the coffee-plantations are Tamilians; the majority of the money-making classes even in Colombo are Tamilians; and ere long the Tamilians will have excluded the Singhalese from almost every office of profit and trust in their own island. The majority of the domestic servants of Europeans, and of the camp-followers in every part of the presidency of Madras being Tamil people, Tamil is the prevailing language in all military cantonnments in southern India, whatever be the vernacular language of the district; hence, at Cannanore, in the Malayāla country; at Bangalore, in the Canarese country; at Bellary, in the Telugu country; and at Secunderabad, where Hindustani may be considered as the vernacular, the language which most frequently meets the ear in the bazaar is the Tamil. The majority of the *Klings*, or Hindus who are found in Pegu, Penang, Singapore, and other places in the further east, are Tamilians. . . . Including Tamilians resident in military stations and distant colonies, and the Tamilian inhabitants of s. Travancore and northern Ceylon . . . the people who speak the Tamil language may be estimated at *about ten millions*." "Tamil includes two dialects, the classical and the colloquial, or the ancient and the modern, called respectively the Shen-Tamil and the Kod'un-Tamil. The former is the language of poetry and of the ancient inscriptions; it contains fewer words borrowed from the Sanskrit than the colloquial Tamil, and among these chiefly such as express abstract ideas of philosophy, science, religion, and technical terms of the more elegant arts; and, in general, it so considerably differs from the colloquial Tamil that it is almost unintelligible to the unlearned Tamilian. Of all the Indian languages, Tamil has the most imperfect alphabet. The latter consists of 12 vowels—viz., *a, ā, i, ī, u, ū, e, ē, o, ō, ai, and au*—and of 18 consonants—viz., *k, ch, t, l, p, R, ng, ñ, n', n, m*, a final

n, y, r, l, v, r', l'. Compared to the Devanāgarī alphabet of Sanskrit, it is deficient therefore in the vowels *r'i, r'ī,* and *l'i,* though it possesses a short *e* and a short *o*, which the Devanāgarī has not; it has but one sound for *k, kh, g, gh;* for *ch, chh, j, jh;* for *t, th, d, dh;* for *l, th, d, dh;* and for *p, ph, b, bh.* It is destitute, moreover, of the Sanskrit aspirate *h,* of the Sanskrit sibilants, *s, ś,* and *sh,* and of Anuswara and Visarga. Of combined consonants, which abound in the Devanāgarī alphabet, it admits only the junction of the nasal and the mute, as *n-t, n'-t',* etc.; doubled nasals, as *n-n, m-m,* etc.; doubled surds, as *k-k, ch-ch,* etc.; also *tk, tp, Rk, Rch, Rp, yy, ll, ve,* and *nR;* of triple consonants, only *r'nd* and *gnd.* If Sanskrit derivatives, therefore, are Tamilized, various devices are resorted to in order to separate Sanskrit groups of consonants. Thus, Sanskrit *pra* becomes Tamil *pīra;* Sanskrit *krishn'a* becomes Tamil *kirat' tīna-n* or *ki' t' tīna-n* (*t'* instead of *sh*).

The earliest history of the Tamil' country is still involved in obscurity. From evidence afforded by the language, Dr. Caldwell has drawn a sketch which would tend to show that the un-Aryanized Tamil'ians had "kings," who dwelt in "fortified houses," and ruled over small "districts of country;" that they had "minstrels," who recited songs at festivals; but that they were without "hereditary priests," without idols," and ideas of "heaven, hell, soul, or sin;" yet that they acknowledged the existence of God, whom they styled *kō,* or king, and erected to his honor a temple which they called *kō-il,* or God's house. Their chief worship, however, seems to have consisted in bloody sacrifices which they offered to "the devil." Dr. Caldwell further shows that they were acquainted with the ordinary metals, except tin and zinc, and with the planets known to the ancients, except Mercury and Saturn; that they had medicines, hamlets, towns, ships, and practiced the necessary arts of life, such as cotton-weaving and dyeing, though none of the arts of the higher class, as painting, sculpture, etc.; that they knew no astronomy, and were ignorant of philosophy and grammar. The earliest civilization of the Tamil'ians is traditionally attributed to the influence of successive colonies of Brahmans from upper India; and the leader of the first colony is said to have been the Rishi (q.v.) or saint *Agastya,* a personage who plays an important part in Brahmanical legends. He is called the first king of the Pāndiya kingdom, which was situated near the southern extremity of the peninsula; and by the majority of orthodox Hindus he is believed to be still alive, though invisible to ordinary eyes. His era is supposed to belong to the 6th c. B.C.; though, like all other ancient Hindu dates, this date, too, cannot be fixed with any degree of certainty. Whether the Vedic worship (see VEDA) was ever known in the Tamil' country may be matter of doubt; the worship introduced by the Brahmans seems, on the contrary, to have been that based on the incarnations of Vishn'u (q.v.) and S'iva (q.v.), and therefore to belong to an advanced stage of Hinduism. Vaishnavas, Saivas, and Śāktas (see INDIA) are the now prevalent sects of the Tamil' country; for the Jains (q.v.), who flourished in the Pāndiya kingdom, probably from the 8th or 9th c. to the 12th or 13th after Christ, were finally expelled from it; and only a few adherents of this sect may now be met with there.

The oldest Tamil works are, however, those written, or claimed to have been written, by the Jains; and it is a remarkable fact that at any period of Tamil' literature few Brahmans have contributed anything to it that may be deemed worthy of preservation. The finest composition which Tamil' possesses is the *KuRūl* of Tiruvalluvar, "a work consisting of 1330 distichs or poetical aphorisms, on almost every subject connected with morals and political economy." Dr. Caldwell holds that it is not later than the 9th c. after Christ. A commentary on this work by Parimelāgar is the most classical production which has been written in Tamil' by a Brahman. Besides the *KuRūl*, the following works are said to have received the sanction of the Madras college, which, according to tradition, founded by Vamsa Sekhara for the cultivation of the Tamil' language and literature, was then probably the most celebrated seat of learning in all Hindustan. Their names are: *Naladiyar, Nanmanikkadikai, Iniyavai Narppatu, Inna Narppatu, Kar Narppatu, Kallavali Narppatu, Lokai, Tirikadukam, Asava Kōnai, Pula Moli, Siru Pansa Mūlam, Mutu Moli Kanji,* and *Elati.* For a list of other and later works written in Tamil', both mediæval and modern, embracing the topics of religion—Protestant theology, Roman Catholic theology, Hinduism, and books published by Mohammedans—jurisprudence, philosophy, science, arts, literature, philology, geography and history, periodicals and newspapers, see the very useful *Classified Catalogue of Tamil'-printed Books, with Introductory Notices,* compiled by John Murdoch (Madras, 1865); and for learned purposes, the invaluable *Comparative Grammar of the Dravidian or South-Indian Family of Languages,* by rev. R. Caldwell (Lond. 1856).

TAMMANY, SOCIETY OF. Societies bearing this name in honor of a Delaware chief who died in the latter part of the 18th c., were about that time established in Philadelphia, New York, and other cities; but that organized in New York, May 12, 1789, was the only one that survived and still exists. This society, originally charitable, became diverted to political uses; and, in the hands of the democratic party, grew to be the recognized head of that organization, and to occupy a position in local elections which, ultimately, became apparently impregnable. The connection of many of its members with the "Tweed ring" scandal brought it into disrepute, though it regained much of its former power as the memory of that incident died away. The political struggle of 1880 again sapped its strength.

The Tammany society made its headquarters for many years in a building which occupied the site of the New York *Sun* building on Park row. It eventually erected its present building in East Fourteenth street, where its meetings take place in a commodious public hall, a smaller room in the structure being used as a German theater. The society has a committee in every assembly district in the city, and a central committee, numbering more than 1000 members. The latter committee controls the nominations, and, to a large extent, the party-vote in the city, and, to some degree, throughout the state.

TAMMERFORS, a t. in the s. of Finland, 250 m. (direct line) w.n.w. of St. Petersburg. It is situated on a rapid which connects two lakes, and affords motive-power to an extensive cotton mill employing a large number of hands. There is also a large flax mill, a fine stocking manufactory, and a paper mill. Pop. '67, 5,538.

TAMMUZ, a word which occurs once in the Bible—viz., Ezek. viii. 14: "And behold, there sat women weeping for Tammuz." The derivation of the word is as problematic as is the meaning itself. The Vulgate (all the other versions give the word unchanged—thereby confessing the universal ignorance on the subject) has Adonis, and this has indeed been accepted as the most credible explanation of this strange name. It probably means the Phenician god Adonis, whose chief temple and worship was at Byblus, but who at an early period had been introduced into Syria, Cyprus, and Greece, where he was connected with Aphrodite. His festivals were partly the expressions of joy, partly of mourning. In the latter the women gave themselves up to the most unmitigated grief over the "lost Adonis," shaved off their hair, and sacrificed their chastity in his temples. The days of mourning were completed by a solemn burial of an image of the god. This period was followed by a succession of festive and joyful days, in honor of the resurrection of Adonis. The river Adonis (Nahr Ibrahim) (see PHENICIA), which once a year "ran purple to the sea" from the Lebanon, was supposed to be tinged by the blood of the god; and a vessel sent off from Alexandria, and carried by the tide to Byblus, used to inform the mourners by letter that he had been found again. There is no doubt that the different phases of the year, or rather the disappearance and reappearance of the enlivening rays of the sun, and their influence upon all nature (see OSIRIS), were symbolized in these originally poetical, afterward licentious and fanatical rites. The time of the year at which these feasts were celebrated has given rise to much dispute. Most probably, they took place at the summer solstice; and the designation of a Hebrew month as Thamuz—which falls about our August—seems further to favor this opinion.

TAMMY, a thin worsted stuff, highly glazed. It is much used for ladies' boots, under the name of *lasting*; it is also called *durant*. It is also used, undyed, to form sieves for use in cooking to strain sauces. Such sieves are called tamnies, or tamis.

TAMP, TAMPING. See MINES and BLASTING.

TAMPA BAY, on the w. coast of Florida; an inlet from the gulf of Mexico; 40 m. long, and varying from 6 to 15 m. in width, the n. part being divided into old Tampa and Hillboro' bays. Its entrance is protected by a line of keys, or low islands, and it forms an excellent harbor. It contains a number of small islands, and fish and turtle in great abundance.

TAMPAN, a tick (q.v.) of s. Africa, remarkable for its very poisonous bite, found in Angola and the country southward from it, and described by Livingstone in his *Travels*. It attacks by preference the parts between the fingers or toes. It attains the size of a pen, and when it has satiated itself with blood, is of a dark-blue color, and its skin so tough, that it cannot be burst by squeezing with the fingers. The first effect of the bite is a mingled sensation of pain and itching, which ascends the limb until it reaches the abdomen, and soon causes either violent vomiting and purging, or fever. The tingling sensation lasts for a week.

TAMPI CO. or Santa Anna de Tamaulipas, a sea-port of Mexico, in the state of Tamaulipas, on the Panuco, 5 m. from its mouth in the gulf of Mexico. Its streets are broad and regular, and among other institutions it contains a custom-house. At the mouth of the river is a dangerous bar, and the harbor is unsafe. Hides, tallow, bones, and salted meat are exported to Great Britain and the United States. The annual imports amount to about £668,000; the exports—greatly reduced within recent years by the state of anarchy and confusion into which the country has been plunged—to £235,000.

TAMPION, the wooden plug placed in the mouth of a piece of ordnance to preserve it from dust and damp.—In naval gunnery the tampion is the wooden bottom for a charge of grape-shot.

TAM-TAM, an Indian musical instrument, resembling the tamborine (q.v.), but larger and more powerful, and oval instead of round. It has been occasionally introduced into orchestral bands.

TAMUS. See BRYONY.

TAMWORTH, a parliamentary and municipal borough, partly in the county of Stafford, partly in that of Warwick, at the confluence of the Tame and Auker, 7 m. s.e. of Lichfield. Of the ancient church, the transepts are Norman; the remains of the ancient castle, to which modern additions have been made, are in various styles. Brickmaking, brewing, dyeing, wool-stapling, and manufactures of tapes and small wares are carried

on. There is a bronze statue to the late sir Robert Peel, erected in 1852. Pop: '71 of municipal borough, 4,589; of parliamentary borough, 11,493.

TAN'AGER. *Tanagra*, a genus of birds of the finch family *fringillidae*, having a conical beak, triangular at the base; the upper mandible notched toward the tip, and its ridge arched. The species are numerous, and the Linnæan genus has been divided into a number of genera, all of which possess the characters just given, and popularly receive the name tanager. All of them are American, and most of them belong to warm regions; but some visit more northern parts of America as birds of passage. Many of the tanagers are birds of very beautiful plumage, and many have good powers of song. The **ORGANIST TANAGER** (*T. or euphonia musica*) is particularly famous for its rich full tones.

TANAKA FUJIMARO, b. in the province of Owari, Japan, about 1843. During the revolution of 1868 was one of the leaders in the cause of progress. He was made vice-minister of education in 1871, and visited America and Europe on an educational mission. On his return to Japan he zealously devoted himself to perfecting a plan of national education by which nearly 3,000,000 Japanese youth of both sexes now attend public-school. In 1876 he again visited the United States to observe the system of education, representing Japan's educational progress at the Centennial exposition. On his return to Japan he established in Tokio a museum of education to which American schools and educators largely contributed. In 1879 he was made minister of justice.

TANANARIVA'. See **ANTANANARIVA**.

TAN-BALLS. A useful way of utilizing the spent bark of the tanner's yard has been adopted in many parts of England: it consists in pressing the bark into balls or lumps, which harden on drying, and serve for fuel.

TANCRED, a Sicilian prince, the son of Eudes, a Norman baron, and of Emma, the sister of Robert Guiscard (see **GUISCARD**), was one of the celebrated heroes of the first crusade, and was born after the middle of the 11th c. A.D. Some chroniclers profess to detail the events of his early life, describing him as the most accomplished youth of his time in athletic and military exercises, and of a wisdom far surpassing that of men of mature years, and as a partisan of his cousin Bohemond (q.v.) in the quarrel with their uncle, Roger (q.v.) of Sicily. But the first authentic information respecting him is that he raised a large body of men in Apulia and Calabria, and joined Bohemond, then on his way to the first crusade. The two cousins landed in Epirus, and first one and then the other made their submissions to the Greek emperor, Alexis. Tancred's exploits on the way to Syria; his quarrel with Baldwin for the possession of Tarsus, and his subsequent chivalrous forbearance to, and rescue of, his rival; his wondrous valor before Antioch, where he killed no fewer than 760 infidels, transmitting the heads of 70 to the pope, and received a corresponding number of marks of silver in return; his vigorous repulse of the first sortie by the infidels from Jerusalem; his sad and lonely vigil on the mount of Olives; and his gallantry at the storming of the sacred city, are all detailed by the numerous chroniclers of this epoch, in their usual style of extravagant laudation, but with a harmony which speaks favorably for their correct appreciation of his character. He was one of the claimants of the throne of Jerusalem, and was pacified by Godfrey (q.v.), the successful competitor, with the gift of some towns in Palestine, and the principality of Galilee or Tiberias. A brief quarrel with Baldwin, after Godfrey's death, petty combats with the infidels, and occasional wars with the other Christian princes who had settled in Syria and Palestine, occupied the remainder of his life, which was brought to a close at Antioch in 1112. Besides his own principality, he governed that of Antioch, belonging to his cousin Bohemond, from 1100. The fiery and energetic, but at the same time pious, sagacious, and forbearing chief whom the chroniclers present to us has been considerably toned down by Tasso in his *Gerusalemme Liberata*.

TANEY, a co. in s. Missouri, adjoining Arkansas; drained by White river and several creeks; 750 sq.m.; pop. '80, 5,633—5,614 of American birth, 4 colored. The surface is rough, heavily wooded, and moderately fertile; corn, wheat, hay, and pork are the products. Copper and lead are found. Co. seat, Forsyth.

TANEY, ROGER BROOKE, LL.D., 1777—1864; b. Md.; graduated at Dickinson college, Penn., 1795; studied law, and in 1799 was admitted to the bar. He practiced in Calvert co. and Frederick, removing to Baltimore in 1822. He was attorney-general of the state in 1827, and in 1831 president Jackson made him attorney-general of the United States. Two years later he was nominated to succeed Duane as secretary of the treasury, but on account of his opposition to the U. S. bank the appointment was not confirmed by the senate. The senate also refused, 1835, to confirm his appointment to the supreme court bench, but two years later he succeeded chief-justice Marshall and ably sustained the high reputation for legal profundity and acumen which the supreme court had gained under his immediate predecessor, though the events of the war have overthrown many of the positions then taken. Many most important decisions on constitutional questions were given by him, the most noted being that in the "Dred Scott" case (q.v.). This decision, with the accompanying expression of opinion, had much to do with the discussions and animosity which resulted in war. When in the spring of 1861 application was made to Taney for a writ of *habeas corpus* in the case of a Baltimore citizen who had been arrested by a U. S. officer on a charge of treason, he at once granted it,

denying the right of the president to suspend the *habeas corpus* act. A memoir of Tancy's life, in part an autobiography, was published, 1872, by prof. Samuel Tyler. A bronze statue of him, executed by Rhinehart for the state of Maryland, stands in the city of Annapolis.

TANGANYIKA, a lake of eastern central Africa, lying between lat. 3° and 8° 45' s. Long. of center, 30° e.; surface, 2,710 feet above the sea; length, 350 m.; breadth, from 15 to 60 miles. It was discovered by Speke and Burton in 1858. In 1871 Livingstone confirmed Burton's conclusion, that the Rusi Zi flows into its n. extremity. Cameron surveyed the s. and w. coasts in 1874, and discovered an outlet, the Lukuga, on the w. side. In 1876 Stanley satisfied himself that this channel, which he proved to communicate with the Luabala or upper Congo, is generally dried up in certain parts of its course, and only carries the overflow of Tanganyika westward at intervals of years.

TANGENT. See TRIGONOMETRY.

TANGHIN. *Tunghinia venenifera*, or *cerbera tanghin*, a tree of the natural order *apocynaceæ*, a native of Madagascar. The fruit is a drupe, of which the kernel is so deadly a poison, that although not larger than an almond, one kernel is sufficient to destroy twenty people. It was used in Madagascar as an ordeal for the discovery of guilt or innocence, and with the general result of the death of those subjected to it. A little of the powdered kernel was placed on the tongue of the suspected person, and he was obliged to swallow it. Only those recovered whose stomachs quickly rejected the dose. The progress of Christianity and civilization in Madagascar has led to a discontinuance of the use of this ordeal. A similar poison-ordeal is used in some parts of Africa. See ORDEAL and ERYTHROPHLEUM.

TANGIER, a sea-port of Morocco, on a small bay or inlet of the strait of Gibraltar. 38 m. s.w. of the town of that name. It is a small, ill-built town, situated on two hills; the houses—with the exception of the residences of foreign officials—being, as a rule, miserable edifices, and the streets being narrow and dirty. The town is surrounded by old walls and protected by several forts. It has an extensive shipping trade—the annual value of the entering and clearing cargoes being, according to recent accounts, above £600,000. Tangier was taken by the Portuguese in 1471, ceded to the English in 1662, and held by them for 22 years. Pop. about 9,500.

TANGIPAHOA, a co. in s.e. Louisiana; bounded on the n. by Mississippi, on the s. by lakes Pontchartrain and Maurepas; drained by the Tangipahoa river; traversed by the Chicago, St. Louis and New Orleans railroad; about 725 sq.m.; pop. '80, 9,635, 4,035 colored. The surface is flat. The soil is sandy but fertile in some parts. The principal productions are corn, rice, potatoes, and cotton. Co. seat, Amite City.

TANGLE, the common name of *laminaria digitata* and *l. saccharina*, two species of sea-weed, natives of the British shores, growing on rocks in deep water. The stem is woody, the frond leathery, flat, and without a midrib. The woody stems are sometimes used for knife-handles, the blade being stuck in when the handle is soft, and held fast by its shrinking as it dries. The young stalks form an article of food and are nutritious, owing apparently to the large quantity of gelatinous matter which they secrete. They are also used for feeding cattle. *L. potatorum*, a large species, supplies the aborigines of Australia with instruments, vessels, and food.

TANIS, the Tyrian name of the goddess Astarte (q.v.).

TANISTRY, an ancient Celtic custom of succession, which is generally described as devolving the right to inherit lands or honors on the oldest and worthiest of the blood. The tanist, or righdomna, was the heir-apparent of the monarchy, whom it was the practice to appoint during the lifetime of the sovereign; and there is no doubt that the nearest to the original stock was held to have a preferable claim, as contended by Bruce in his claim to the Scottish throne. The practice of electing a successor was also applied to the inheritance of land, and to succession to ecclesiastical offices.

TANJUR, more commonly written TANJORE, an important town of India, in the presidency of Madras, 180 m. s.s.w. of the city of that name, in the midst of an extensive plain, on one of the branches of the delta of the Kaveri. The town comprises two forts and several suburbs. The former are so connected that they may almost be regarded as one. The smaller of the two is a parallelogram in shape, and 600 yards in extreme length. It is joined on the north to the larger fort, which is circular in shape, and 1100 yards in greatest diameter. The walls of both are lofty and strong, and are surrounded by a ditch cut out of the solid stone. The principal edifices of Tanjur are the great pagoda, esteemed the finest specimen of a pyramidal temple in Hindustan (see INDIAN ARCHITECTURE), and the palace of the rajah. Silks, muslins, and cottons are manufactured. Pop. '71, 52,175. The province of Tanjur, of which the town of the same name is capital, has an area of 3,735 sq.m., and contained, in 1871, 1,975,042 inhabitants.

TANK-WORMS. The mud in Indian tanks has been found to abound in *filaria*, some of which closely resemble the guinea-worm infesting the human body. Although there is no positive evidence, there is extreme probability that these tank-worms are the origin

of the guinea-worm. Dr. Carter, who has had much personal observation of the guinea-worm in India, "argues, and apparently with good reason, *no tank-worm, no guinea-worm*. Persons who bathe in water in which the former is found may expect to have the latter." Mr. Bastian, who has written an excellent paper on the anatomy of the guinea-worm, states that there is an undoubted anatomical relation between it and the tank-worm. The real difficulty in the theory is that these tank-worms are widely diffused, while the guinea-worm is restricted in its localization.

TANNAHILL, ROBERT, was b. on June 3, 1774, at Paisley, where his life was almost entirely passed in the humble occupation of a weaver. Very early he exhibited a taste for poetry, and out of his constant study of the works of Burns, Ferguson, and Ramsay, the ambition was developed in him of emulating these favorite authors. His poetry soon became known, and procured him a local celebrity, which on the publication, in 1807, of a collection of his pieces (*Poems and Songs*; new and larger ed., with a memoir of the author, Glasgow, 1838), was ratified by a wider acceptance. But while his modest fame was extending itself, his life had an abrupt termination. He was found one morning (May 17, 1810) drowned in a canal near Paisley; and there seems almost no reason to doubt that his death was that of the suicide. A morbid melancholy which seems to have been inherent in his nature had gradually been growing upon him, and clouding his life with hopeless gloom. He died at the age of 36.

As a song-writer, Tannahill continues to be remembered; and some few of his best pieces have established themselves as part of the musical repertory of the Scottish people. He has a genuine lyrical gift, much tenderness of sentiment, and a true eye and feeling for the simple effects of nature with which he was familiar. Of the force and passion of Burns, he has nothing; but in grace and sweetness, Burns himself has scarcely perhaps surpassed certain of his happier passages.

TANNHÄUSER, the subject of one of the most attractive German legends of the middle ages, is a knight who, in the course of his travels, comes to Venusberg (q.v.), and enters the cave-palace, to behold the wonders of the lady Venus and her court. After having lived there for some time in every kind of delight, his conscience smites him. Invoking the Virgin Mary, he obtains leave of absence, and makes a pilgrimage to Rome, to pope Urban, to seek, through confession and penance, remission of his sins, and escape from damnation. But the pope, who happens to have a wand in his hand, tells him that he can as little obtain God's mercy as that dry wand can become green again. Thereupon Tannhäuser departs in despair, and returns to the lady Venus in the mountain. Three days afterward, however, the wand begins to sprout and bear green leaves; and the pope immediately sends out messengers to every country, but in vain—Tannhäuser can nowhere be found. Such is the story as told in the popular ballad once common all over Germany, and even beyond it, and sung in the district of Entlibuch as late as the year 1830—the best version of which is in Uhland's *Alte hoch- und niederdeutschen Volkslieder* (Stuttgart, 1845). In the preface of the *Heldenbuch*, it is further added, that "the faithful Eckhart"—a character in German heroic legends—sits before the mountain, and warns the people of its dangers. In this shape, the story may be traced as far back as the 14th c.; but the substance of the legend is much older, and goes back to the days of German paganism. Some traditions connect it with the Hoeselberg or Hörselberg, near Eisenach, in which the lady Holle or Holda (see BERCHTA) held her court, who, on her part again, seems to be identical with Freyja, the Scandinavian Venus. The peculiar mythological meaning of the saga, which has numerous points of contact with many other German traditions, has, however, never yet been thoroughly inquired into. Grimm sees in it a touching portrayal of the regret that lingered in the popular heart after the departing paganism, and of the sternness of the Christian priesthood in regard to it. Compare Kornmann, *Mons Veneris* (Fkf. 1614); Grässe, *Die Sage vom Ritter Tannhäuser* (Dres. and Leip. 1846). In later times, the saga has been put into poetical form, among others by Tieck, and made use of by R. Wagner in an opera. This idea of subterranean palaces in which the king or queen of dwarfs, pigmies, fairies, and so forth, held their court, seems to have been universal. Everywhere, stories are told of men being enticed to enter, and finding it difficult or altogether impossible ever again to obtain their liberty. See RHYMER, THOMAS. The visit of Ulysses to the isle of Calypso, and that of Circe, appear to be only modifications of the same idea.

About the middle of the 13th c., and contemporary with pope Urban IV., 1261-65), there lived in reality in Germany a Bavarian knight named Tannhäuser, who, as Neidhart relates, after returning from the wars, resided as minnesinger (q.v.) at the court of the Austrian duke Frederick II. the quarrelsome. At the duke's death, and after having wasted his substance in dissipation, he resided partly with duke Otto II. of Bavaria, and partly led a wandering life. Tannhäuser has composed fine spirited ballads, which, however, show the decay that had already set in in the minnesinger's art. Tannhäuser's memory was held in high regard by the meistersingers, who also preserved one of his measures; and it is quite possible that this Tannhäuser may have been introduced into popular fiction, and have had his name worked into a myth, in which there is some resemblance to his actual fortunes; in which process, however, that old myth became transformed into the more modern saga. The poems of Tannhäuser are published partly in the second part of the *Minnesinger* (published by Von

der Hagen, Leip. 1828), and partly in the 6th vol. of Haupt's *Zeitschrift für Deutsches Alterthum* (Leip. 1818).

TANNIC ACID, or **TANNIN**. Under these synonymous terms, chemists include a number of solid non-nitrogenous substances, consisting of carbon, hydrogen, and oxygen, some of which are crystalline, and others amorphous, and possessing no smell, but a well-marked astringent taste. They are soluble in water and alcohol, the solutions being acid, and yielding precipitates with most metallic oxides. A solution of gelatine is also precipitated by a solution of any of the tannic acids, and the gelatinous tissue in raw hides is by an analogous process converted into leather. See **GALLOTANNIC ACID**. None of these acids are volatile; and when exposed to the action of heat, they decompose, and yield the so-called pyro-acids. The persalts of iron yield bluish-black or green precipitates with the tannic acids.

The members of this group are widely diffused throughout the vegetable kingdom. "The bark and leaves of most forest trees, such as the oak, the elm, the willow, the horse-chestnut, and the pine—and of many fruit trees, such as the pear and plum, contain tannin in notable quantity. The wood and bark of many shrubs, such as the sumach and whortleberry, and the roots of the tormentilla and bistort, are also powerfully astringent, owing to the presence of one of the forms of tannin. Coffee and tea, as well as Paraguay tea, likewise contain a modification of this principle. All these bodies, except coffee, precipitate the persalts of iron of a bluish-black color; or, if a free acid be present, the solution assumes a dark-green color."—Miller's *Organic Chemistry*, 2d ed. p. 400. The variety of tannin, or tannic acid, occurring in catechu and kino, produces a green precipitate with the persalts of iron; while that occurring in matricaria, rhatany, and the common nettle, produces a gray precipitate. The principal members of this group are—1. *Gallotannic acid*, or *tannic acid*, $C_{54}H_{42}O_{31}$ (in the ordinary acceptation of the word), which is mainly obtained from the gall-nut, and has been described in a special article; 2. *Moritanic acid*, $C_{36}H_{18}O_{20}$, obtained from fustic (*morus tinctoria*); 3. *Quinotannic acid*, $C_{22}H_{10}O_{17}$, obtained from cinchona bark; 4. *Quercitanic acid*, from oak bark; 5. *Mimotannic acid*, $C_{54}H_{42}O_{31}$, from catechu; and 6. *Kinotannic acid*, from kino; to which some chemists add a variety occurring in coffee and Paraguay tea, to which the term *caffotannic acid* is given.

TANNING. See **LEATHER**.

TANSY, *Tanacetum*, a genus of plants of the natural order *compositæ*, sub-order *corymbifere*, allied to *artemisia* (q.v.), and having hemispherical heads of flowers, with the florets all tubular, the receptacle naked, the pappus a slight membranous border. The species are pretty numerous, and are natives of the temperate parts of the old world. COMMON TANSY (*T. vulgare*) is a native of Britain and of continental Europe, growing in fields and by roadsides, river-banks, etc. It has long been generally cultivated in gardens. It is now naturalized, and pretty common in many parts of North America. It is a perennial, from two to four feet high, with great abundance of deep-green, bipinnatifid, inciso-serrate leaves; the flowers in terminal corymbs, yellow, and rather small. The leaves and flowers have a strong aromatic smell and a bitter taste. The young leaves are used for flavoring puddings, cakes, omelets, etc. The plant is also tonic and anthelmintic, and *tansy tea* is an old popular medicine. Some curious old customs still linger in many parts of England connected with the use of *tansy cakes* and *tansy puddings* at Easter, which was originally intended to represent the use of bitter herbs at the paschal feast. In some parishes of the counties of Devon and Dorset the clerk carries round to every house a few white tansy cakes as an Easter offering after divine service on Good Friday, and receives a gratuity from each householder. In former times both ecclesiastics and laics played at ball in the churches for tansy cake at Easter-tide. The highest dignitaries took part in this, and began the ball-playing, which went on during the antiphone, and was accompanied with dancing. After the ball-playing was over, all retired for refreshments; and a gammon of bacon was a standard dish, to signify abhorrence of the Jews. A tansy pudding was an essential part of the feast.—See Chambers's *Book of Days*.

TANTALUM (syml. Ta, new equiv. 182) is a very rare metal, discovered in 1802 by Ekclberg in the Swedish minerals known as tantalite and yttrotalantite. It is so closely allied to columbium or niobium that Wollaston regarded the two metals as identical, a view which was generally adopted till Rose disproved it. As it is of no practical importance, it is unnecessary to enter into any details regarding it.

TANTALUS, a genus of birds of the family *ardidae*, resembling storks in their feet and bill, except that the ridge of the bill is rounded, and its tip gradually curved downward, and slightly notched on each side; a portion of the head, and sometimes of the neck, is bare. The AFRICAN TANTALUS (*T. ibis*) was long regarded as the *ibis* (q.v.) of the ancient Egyptians, but it is rare in Egypt, and belongs chiefly to Senegal. It is much larger than the true *ibis*. The AMERICAN TANTALUS, or WOOD IBIS (*T. locustator*), is as large as a stork, but more slender, white, with black quill and tail feathers, the naked skin of the head and neck black. It is found both in North and in South America. In the United States it chiefly inhabits the swampy districts of the south.

TANTALUS, a character noted in Greek mythology for the punishment he suffered in the lower world. He is said to have been the son of Zeus by Pluto, and some accounts describe him as king of Argos or Corinth. Various reasons are assigned for his undergoing the severe punishment which he did, the most common being that he divulged the divine counsels of Zeus, which the latter had communicated to him as secrets. In the lower world he was afflicted with an insatiable thirst, and had to stand up to the chin in a lake, the waters of which receded whenever he tried to drink of them. Clusters of fruit hung over his head, which eluded his grasp whenever he endeavored to reach them, his mind at the same time being kept in a state of constant terror lest a huge rock, suspended above his head, and ever threatening to fall, should crush him. Tantalus, or rather the punishment which he suffered, has supplied the English language with the very significant verb, "tantalize." Tantalus was the father of Pelops, Broctas, and Niobe.

TANTRA (from the Sanskrit *tan*, to believe, to have faith in; hence, literally, an instrument or means of faith) is a name of the sacred works of the worshippers of the female energy of the god Śiva. See ŚĀKTAS. A Tantra is said to comprise five subjects—the creation and destruction of the world, the worship of the gods, the attainment of all objects, magical rites for the acquirement of six superhuman faculties, and four modes of union with spirit by meditation. A variety of other subjects, however, are introduced into many of them, while some are limited to a single topic, as the mode of breathing in certain rites, the language of birds, beasts, etc. They always assume the form of a dialogue between Śiva and his wife, in one of her many forms, but mostly as *Umā*, or *Pārvatī* (q.v.), in which the goddess questions the god as to the mode of performing various ceremonies, and the *mantras*, or prayers and incantations to be used in them. These he explains at length, and under solemn cautions that they involve a great mystery, on no account whatever to be divulged to the profane. The efficacy of these *mantras* is deemed to be all-powerful, and, according to some Tantras, that of the faith in these revelations of Śiva so great, as to free a believer from the consequences of even the most atrocious sins. The followers of the Tantras profess to consider them as a fifth Veda (q.v.), and attribute to them equal antiquity and superior authority. Though such an antiquity, or even one approaching the age of the four Vedas, is entirely imaginary, the question of their date is nevertheless involved in obscurity. As Tantras are referred to in some of the *Purāṇas* (q.v.), they must have preceded these; but as, on the one hand, the age of the *Purāṇas* themselves is merely conjectural, and as there probably existed older *Purāṇas* than those we possess now; and, on the other hand, as there might likewise have been older Tantras, from which the works now so called were compiled, the circumstance that Tantras are quoted by some *Purāṇas* would not throw much light on the date of those now extant. It seems more significant, however, that the oldest known author of a glossary of classical words, Amarasinha (see *lexicography*, under SANSKRIT LITERATURE), should have omitted from among the meanings he assigns to the word *tantra*, that of "a sacred book;" whereas the later commentators on his work do not fail to supply this omission, which certainly would have been an extraordinary one had Tantras existed at the time of Amarasinha. If, then, this negative evidence has the value which it seems to have, the Tantras would, at all events, be later than the first centuries of the Christian era. The works of this class are very numerous, and it is to be regretted that Sanskrit philology, which has already investigated, more or less profoundly, nearly all the branches of Sanskrit literature, should hitherto have almost entirely neglected this particular branch of it. The principal Tantras are the *Syāmārahasya*, *Rudrayāmala*, *Mantramahodadhī*, *Sāradādhika*, and *Kālīkānta*.—See H. H. Wilson, *A Sketch of the Religious Sects of the Hindus*, Works, vol. i., edited by Dr. Rost (London, 1862).

TANTUM ERGO, the hymn uniformly sung in the Roman Catholic church at benediction with the holy sacrament. These are the first words of the penultimate strophe of the hymn *Pange Lingua*. The *Tantum Ergo* is the most popular of all the eucharistic hymns of the Roman Catholic church.

TANZIMAT, or **TANSMAT**, the plural of the Arab word *tanzim*, generally signifies "regulations," but in a special sense denotes the organic laws established by the Hattı-Sherif of Gulhane, in accordance with which the administration of the Turkish empire is carried on. These organic laws, the first attempt at constitutional government in Turkey, were published by Sultan Abdul-Medjid in 1844, and treat of—1st, the political organization of the empire, and the powers and jurisdiction of the chief officials and higher courts; 2d, administration and finance; 3d, justice; 4th, military affairs. But the tanzimat was a dead letter, or nearly so, except in connection with the army; so that on Sept. 7, 1854, the sultan found it necessary to publish a new ordinance, in which the complete carrying out of the tanzimat in all respects was commanded; and a commission was appointed to see that this was done.

TAORMINA (anc. *Taurromenium*), a t. on the e. coast of Sicily, province of Messina, situated on a narrow ledge of rock, 900 ft. above the sea, about 30 m. s.w. of Messina. It consists mainly of a single street, more than a mile in length, is surrounded by a Saracenic wall, has numerous convents and churches, many picturesque palaces and mansions built in the middle ages, and numerous relics of antiquity, among

which are very fine supulchers, an aqueduct, tessellated pavements, remains of a "Nau-machia" and of a theater, the last reckoned one of the most splendid ruins in Sicily, and commanding a view of almost unparalleled magnificence. Taormina has some trade in wine and hemp, and a pop. '72 of 2,004.

Ancient *Tauromenium* was built after the destruction of Sicilian Naxos in 403 B.C., but the exact date is uncertain. It rapidly attained prosperity; but its history during the Greek and Roman period presents no striking features.

TAOS, a co. in extreme n.w. New Mexico, adjoining Colorado; drained by the Rio Grande and Rio de Chaco rivers; 7,500 sq. m.; pop. '70, 12,079. The surface is crossed by the Sierra San Juan and other mountain ranges, and comprises the southern part of what is known as the San Luis park; wheat, corn, pork, and wool are the staples. Co. seat, Fernandez de Taos.

TAPAJOS, an important river of Brazil, and an affluent of the Amazon, is formed by confluence of the Arinos and the Juruena, both of which rise in the south of the province of Matto Grosso. After a northward course of upward of 1100 m. in length the Tapajos falls into the Amazon, about 20 m. below the town of Santarem. In lat. about 7°30' s., it has a fall of 30 ft.; but the interruptions to the navigation, which is said to reach to within a short distance of the source of the river, are few. A portage of only 18 m. separates the upper waters of the Tapajos from those of the Paraguay.

TAPESTRY (Fr. *tapisserie*), a kind of carpet-work for decorating walls and furniture. The art of working tapestry is extremely ancient, but we have little information about it until the time of the Saracens, who revived it, and brought it into notice. They, in all probability, only used tapestry as drapery or curtains for the courts of their houses; its use as a covering for walls seems to have been an invention of the Flemings previous to 1606, at which date it was introduced into France by Henry IV., who engaged Flemish artists to teach it. At that period, so generally was its origin attributed to the Saracens that it was called *Sarrasinis*. The oldest piece in existence is that described under the name of the BAYEUX TAPESTRY (q.v.). At first, the Saracenic tapestries were only ornamented with flowers and geometric figures; but the Flemings aimed higher, and sought to enrich them with historic subjects of the highest order; and so important did this art become, that the most eminent masters in painting, from Raphael downward bestowed their greatest efforts upon cartoons to serve as copies for the tapestry-workers, of which the celebrated Raphael cartoons, formerly at Hampton Court, now in a gallery especially designed for them in the Kensington museum, are illustrations (see CARTOON). After its first introduction into France by Henry IV. at the beginning of the 17 century, the art of making tapestry does not appear to have made much progress until the middle of that century, when a small establishment founded by the brothers Canaye on the premises formerly occupied by Jean Gobelins, a dyer of wool, was commenced, and was afterward carried on by a Dutchman named Gluck and his assistants with such success, that it was suggested by Colbert, the minister of Louis XIV., that it should be taken under the king's patronage; in consequence of which the establishment was bought, and constituted a royal manufactory in 1667, under the management of M. Lebrun, who was the first director. A royal carpet-manufactory had been previously established in 1615; this was called La Savonnerie, from the previous use of the buildings for the manufacture of soap. The Savonnerie and the Gobelins were both carried on with great spirit by successive sovereigns, and were formed into one establishment in 1826, when the works of the Savonnerie were removed to the Gobelins, where this most interesting work is now carried to great perfection, and also at a minor establishment at Beauvais, in the department of Oise, where it is, however, worked in a different style and manner. At the Gobelins, a series of threads are arranged vertically in a frame like the warp of a loom, and the workman stands behind the frame, the pattern being placed behind him for reference. To produce the design, he has a number of wooden needles threaded with wool and silk of the colors required, and these are passed through the upright warp-threads, and brought back, so that each thread becomes covered with the necessary color; and such is the extreme nicety with which this is done, and such the delicacy and multiplicity of the shades of color employed, that but little difference can be detected between the tapestry picture and the painting from which it was copied. At Beauvais, the warp is placed horizontally, and the workman stands over it; this renders it necessary to cut off the ends on the upper surface, which is avoided in the other plan of working from behind. The Beauvais is, however, a style intermediate between tapestry and carpet-work, and the roughness of surface so produced has a good effect. Much fine tapestry was employed in former times in decorating the palaces and mansions of Great Britain, in many of which it is still seen in great beauty. The modern works of the Gobelins were distributed as presents by the late imperial government of France. They are not produced in great numbers, and are of great money value. The number of artists employed is about 120.

TAPEWORM is a word popularly used in a vague sense to designate any worm of the group *cestoidæ* (see CESTOID WORMS). According to Dr. Cobbold, upward of 250 distinct forms of cestoid worms have been described, of which probably somewhat less than 200 may be regarded as really good species. These he divides into the three families of (1) *teniadae*, or true tapeworms; (2) *bothriocephalida*, and (3) *tetrarhynchida*. For the natural

history of the tapeworms generally, we must refer to the article **CESTOID WORMS**. We will here only remind the reader of the following points necessary for the due understanding of this article, and that every tapeworm passes through several distinct phases during its life-history. "In the ordinary colonial or tapeworm condition," says Dr. Cobbold, "it has been termed the *strobila* (Van Beneden). The separate joints of which the strobila is composed are denominated *proglottides*, or *zooids*. The anterior segment forms the *head*, and remains barren, those of the neck and front part of the body being sexually immature during the process of strobile-formation. The mature proglottides at the caudal end are capable of realizing an independent existence, and the eggs which they contain develop the six-hooked embryos, or *proscolices* (Van Beneden), in their interior. These latter become metamorphosed into *scolices* or *nurses*, representing the well-known cysticercal state, which, in its sterile or aborted condition, forms the common *hydatid*."—*Entozoa*, p. 105. During the greater part of their existence, the tapeworms are parasitic animals, the mature proglottides and eggs being free only during a comparatively short interval. They are mostly restricted in their distribution to the vertebrate animals, comparatively few of the invertebrates (excepting the cuttle-fish) appearing to harbor them in their adult condition, although the tapeworm larvæ, nurses, or *scolices* probably abound in various invertebrate groups. In the human body, no less than ten species of tapeworm occur, viz., eight *true tapeworms*, and two species of *bothriocephalus*; and as four distinct species have been found in the Barbary ape, it is obvious that errors of diet, due to civilization, are not the cause of these parasites. Among the animals with which we are most familiar, the species are plentiful in the common dog (and in true carnivora generally), in rats, and mice. The typical ruminants are almost constantly invested both by mature and immature forms; while the larger pachyderms, and solidungulates (the horse, ass, etc.), harbor only a few adult forms; but only larvæ appear to be known in swine. These worms appear to be as abundant in granivorous birds as in carnivorous hawks, owls, etc. In the water-birds generally, the adult worms are very abundant, their larvæ existing in the food of such birds, in fishes, mollusks, etc. In reptiles, these worms are extremely rare, although other parasitic worms abound; while in fishes they are very abundant both in the adult and larval forms.

The *teniada*, or *true tapeworms*, may be distinguished from the other families of the order *cestoidea* (cestoids or tapeworms in the popular sense) "by the possession of a small distinct head, furnished with four simple oval or round suckorial disks (suckers), and commonly also with a more or less strongly pronounced rostellum (proboscis) placed at the summit in the median line. This prominence, when largely developed, becomes retractile, and when not in use, is lodged within a flask-shaped cavity, lined by a sheath, and supplied with special muscles; it is also very frequently armed with a single or double crown of horny chitinous hooks, there being occasionally as many as five or six separate circular rows of these organs. Attention to the number, relative size, and disposition of the hooks is often sufficient to determine the particular species. In nearly all cases the reproductive orifices are situated at or near the margins of the joints which are bisexual."—Cobbold, *op. cit.*, p. 109. The eight true tapeworms occurring in man are—

- (1) *Tenia solium*, Linneus; (2) *T. mediocanaliculata*, Küchenmeister; (3) *T. acanthotriax*, Weinland; (4) *T. flavopunctata*, Weinland; (5) *T. nana*, Von Siebold; (6) *T. elliptica*, Batsch; (7) *T. marginata*, Batsch; (8) *T. echinococcus*, Von Siebold.

The common tapeworm, *tenia solium*, derives its Linnean title from the idea that it is always a solitary worm. Although this is commonly, it is not by any means always the case; Küchenmeister has several times found two or three together, and cases are recorded in which 30 and even 40 worms have been expelled from one patient. The full-grown tapeworm (strobila) has been known from the earliest times, and is described by Hippocrates, Aristotle, and Pliny; but its organization and mode of development have only been properly understood during the last few years. The segments of which it is composed vary in size, and number from 800 to 1000, the earlier immature ones being extremely narrow, and the sexually mature joints commencing at about the 450th segment. From 10 to 35 ft. may be regarded as representing its ordinary length; its breadth at about the widest part being one-third of an inch. The head, which is seldom seen in the tapeworms exhibited in our museums, although the evacuation of the head with the rest of the worm is not very rare, is very small and globular (about the size of a pin's head), with black pigment ingrained in it. On examining it with a low magnifying power, it displays four circular sucking disks, in front of which is a conical proboscis, armed with a double crown of hooks, from 22 to 28 in each circular row. The head is succeeded by a very narrow neck, nearly half an inch in length, which is continued into the anterior or sexually immature part of the body, in which traces of segmentation first appear in the form of fine transverse lines, which are gradually replaced by visible joints. These joints or segments represent the body, and each mature segment contains both male and female organs of generation; and in addition to these structures, the entire series of joints is traversed by a set of vascular canals constituting the so-called aquiferous system, which consists of two main channels, one passing down on either side of the worm, and both being connected by transverse vessels, which occur singly at one end of every joint. It is only in the alimentary canal of man or some other animal that a tapeworm of any kind can attain to sexual maturity; and in all of these the eggs are fecundated before being discharged. The expulsion of the eggs may take place in any of

the following ways: First, the mature segments separate from each other, and passing out of the body, either with the ordinary evacuation of the bowels or independently, become decomposed, and set free the enclosed eggs. The single joints thus discharged undergo violent contraction after being expelled, which led to their being formerly mistaken for a distinct species of worm, to which the title *vermes cucurbitini* was applied, from their resemblance to a pumpkin seed. There is a figure in Aitken's *Medicine*, 3d ed. vol. i. p. 815, showing the joints of a *tenia mediocinellata* (which will be presently described) of the natural size, in various stages of contraction; and on examining the recently discharged excrement of a constipated dog, the same phenomenon may be very frequently observed. Secondly, the eggs may be discharged through the genital pore by pressure from any cause. It is only thus that we can account for the occasional (but very rare) coexistence of a *cysticercus cellulosæ* (the embryo of the worm) and an adult tapeworm in the intestinal canal of the human subject—an association which constitutes one of the most serious dangers which the matured worm can inflict upon its host, and one of the strongest indications for its removal. Thirdly and lastly, the mature joints sometimes appear to undergo disintegration within the intestine, and to liberate the eggs; but the conditions under which this disintegration occurs are unknown. In reference to the ultimate fate of the embryos *in ovo*, that are liberated in the intestinal canal, Dr. Cobbold has informed the author of this article in a private communication, that, in his opinion, they do not migrate in the living host, except when by regurgitation they occasionally get into the stomach, when, after their shells have been dissolved by the gastric juice, the young organisms commence their wanderings. The mature segments are usually expelled from the human bowel at the rate of six or eight a day. Their vitality is prolonged by moisture, which favors the distribution of the liberated eggs over grass and other vegetables, or in water, which may be used as food or drink by animals. For a full description of the eggs we must refer to Dr. Cobbold's work. It is sufficient here to remark that, in their mature condition, they "present a globular figure, and are easily recognized by their remarkably thick shell, which surrounds the six-hooked embryo. They present an average diameter of $\frac{1}{16}$ of an inch, the shell itself measuring about $\frac{1}{100}$ of an inch in thickness. After a while, by accident as it were, a pig coming in the way of these embryos, or of the proglottides, is liable to swallow them along with matters taken in as food. The embryos, immediately on their being transferred to the digestive canal of the pig, escape from the egg-shells, and bore their way through the living tissues of the animal, and having lodged themselves in the fatty part of the flesh, they there rest to await their further transformations or destiny. The animal thus infected becomes meased, its flesh constituting the so-called measy pork. In this situation the embryos drop their hooks, and become transformed into the *cysticercus cellulosæ*. A portion of this meased meat being eaten by ourselves, either in a raw or imperfectly cooked condition, transfers the *cysticercus* to our own alimentary canal, in which locality the *cysticercus* attaches itself to the wall of the human intestine, and having secured a good anchorage, begins to grow at the lower or caudal extremity, producing numerous joints or buds to form the strobila or tapeworm colony."—Cobbold, *Entozoa*, p. 221. In its fully mature stage the *mease* presents the appearance of an elliptical hydatid, varying in size from that of a pea to that of a small kidney-bean, the average diameter being one-third of an inch. On dissecting or breaking up a mease it will be seen that the great vesicular portion constitutes the bladder-like caudal extremity of the *cysticercus*, while the head, neck, and body can be drawn out so as to exhibit a vermiform character.

In the article GENERATIONS, ALTERNATION OF, it was stated that the group of phenomena included in that term would be further illustrated in the history of the tapeworm. From what has been already shown it appears that "we have a simple alternation of generation in which the immediate product of the proglottis (or sexually matured zooid individual) is a six-hooked brood; by metamorphosis the latter becomes transformed into the *cysticercus*, having a head with four suckers, and a double crown of hooks; and by gemmation the latter gives rise to a whole colony (strobila) of individuals, the greater part of which are destined to become sexually mature—zooid individuals or proglottides. It will be observed, therefore, that the product of a single ovum is, in the first instance, a single non-sexual embryo; in the second phase, it becomes a non-sexual *cysticercus* (these two phases together constituting the protozooid); in the third change it gives off, by budding, numerous gemmules, most of them destined to be sexually mature individuals (or deuterozooids), in this way resembling their original parents. The relation and nature of these developmental changes may be further simplified by placing the various life phases in a tabulated form as follows:

- | | |
|--|---------------|
| (a.) Egg in all stages. | } Protozooid. |
| (b.) Six-hooked embryo = proscölex. | |
| (c.) Resting larva, or <i>cysticercus (telæ) cellulosæ</i> (scolex). | |
| (d.) Immature tapeworm. | |
| (e.) Strobila, or sexually mature <i>tenia solium</i> . | |
| (f.) Proglottis (cucurbitinus) = free segment = deuterozooid. | |

—Cobbold, *Entozoa*, pp. 221, 222.

How long a tapeworm can naturally exist in an intestinal canal is not known; but there is doubtless a period at which the parasite spontaneously separates from the intes-

tinal mucous membrane of its host—a period probably coinciding with the shedding and non-renewal of the cirlet of hooks. When this separation occurs, the whole length of the worm is expelled, in the same manner as if the parasite had been first killed by the administration of a vermifuge medicine. From this history of the structure and life-history of this organism, which applies with slight difference in minor points to all other tapeworms, we proceed to describe the injurious effects which the worm in its adult and larval stages produces on man, and the precautions which should be taken to prevent its entrance into the system; while the discussion of the means of expelling it when it has once found a lodgment in the intestinal canal, will be postponed to the article on VERMIFUGES.

The common tapeworm may cause disease, and even death, by its aggressions, either in the adult or in the larval stage of its existence. A mature tapeworm in the intestinal canal may give rise to a series of anomalous symptoms, including "vertigo, noises in the ears, impairment of sight, itching of the nose and anus, salivation, dyspepsia and loss of appetite, colic, pains over the epigastrium and in different parts of the abdomen, palpitation, syncope, the sensation of weight in the abdomen, pains and lassitude in the limbs, and emaciation."—Davaine *Traité des Entozoaires*, etc., p. 103. Many cases are on record in which hysterical fits, chorea, epilepsy, convulsions of various kinds, and even mania, have been induced by the irritation excited by this parasite, and have ceased at once on its removal. But distressing as these symptomatic phenomena may be, their injurious effects are trifling as compared with the troubles which follow the deposition and growth of the larval form within the body, especially when the cysticerci find a home in the more important vital organs. There are at least a hundred cases on record in which the cysticercus has caused death by its development within the human brain. In the present state of our knowledge, it is impossible to diagnose these cases; and even if a correct diagnosis were possible, nothing could be done in the way of treatment. Epilepsy, with or without mania or imbecility, is commonly, but not invariably present in these cases. "Cysticerci," says Dr. Cobbold, "may develop themselves in almost any situation in the human body, but they occur most frequently in the subcutaneous areolar, and inter-muscular connective tissues; next, most commonly in the brain and eye, and lastly, in the substance of the heart and other viscera of the trunk."—*Entozoa*, p. 226. The adult form of the worm enters the system as the cysticercus of mealy pork, and to eat raw or underdone mealy pork is an almost certain means of introducing this parasite into the body. It is satisfactory to know that the temperature of boiling water is quite sufficient to destroy the vitality of the measles; and that in ordinary salted pork, and in hams, they are destroyed by the action of the salt in the one case, and of the combined salt and smoke in the other. Sausages, into which it is to be feared mealy pork too often find its way, are rendered safe if they are cooked till no pink, raw-like, fleshy look can be seen in their center. Butchers are especially liable to tapeworm, in consequence of their touching and cutting mealy pork, and then accidentally transferring the cysticercus by the hand, or even by the knife to the mouth, and by indiscriminately using the same knife for various meats, both butchers and cooks may readily disseminate the infection over various articles of food. The larval worm may gain access into the human body by our swallowing the mature eggs of the tapeworm. Those who, as students of this department of natural history, handle fresh tapeworms, are perhaps especially liable to this misfortune; but, says Dr. Cobbold, "our neighbors, who devour choice salads, also run a certain amount of risk, not only as regards this entozoon, but as respects several others. The vegetables may be manured with night-soil containing myriads of tapeworm eggs, or they may be watered with fluid filth into which these eggs have been cast. In such cases, one or more tapeworm ova may be transferred to our digestive organs, unless the vegetables are carefully cleansed before they appear on the table. In the same way, one perceives how fallen fruits, all sorts of edible plants, as well as pond, canal, or even river water, procured from the neighborhood of human habitations, are liable to harbor the embryos capable of gaining an entrance to our bodies. It thus becomes evident also how one individual suffering from tapeworm may infect a whole neighborhood, rendering the swine mealy, these animals in their turn spreading the disease far and wide." Such a person may also prove dangerous—even fatal to his neighbors directly (without the intervention of a pig), by ejecting mature proglottides, from which thousands of eggs may escape, some of which may readily come in contact with human food or drink, make their way into the stomach, and from thence get into the circulation, and finally to the brain, where they cause convulsions and death. The most remarkable case on record of what may be termed a *measly* man, is one described, in 1864, by Delore, in the *Gazette Méd. de Paris*, and quoted by Dr. Cobbold. He died at the age of 77, from pulmonary catarrh, old age, and fractured neck of the thigh-bone; and on examining his body after death, no less than 2,000 cysticerci were found, of which 111 occurred in the nervous centers.

The tapeworm that ranks next in importance to the *tenia solium* is the *tenia mediocanellata*, which was first established as a distinct species by Küchenmeister only a few years ago. It exceeds the *T. solium* both as regards length, breadth, and the thickness of the individual segments; the head is also somewhat larger, abruptly truncated at the crown, destitute of a proboscis and a hook-apparatus—hence this species has been described as the *hookless tapeworm*—but furnished with very large sucking-disks, sur-

rounded by much dark pigment, which gives the head a blackish appearance. The specific name of *mediocanellata* has reference to an interesting and almost specific character in connection with the water-vascular system, into which we have not space to enter. Lencart has proved by experiment that the measles or cysticerci which produced this worm are to be found in the muscles and internal organs of cattle. He administered proglottides of *T. medicanellata* to three calves, a sheep, and a pig. In the two last-named animals they produced no effect, as was shown by their post-mortem examination; while in the calves they produced a kind of leprosy, which has since been characterized as "acute cestoid tuberculosis," and which proved fatal if too large a dose of eggs was administered. On examining one of these animals after its restoration to health—48 days after the eggs were swallowed—he found numerous cysticercus-vesicles, larger and more opalescent than those of the pig, lodged in the muscles; and as the heads of the contained cysticerci exhibited the distinctive peculiarities presented by the head of the adult worm, "we are supplied with the most unequivocal evidence that man becomes infested with this second form of tapeworm by eating imperfectly cooked veal and beef." Hitherto the two above-described species have commonly been included under *T. solium*, from want of due examination, especially of the head. Dr. Cobbold believes that their respective frequency will ultimately be found pretty well on a par, though probably the *T. solium* will maintain a slight ascendancy, in consequence of the relative cheapness of pork. "Admitting occasional exceptions," he observes, "the hooked worm infests the poor, and the hookless worm the rich. This circumstance accords with the fact, that the lower classes subsist chiefly upon pork, while the wealthier prefer mutton, veal, and roast beef."—*Entozoa*, p. 242. It gives rise to the same symptoms as the *T. solium*.

The next five tapeworms infesting man may be passed over without notice, as being of very rare occurrence. *Tenia acanthotriax* is only known from a single case, in which, in the larval stage, it was found in the muscles of a woman. The last species we shall describe, the *T. echinococcus*, is, in its larval condition, probably more fatally injurious to the human race than all the other species of entozoa put together. In its mature (strobila) condition, in which it is found only in the dog and wolf, it seldom exceeds the fourth of an inch in length, and develops only four segments, including that of the head. The final segment, when sexually mature, equals in length the three anterior ones, and contains as many as 5,000 eggs. The proscœlex or embryo forms large proliferous vesicles, in which the scolices or larvæ (known also as acephalocysts, echinocœci, echinococcus heads or vesicles, pillbox hydatids, etc.) are developed by gemination internally. The eggs develop in their interior a six-hooked embryo, and these embryos are introduced into our bodies with food or water into which the eggs have been carried. "With an especial liking for the liver," says Dr. Cobbold, "they bore their way into this organ, or are carried along the circulating current to other organs. In these situations they sooner or later become transformed into simple vesicular, bladder-like bodies, commonly called acephalocysts or hydatids." Instead, however, of displaying the head, neck, and body of a cysticercus, the vesicle retains a globular figure. Its growth is slow, and many months elapse before echinocœci are developed within our bodies, after we have swallowed the proper tapeworm eggs and their contained embryos. There have been great differences of opinion among physiologists as to the mode of development of these echinocœci; but the following is probably the current view: The inner surface of the vesicle presents after a time slight papille or prominences, which, as they enlarge and become oval, are eventually scoleciform, and contain a cavity filled with a limpid fluid. This scolex-like development produces in its interior a brood of scolices or echinococcus heads, or, in other words, becomes gradually transformed into the so-called "brood-capsules" of helminthologists. It is almost impossible to explain the nature of these brood-capsules, with young echinocœci in their interior, without the aid of such diagrams and illustrations as are given by Cobbold in his chapter on *T. echinococcus*. In the fully developed state the echinocœci vary from $\frac{1}{16}$ to $\frac{1}{10}$ of an inch in diameter. The rostellum supports a double curve of hooks, those in the smaller row varying in size from $\frac{1}{100}$ to $\frac{1}{75}$ of an inch, while those of the larger series are from $\frac{1}{30}$ to $\frac{1}{25}$ of an inch. Below the hooks are four suckers, and the general appearance of the body is finely granulated, from its containing calcareous particles. It often happens that the discovery under the microscope of a few of these little hooks at once decides the nature of an otherwise mysterious tumor. Of 373 cases of the parasite occurring in man, collected by Davaine (who devotes more than one-third of his *Traité des Entozoaires* to this subject, 165 affected the liver, 40 the lungs, 30 the kidneys, 20 the brain, and 17 the bones, while the remainder were spread over other parts; and of 136 cases collected by Cobbold, 51 affected the liver. No less than 35 of these 51 cases recovered. "Four of them were complete natural cases; two others being also temporarily cured in the same. All the rest were cured by surgical operations." It is impossible to state with accuracy the degree of prevalence of hydatids in this country, or the extent to which it proves fatal. In Iceland this disease is endemic to such a degree that about one-sixth of the population are affected with it. It produces a long illness, terminating with a painful death, and no means of cure have yet been discovered. Its prevalence in that island may be rationally accounted for. Firstly, every peasant has, on an average, six dogs, all of which are probably infested by the

mature tapeworm; and secondly, there being only six legally authorized medical men, the great majority of the population (over 10,000 persons, scattered over 1500 sq. in.) are in the hands of quacks, whose principal treatment consists in the administration of *fresh dog-excrement!* Our authority for this astounding specimen of homeopathic treatment is Leuckart, whose admirable popular essay, *On the Newest Discoveries regarding Human Intestinal Worms, and their Importance in Relation to Hygiene*, in the *Conversations Jahrbuch* (1863), is deserving of the most careful study. For an excellent abstract of the remarkable series of experiments—extending from 1851 to the present day—by which the relationship between the so-called cystic worms and the cestoid worms was established, we may refer the reader to Aitken's *Science and Practice of Medicine*, vol. i.; while for the subject of tapeworm generally, the highest authorities are the works of Küchenmeister and Siebold, translated by the Sydenham society; Davaine's *Traité des Entozoaires*; Weinland's *Essay on the Tapeworms of Man*; Lueckart's *Das Menschliche Parasiten* (not yet completed); and Cobbold's *Entozoa* (1864), a work equally remarkable for the vast amount of original research which it contains, and for the beauty and correctness of the illustrations.

Tapeworms, although rare among horses and cattle, are common in dogs and sheep, causing irritability of the bowels, and an unthrifty appearance. For dogs no remedy answers as well as powdered area nut, of which 30 grains suffice for a dog weighing about 20 lbs. It is best given after 10 or 12 hours' fasting, in a little soup or milk, and should be followed in a few hours by a dose of castor oil. Neither area nor any of the approved remedies used in men, prove effectual in sheep; and one of the best prescriptions for them consists of 40 drops of oil of turpentine, a dram of powdered green vitriol, and an ounce of common salt, given mixed in a little milk or gruel, or, where their bowels are confined, in linseed oil. A daily allowance of linseed cake and sound dry food should likewise be given with the grass or roots, and pieces of rock-salt left within the animal's reach.

TAPIOCA. See MANIOC and CASSAVA.

TAPIR, *Tapirus*, a genus of *pachydermata*, of the section *ordinaria*; having a bulky form, with moderately long legs; the fore-feet four-toed, the hind-feet three-toed; the skin thick, the hair short; the tail very small; the neck thick; the ears short; the eyes small; the muzzle elongated; the nose prolonged into a short, flexible proboscis, which, however, does not terminate in an organ of touch and prehension, like that of the elephant; 6 incisors, 2 canine teeth, and 14 molars in each jaw, the molars separated from the canine teeth by a wide interval. The best known species is the AMERICAN TAPIR (*T. Americanus*), which is about the size of a small ass, and is common in almost all parts of South America, its range extending as far s. as the strait of Magellan, although it suddenly ceases to be found at the isthmus of Darien. Its color is a uniform deep-brown, but the young are beautifully marked with yellowish fawn-colored stripes and spots. The skin of the neck forms a thick rounded crest on the nape, with a short mane of stiff hair. The tapir inhabits deep recesses of the forest, and delights in plunging and swimming in water. It feeds chiefly on young shoots of trees, fruits, and other vegetable substances, but is ready to swallow almost anything that comes in its way. Pieces of wood, clay, and pebbles are often found in its stomach. It sometimes commits great ravages in cultivated grounds; a large herd of tapirs sallying forth from the forest by night, trampling and devouring all that they find in the fields. The tapir is a very powerful animal, and, protected by its thick hide, forces its way through the forest where almost no other quadruped can. When assailed by the jaguar it seeks to get rid of him by rushing through thick underwood, and if it can reach water is often successful by plunging in and diving. It is inoffensive, never attacking man; but when hard pressed by dogs makes a violent resistance, and inflicts severe bites. It is very easily tamed, and becomes extremely familiar; but its large size makes it a troublesome pet. Its hide is useful, and its flesh is eaten, although rather dry.—The MALAYAN TAPIR (*T. Malayanus* or *Indicus*) is found in Malacca, Sumatra, etc. It is larger than the American tapir, and its proboscis is rather longer in proportion. The neck has no mane. The color is glossy black, except the back, rump, and sides of the belly, which are white. The colors do not pass gradually one into another, but the line of separation is marked, giving the animal a very peculiar appearance. The habits of this species are very similar to those of the American tapir, and it is equally capable of domestication. The young are striped and spotted as in that species.—A third species is found in the mountainous parts of South America.

The remains of tapirs have been found in miocene and subsequent strata. In all about 12 species have been determined. Tapir-like animals are common in eocene beds. Ten species of *palaotherium* (q.v.) have been described. *Lophiodon*, of which 15 species have been observed, differs from *palaotherium* in the structure of the teeth of the lower jaw—and from other peculiarities in the same organs, *coryphodon* (containing three species) has been separated from both genera.

The tapir is a remarkable exception to the generalization deduced from the comparison of the later tertiary mammals with those living in the same districts at the present day, viz., that there is a close correspondence between the fauna of the two periods. The pliocene and post-pliocene bears, hyenas, tigers, elephants, etc., of Europe and Asia

are represented by living species of the same or nearly allied genera. The recent sloths, armadillos, and prehensile-tailed monkeys of South America were preceded by closely related forms in the later tertiary period; as were also the marsupials of Australia. Several species of tapirs have been found in Europe, but they have left no representatives nearer than eastern Asia and South America.

TAPPAN, ARTHUR, 1786-1865; b. Mass.; received a common school education; was clerk in a hardware store in Boston, 1800-7; removed to Montreal, Canada, but after the breaking out of the war (1812) he established himself in New York in the dry-goods importing business in 1814, where he was greatly prospered. He was one of the founders of the American tract society, and gave liberally for its first building; aided in establishing and endowing Lane theological seminary (Presbyterian), Cincinnati; founded a professorship in Auburn seminary; erected Tappan hall, Oberlin; established with his brother Lewis the *Journal of Commerce*, New York, 1838. A vigorous opponent of slavery, he established at his own expense the *Emancipator*, 1833; originated the New York city anti-slavery society; was appointed president of the American anti-slavery society formed in Philadelphia, contributing to it for some time \$1,000 per month; failed in 1842 and went into bankruptcy, giving up all his personal property. He was afterward connected with the "mercantile agency" established by his brother. He left a high reputation for integrity, earnestness, and benevolence.

TAPPAN, BENJAMIN, 1773-1857, b. Mass.; brother of Arthur and Lewis; at first a copper-plate engraver and printer. After giving considerable attention to portrait-painting he studied law, and was admitted to the bar. In 1803 he was a member of the legislature of Ohio, whither he had removed in 1799. He served in the war of 1812 as an aid-de-camp to gen. Wadsworth. He was afterward for several years presiding judge of the 5th Ohio circuit. In 1833 he became U. S. district judge for Ohio. He was U. S. senator, 1839-45. He was connected with the democratic party till 1818, when he became a free-soiler. He published in 1831 a volume of *Reports* of cases in the court of common pleas.

TAPPAN, DAVID, D.D., 1752-1803; b. Mass.; graduated at Harvard college, 1771; studied theology two years; became pastor of the third church (Congregational), Newbury, Mass.; Hollis professor of divinity in Harvard college, 1792, in which position he remained till his death. He published about 30 sermons and addresses, and after his death appeared *Sermons on Important Subjects*; *Lectures on Jewish Antiquities*.

TAPPAN, HENRY PHILIP, D.D., b. N. Y., 1806; graduated at Union college, 1825; studied theology two years at Auburn seminary; assistant pastor of the Reformed church, Schenectady, N. Y.; pastor of a Congregational church, Pittsfield, Mass., 1833-31; professor of mental and moral philosophy in the university of New York, 1832-38; taught a private school for several years in New York; chancellor of the Michigan university, 1852-63; elected corresponding member of the French imperial institution, and president of the American association for the advancement of education. He published *A step from the New World to the Old*, the results of his inquiry into the working of university education in England and Prussia; *Review of Edward's Inquiry into the Freedom of the Will*; *The Doctrine of Will Determined by an appeal to Consciousness*; *The Doctrine of the Will Applied to Moral Agency and Responsibility*; *Elements of Logic*; *Illustrations of Personages of the Nineteenth Century*; *Treatise on University Education*. His three works on the will were republished in Glasgow.

TAPPAN, LEWIS, 1788-1873; brother of Arthur and Benjamin; b. Mass.; was a merchant and cotton manufacturer in Boston; removed to New York in 1827; joined his brother Arthur in establishing the *Journal of Commerce*, of which he was sole proprietor, 1828-31. He took a decided stand against slavery, and for his abolition sentiments and efforts his house was sacked by a mob in 1834; failed in the financial disaster of 1837; established a "mercantile agency." He was active in anti-slavery and benevolent associations; was treasurer and president of the American missionary association, founded mainly through his efforts, and one of the early members of Plymouth church, Brooklyn. He published a *Life of Arthur Tappan*.

TAPPAN BAY, or TAPPAN SEA, reaches from a point about 24 m. n. of New York for a distance of 12 m., being an enlargement of the Hudson river. Its greatest width is 4 m., and it lies between Rockland and Westchester counties, N. Y.

TAPPING is an operation which is most commonly performed on the abdomen, but occasionally on the chest and head. Tapping of the abdomen gives great relief when the abdomen becomes inconveniently distended with fluid contained in the peritoneal sac, or, in the case of the female, in an ovarian cyst. A small incision is then made about 2 in. below the navel, through which the cutting surfaces of the trochar—the instrument used in this operation—are passed. By arrangements, into which we need not enter, the fluid escapes through this instrument. The wound made by the trochar in the abdomen will, in ordinary cases, heal in a few days.

Tapping of the chest is an operation which is occasionally required for the relief of empyema and other effusions in the cavity of the pleura. Tapping of the head has been occasionally found successful in hydrocephalus. Tapping of the pericardium has been

practiced in cases of pericardial dropsy, but it is an operation not to be recommended under any circumstances.

TAPTĪ, a river of the British presidency of Bombay, India, rises in the Saugur and Nerbuddah territories, in lat. about $21^{\circ} 46'$ n., flows w. through Scindhia's dominions and the districts of Candesh and Surat to its mouth in the gulf of Cambay, 17 m. below the town of Surat. It is 441 m. in length; but can hardly be said to be navigable, for even small vessels of from 40 to 50 tons burden cannot ascend higher than Surat.

TAR is a well-known substance, for which it is difficult to frame a definition, since it varies in composition, color, and consistence, and is derived from all three kingdoms of nature. In various parts of the world it occurs as a natural mineral product, and is known under the various names of bitumen, asphalt, petroleum, natural tar. See NAPHTHA. As an animal product, a species of tar is obtained from the destructive distillation of bones employed in preparing bone-black. The distillate, which possesses a most offensive odor, separates into a heavier layer of black animal tar—commonly known as *bone-oil*, or *Dippel's animal oil*—and a lighter layer of watery solution of sesquicarbonate of ammonia, commonly known as *bone-liquor*, and much employed in the preparation of various salts of ammonia. This animal tar is chiefly used for the lubrication of machinery. The vegetable kingdom is, however, the most important source of tar. On submitting wood to destructive distillation in closed vessels, we obtain a large number of products, which are described in the article WOOD, DISTILLATION OF; some are gaseous and some liquid, and of the latter one portion is soluble and the other insoluble in water. This insoluble portion constitutes wood-tar, and is composed of a mixture of various liquids holding solid matters in solution or in suspension. Among its most important constituents, professor Miller mentions several forms of hydrocarbon, such as toluol, C_7H_8 ; xylool, $C_{10}H_{10}$; cymol, $C_{10}H_{14}$; and eupion, besides a number of oxidized compounds, including cresote, $C_{10}H_{16}O_4$, picamar, and kapnomar, $C_{20}H_{11}O_2$; while among the solid portions are resinous matters resembling colophony, and a waxy substance named paraffin, and many other substances, such as naphthalin, cedriect, pittacal, pyrene, $C_{20}H_{12}$; chrysene, $C_{18}H_{14}$; and pyroxanthin. (When the formula is not given, the exact composition of the substance is not determined with certainty.) The *Stockholm tar*, which is so widely used in ship-building, and the *American tar*, which is almost equally celebrated, are chiefly prepared from the resinous wood of the pine, and especially of the root of the tree. The specific gravity of ordinary tar is about 1.040. Peat yields a tar very similar to wood-tar. Coal yields, on distillation in closed vessels, even a larger number of products of distillation than are yielded by wood. In addition to numerous gaseous products, the liquid portions contain water and various forms of hydrocarbon, which collectively form the liquid known as *coal-naphtha*; besides which there is a large quantity of a dark viscous matter known as *coal-tar*. The mixture of naphtha and tar is described in this work under the title of GAS-TAR. For an account of the beautiful *coal-tar colors* or aniline dyes, see the articles DYE-STUFFS and PHENYL. The distillation of coal-tar is conducted on an extensive scale as a separate branch of trade. From Miller's *Organic Chemistry* we extract the following remarks on the compounds present in this substance: "Of the substances contained in coal-tar, some are basic, and some acid, but the principal portion consists of neutral or indifferent bodies. The bases include ammonia, aniline, picoline, quinoline, and pyridine. Among the acids, the acetic is present in small amount; but the most important is phenic acid, the carbonic acid of Runge. This chemist also mentions two other acids named *rosolic* and *brunolic* acids. The neutral substances contain several hydrocarbons, including benzol, toluol, cumol, and cymol, which are among the liquid constituents; while naphthalin, anthracene, chrysene, and pyrene are among those which are solid at ordinary temperatures." When either wood-tar or coal-tar is submitted to distillation, the solid brown or black residue left in the retort constitutes *pitch*.

Wood-tar, under the title of *Pice liquida*, is included in the pharmacopœia, in which its character is given as follows: "Thick, viscid, brownish-black, of a well-known peculiar aromatic odor. Water agitated with it acquires a pale-brown color, sharp, empyreumatic taste, and acid reaction." Tar was more used in medicine in former times than at present. Bishop Berkeley's commendatory essay on the use of tar-water in diseases of the chest and kidneys, is well known to all literary students. (See Chambers' *Book of Days*, vol. i. p. 108.) Since his time the inhalation of tar-vapor has been highly recommended in cases of phthisis; and tar capsules are still occasionally prescribed in cases of relaxed mucous membrane. In the present day, tar is, however, seldom used except as a local stimulant in chronic cutaneous diseases.

In modern commerce there are two kinds of wood-tar known—that made in the north of Europe from the wood of *Pinus sylvestris*, and the North American, which is made from *Pinus rigida*, *P. taeda*, *P. Australis*, &c. The distillation is usually performed in a very rude manner: a funnel-shaped hole is dug in a bank, about 6 or 8 ft. in diameter at the upper part, and not more than 18 in. at the lower. At the bottom of the hole is placed an iron pan, having a long spout or pipe, which is made to pass through the bank; the hole is then filled up with billets cut from the roots and branches of the pine trees, which, after being kindled at the top, are covered over completely with turf. The wood is thus charred from above downward; and the tar, mixed with various other pro-

ducts, flows off at the bottom through the spout into a receiver. A somewhat similar product is obtained in the distillation of coal for gas, and in the distillation of bones in forming animal charcoal. Formerly, the chief value of these materials was as a preservative coating for exposed wood-work, ships' sails, ropes, &c., in consequence of their very highly antiseptic properties. A better knowledge of their chemical history has, however, much increased their value. The imports of wood-tar into Great Britain exceed five millions of gallons annually; while the supply of coal-tar produced in the gas-works, charcoal-works, and bone-works of the United Kingdom cannot be estimated at much under that quantity.

TARA, or **TARO**, *Colocasia macrorrhiza*, a plant of the natural order *araceæ*, of the same genus with the cocco (q. v.), or eddoes, and cultivated for its roots, which are a principal article of food in the South Sea islands. The roots are 12 to 16 in. long, and as much in girth. They are washed to take away their acidity, which is such as to cause excoriation of the mouth and palate. They are cooked in the same way as bread-fruit, the rind being first scraped off. A pleasant flour is made of tara. Many varieties are cultivated. The plant has no stalk; broad, heart-shaped leaves spring from the root; and the flower is produced in a spathe. The leaves are used as spinach.

TARA FERN, *Pteris esculenta*, a species of brake (q. v.), the root (rhizome) of which was one of the principal articles of food of the New Zealanders, before the settlement of New Zealand by British colonists. This fern comes to perfection only in good soils, and there the plant is ten ft. high. Plants three years old furnish the best roots, which are about an inch in circumference. The root, being dug up, is cut in pieces about 9 in. long, and placed in stacks, carefully protected from rain, but through which a current of air blows. Fresh fern-root is not good; it is the better for being a year above ground. Before being cooked, it is steeped in water, and dried in the sun. It is then roasted. A large quantity of a very pleasant flour is obtained from it by beating on a stone, the fiber alone being thus left.

TARANNON SHALE, the upper member of the Llandovery formation of the Silurian rocks (q. v.). It consists of shales, or pale, sometimes purple, slates with very few fossils.

TARANTISM may be defined a leaping or dancing mania, originating in, or supposed to originate in, an animal poison. The name is supposed to be derived from the ground-spider, *tarantula* (q. v.), which conveyed the poison into the human body by its bite. The gesticulations, contortions, and cries somewhat resemble those observed in St. Vitus's dance, and other epidemic nervous diseases of the middle ages, with which tarantism was contemporaneous; but the affection differed from these in its origin, in the cachexia present, in the elegance of the movements of the victims, in their partiality for red colors, bright and luminous surfaces, their passion for music, and in their restoration depending upon the use of instrumental or vocal music as a remedy. Although the sufferers were subjected to extraordinary treatment, such as being buried up to the neck in earth, the success of music was so universal and invariable, that a class of tunes and songs was composed, called *tarantella*, to be employed in the cure of the tarantati. These have lingered long after the extinction of the malady, and may still be heard in the wilder districts of Italy. While it is highly probable that the physical symptoms were due to the bite of spiders, the mental disturbances and muscular *agitation* should be traced to the secondary effects of these upon the nervous system and imagination. It appeared in various parts of Italy, but was most prevalent in Apulia, where the insects abound. No age or class appears to have been exempt, for we read of a philosophic bishop who allowed himself to be bitten by a tarantula, dancing, etc., as fast and furiously as the peasantry.—Hecker, *Epidemics of Middle Ages*, p. 110; Madden, *Phantasms, or Illusions and Fanaticisms*, vol. i. p. 415; Milligen, *Curiosities of Medical Experience*, p. 88.

TARANTO (anc. *Tarentum*), a town of s. Italy, in the province of Lecce, is situated on a rocky islet, formerly an isthmus, between the Mare Piccolo (Little Sea), an extensive harbor on the e. or landward side of the town, and the Mare Grande (Great Sea), or gulf of Taranto, on the west. The natural channel between the two "seas" has been spanned by a long bridge of seven arches, rendering the Mare Piccolo quite useless as a harbor, and forcing ships to anchor in the outer roads, which are much exposed to s. and s.w. winds. The principal buildings are a cathedral dedicated to St. Cataldo, a native of Raphoe in Ireland, who was first bishop of Taranto; a fine episcopal palace; a castle and fortifications, erected by Charles V., and commanding both seas; and two hospitals. The streets are as narrow and dark as those of an oriental city. Taranto has manufactures of velvets, linens, and cottons, but little commerce. The Mare Piccolo, however, is still famous (as of yore) for its immense abundance of shell-fish, and a considerable portion of the population (which in 1872 amounted to 27,546) derives its subsistence from the oyster and mussel fisheries.

Ancient Tarentum, however, was a far more famous and splendid city than its modern representative. Founded by a body of Spartan emigrants about 708 B.C., it grew and prospered for centuries in happy obscurity. Its territory was not perhaps very fertile, but its pasturage was of the finest, and its olive groves were unsurpassed. Yet it

was not these things that ultimately made it the sovereign city of Magna Græcia; this rank it attained through the supreme excellence of its harbor (the Mare Piccolo), ample and secure beyond all the other harbors of lower Italy. Gradually it became the chief emporium of the Græco-Italian trade, and long after all the rest of the colonial cities in Magna Græcia had fallen into decay, Tarentum was "blooming alone" in undiminished prosperity. We may pass over its earlier history, noticing only the fact, that in the 4th c. b.c., it had for its *stratigos*, or general (seven times), the philosopher and geometer Archytas, under whom it became the headquarters of the Pythagorean sect, and was honored with a visit from Plato, who was the guest of Archytas during his residence there. But while in the very acmé of its greatness, it provoked a quarrel with Rome (q.v.), 281 b.c., in which, though aided by the gallantry of Pyrrhus (q.v.), king of Epirus, it was utterly crushed, after a struggle of less than ten years; and though its natural advantages hindered it from sinking into such absolute insignificance as other cities of Magna Græcia, it was never after a place of great importance. Under the empire it was quite overshadowed by Brundisium on the Adriatic, but rose again during the Gothic wars, and passed into the hands of the Saracens and Greeks, from the latter of whom it was wrested by Robert Guiscard, the Norman, in 1063. Since then, it has shared the fortunes of the kingdom of Naples. Few relics of the classic Tarentum are extant, the chief being bits of an amphitheater, a circus, and traces of some of the temples.

TARANTULA, *Lycosa tarantula*, a species of spider, of a genus to which the name wolf-spider is often given, a native of the s. of Europe. It derives its name from the city of Taranto, in Italy, where it is very plentiful. It is one of the largest of European spiders, of a somewhat elongated shape, with rather long legs. It is one of those spiders which seek their prey by hunting. Its bite is much dreaded, and has been supposed to cause the disease called *tarantism* (q.v.).—Several species of spider nearly allied to the tarantula are found in different parts of the s. of Europe. One of them (*lycosa narbonensis*) frequents dry uncultivated grounds in the s. of France, and makes a little pit in the ground, near the entrance of which it sits watching for prey. The prey is carried into the pit to be devoured. The female shows great affection for her young.

TARARE, a thriving and important manufacturing t. of France, in the dep. of Rhone, stands at the foot of mount Tarare, one of the highest summits of the Beaujolais range, 21 m. n.w. of Lyons. Formerly unimportant, it is now a rich and flourishing town, the inhabitants of which are engaged in the manufacture of muslins, cloth, silk, and merino fabrics, and in embroidering and bleaching. The muslins of Tarare are famous for their fineness. See TARLATAN. Pop. '76, 13,563.

TARASCON, a t. of France, in the dep. of Bouches-du-Rhone, 13 m. s.w. of Avignon by railway. The church of St. Martha dates from the year 1187, and is so called after Martha, the sister of Lazarus, and the patron saint of the town. Woolen and silk fabrics, and brandy and vinegar, are manufactured. Pop. '76, 7,777.

TARAXACUM, or dandelion (q.v.) root, is employed to a considerable extent in medicine. The roots should be gathered in August and September, when the juice is most abundant. There is no very satisfactory analysis of this juice, but it is said to contain mannite, resin, sugar, gum, caoutchouc, and a crystallizable matter termed *taraxicine*, on which its active properties probably depend. This medicine may be prescribed with advantage in the form of extract, decoction, or juice in chronic diseases of the liver, and in certain forms of dyspepsia and skin-disease which are accompanied by derangement of the biliary organs. In very large doses, it has a diuretic and slightly aperient action.

TARAZONA, a t. of Spain, in the province of Saragossa, 52 m. w.n.w. of the city of that name, on the Queyles, a tributary of the Ebro. It stands on a wind-blown plain, exposed to bleak winds from the Sierra de Moncayo on the s., and from the Pyrenees on the north. It is the see of a bishop; and contains a cathedral with a slender brick spire and rich interior, a bishop's palace, and a Moorish *Alcazar*. Pop. upward of 6,000, mainly engaged in agriculture.

Tarazona is the ancient *Tarúso*; and here a few Roman troops routed a Celtiberian army. It became a municipium under the Romans; and under the Goths, by whom it was fostered, it became famous for its steel.

TARBAGATAI, a frontier t. of Chinese Turkestan, 170 m. e. of the eastern extremity of lake Balkash, in lat. 46° 44' n., long. 82° 28' east. It stands at the foot of the mountains of the same name, in a plain watered by the Imil, and with extensive meadows and pasture-grounds in the vicinity. The inhabitants consist of 3,000 exiled Chinese, 1000 of a Chinese garrison, and a number of Mongolian merchants. The trade with Russia is important.

TARBES, a t. in the s. of France, capital of the dep. of Hautes-Pyrénées, stands on the left bank of the Adour, 23 m. e.s.e. of Pau. It is a station on the *Chemin de fer du Midi*, and the center of communication with all parts of the Pyrenees, the lofty line of which bounds the prospect on the south. The modern cathedral is the principal and indeed the only notable building. There is here a *haras*, or government stud, for the improvement of the breed of horses. Tarbes is the seat of an active general trade. Pop. '76, 11,080

Tarbes dates from the time of the Romans, and its bishopric was founded in the year 420.

TARDIGRADA. See **SLOTH**.

TARE, *Ereum*, a genus of plants of the natural order *leguminosæ*, sub-order *papilionaceæ*, distinguished from *vicia* (see **VETCH**), to which it is nearly allied, by a capitate stigma, downy all over. It contains only a few species of weak climbing plants, natives of the temperate parts of the Eastern Hemisphere. One of these is the **LENTIL** (q.v.).—Two (*E. hirsutum* and *E. tetraspermum*), generally known by the name of **TARE**, are common in cornfields and hedges in Britain. They have very small flowers and pods; the leaves are pinnate, and the leaflets small. They afford nourishing food for cattle, but the quantity is so small that they are not worthy of cultivation, and are chiefly known as a nuisance in cornfields. A species of tare (*E. sativum*), with an upright branching habit, is cultivated in some parts of Europe for its herbage, which is used for feeding cattle. The bulk of herbage is small, but its nutritious character is thought to compensate for this. The leaves have from 8 to 14 pair of leaflets. The plant thrives well in poor sandy soils.—It is not supposed that the *tare* of the New Testament has any affinity to these plants: it is doubtful what it is, but it appears not improbable that it is the **DARNEL** (q.v.).

TARE AND TRET, certain deductions usually made from the gross weight of goods. *Tare* is the weight of the box, cask, bag, or wrapping in which the goods are contained; and the amount is obtained either by weighing the empty package its lf, by taking an average of a few similar packages of equal size, or by mutually agreeing upon a certain proportion of the gross weight. The remainder, after deducting the tare, is the *net weight*. Another deduction, at the rate of 4 lbs. for every 104 lbs., or $\frac{1}{26}$ of the *ret* weight, is then made, as an allowance for waste through dust, etc., and is called *tret*. Some other allowances of minute magnitude as draft, cloff, etc., are occasionally made after tret, but they are falling into disuse.

TARGET (root uncertain, but the word, in some form, found in all European languages), in its modern sense, is the mark for aiming at in practicing with the cannon, rifle, or bow and arrow. In its more ancient meaning, a target or targe was a shield, circular in form, cut out of ox-hide, mounted on light but strong wood, and strengthened by bosses, spikes, etc. Of modern targets, the simplest is that used for archery (q.v.). With regard to rifle targets, the spread of the volunteer movement and the numerous rifle-matches have caused ranges to be constructed over the whole country. The necessities are: a butt, artificially constructed or cut in the face of a hill, to prevent wide balls from scattering—a marker's shot-proof cell, near the targets—and a range of such length as can be procured. The sizes of targets used by the British army are as follows: for firing up to 300 yards, the target is 6 ft. high by 4 ft. broad, with a circular bull's-eye 1 foot in diameter, and a center of 3 feet. Up to 600 yards, the target is 6 ft. square; bull's-eye, 2 ft. diameter; center, 4 feet. Up to 800 yards, the target is 6 ft. by 8; bull's-eye, 3 ft. in diameter; and center, 5 feet. The marker signals the "hits" from his box, denoting a bull's-eye by a red-and-white flag, a center by a blue flag, and an outer by a white flag. If he show a red flag, it is to cease firing while he inspects the target. In scoring, the outer counts 2; center, 3; and bull's-eye, 4. A red flag should fly on the butt during the whole time of practice, to warn passers-by to keep off the range. The targets used by the National rifle association at Wimbledon are not the same as those used by the army. According to the Wimbledon regulations of 1876, the target for the distance of 200 yards had a circle of 40 in. diameter, divided into the circular bull's-eye 8 in. in diameter, a center of 16 in. diameter, an "inner" of 28 in., the rest of the 40 in. being accounted "outer." On the target for 500 and 600 yards, the circle of 70 in. falls into a bull's-eye of 22 in. diameter, center 38 in., inner 54 in., and the rest outer. The rectangular frame for 800, 900, and 1000 yards distance had a circular bull's-eye of 3 ft. in diameter, a center 4 ft. 6 in., a square inner of 6 ft., the remainder of the target counting as outer. Of the ordinary Wimbledon targets for 1879 (as in 1878), that for 200 yards distance is divided into a bull's-eye 8 in. in diameter; "inner," 1 foot; "magpie," 2 ft.; and outer, the remainder of the target 4 ft. square. At 500 and 600 yards, the bull's-eye is 2 ft. in diameter; the inner, 3 ft.; the magpie, 4 ft.; and outer, the rest of the target of 6 ft. square. At 800, 900, and 1000 yards, the bull's-eye is 3 ft. diameter; inner, 4½ ft.; magpie, 6 ft. square; and outer, the rest of the target of 12 ft. by 6 feet.

Previous to the inaugurating of the Wimbledon meeting in 1860, all targets were circular, and made of iron. From that year till 1873 inclusive, they were square iron plates; but in 1874 targets of canvas stretched on an iron frame were introduced.

TARGOWITZ, or **TARGOWICZA**, in Russia, a small t. in the government of Kiev (q.v.), on the borders of Kherson, was the scene (May, 1792) of a confederation ("plot") as the patriots had it) of the five Polish nobles (Potocki, Branecki, Bzurański, and two others of little note) who were adverse to the constitution of May 3, 1791. They were incited to this traitorous conduct toward their country by Catherine II., and after their conduct had been fully unveiled, they were declared traitors to their country, and only escaped death by precipitate flight to Russia, where they were munificently rewarded for

the treason which had given the czarina a pretext for executing the second partition of Poland (q.v.).

TARGUM (Chaldee, from *tirgem*, a word of uncertain origin, designating to translate, explain), the general term for the Aramaic versions of the Old Testament, which became necessary when, after and perhaps during the Babylonian exile, Hebrew began to die out as the popular language, and was supplanted by "Chaldee," an idiom, or rather a family of idioms, on which we have spoken under **SUEMITIC LANGUAGES**.

The origin of the Targum itself is shrouded in mystery. The first signs of it—as an already fixed institution—have been found by some in the book of Nehemiah, and according to tradition, Ezra and his coadjutors were its original founders. However this be, there can be no doubt that its beginnings belong to a comparatively early period. The Mishna (q.v.) contains a number of strict injunctions respecting it, and also respecting a certain guild of *meturgemans* (whence *dragoman*) or interpreters, who had sprung up as professional followers of those learned men who, at a previous period, had volunteered their services in the translation and paraphrastic interpretation, both activities, as we said, implied by the term. At first, and indeed for many centuries, the Targum was not committed to writing, for the same reason that the "oral law" itself was not at first intended ever to become fixed as a code for all times. In the course of time, however, both had to yield to circumstances, and their being written down was considered preferable to their being utterly forgotten, of which there was no small danger. Yet a small portion only of the immense mass of oral targums that must have been produced, has survived. All that is now extant are three distinct targums on the Pentateuch, a targum on the prophets, targums on the Hagiographa, viz., on Psalms, Job, Proverbs, the five "Megilloth" (Song of Songs, Ruth, Lamentations, Esther, Ecclesiastes), two targums on Esther, one on Chronicles, one on Daniel, and one on the apocryphal pieces of Esther. The most important of the three Pentateuch targums is the one named after Onkelos (q.v.), probably a corruption of Akylas, whose Greek version had become so popular that this Chaldee version was honored with being called after it. In its present shape, this translation dates probably from the end of the 3d or beginning of the 4th c. A.D., although snatches of it were collected and written down more than a hundred years earlier. We have spoken of its language and its general character already under **ONKELOS**, and may here briefly state that it is composed in an Aramaic closely resembling that of Daniel, and that it is as excellent a translation "for the people," which it meant to be, as can well be conceived. Occasionally, when the subject imperatively demands it, it introduces some paraphrastic by-work, and it only deviates from the text where the divine dignity would have appeared to suffer in the eyes of the multitude by a literal interpretation. Its value for exegetical purposes is no less great than it would be for linguistic and antiquarian purposes, were it more explored with that view than has been the case as yet.

The two other Targums on the Pentateuch, hitherto known as Targum Jonathan ben Uzziel, and Targum Jerushalmi, are merely recensions of one and the same version—the name of the first recension being merely a perpetuated error of a single scribe—which owes its origin to Palestine or Syria (Onkelos being of Babylonian origin), and cannot well have been redacted before the 7th c. A.D. There is no doubt that originally this "Jerusalem Targum" embraced the whole of the Old Testament, as did the Babylonian; but nothing has survived beyond these two recensions of the Pentateuch, the first complete, the second in a fragmentary condition: the former probably intended as an emendation of Onkelos, chiefly in the direction of homiletic paraphrase and legendary lore, and the latter as a further emended emendation of single portions. As a version, this Targum is of small importance; but it is invaluable as a storehouse of allegories, parables, sagas, and the like popular poetry of its time. Its language and grammar are exceedingly corrupt; it abounds, moreover, with foreign—Greek, Latin, Persian, and Arabic—terms; and its general use lies more in the direction of Jewish literature itself, as well as of archaeology and antiquities of the early Christian centuries, than in that of a direct interpretation of the Bible text itself. The Targum on the prophets is generally an erroneously ascribed to Jonathan ben Uzziel, an eminent master of the law at the time of Hillel the elder; the fact being that, except one spurious Talmudical passage, in which mention is made of his having translated the Prophets, this Targum is everywhere else, from the Talmud down to the authorities of the 10th c. A.D., ascribed to one R. Joseph, president of a Babylonian academy in the 4th century. And it would indeed seem as if this statement was completely in accordance with the real facts—if not the writing, but the collection and final redaction of this Targum is ascribed to him. Respecting the nature of this version, it may be said that, while being tolerably literal in the first—historical—books, it gradually becomes a mere frame-work of Midrash (q.v.) or Haggada, which it introduces at every turn and at great lengths. It further contains historical bits, disguised, or rather typified, and some lyrical pieces of rare poetical value. In language and general manner, it resembles Onkelos, with which it is of one growth, place, and date, and of which it forms only a kind of continuation.

To the same Joseph "the blind" to whom the redaction of the foregoing Targum is probably due, is further ascribed a Targum on the Hagiographa. But between him

and the Hagiographical Targums lie, at the least, 600 years; their date being approximately given as about 1000 A.D. Certain distinctions between the different books must further be made. The Targums on Psalms, Job, and Proverbs were probably contemporaneous compositions due to Syria. The two former are more mere paraphrastic than the last, which resembles closely the Syriac version. The paraphrase on the five "Megilloth"—a very late production indeed—is principally a collection of more or less poetical fancies, traditions, and legends, to which the single verse in hand merely seems to furnish the key-note. There is, we need not add, but very little to be found in them of what originally must have formed the Targum on these books; nor is there the slightest hint to be found as to who was the real author or editor of their present form. That it was one man's work, is probable enough, from a certain unity of design and style noticeable in all of them. Their dialect lies somewhat between the e. and w. Aramaic. The Targum on the book of Chronicles—almost unknown until the 17th c.—also belongs to a late period, and was probably composed in Palestine. There are some useful philological, historical, and chiefly geographical hints to be gleaned from it, but nothing more; least of all can it be used exegetically. A Persian version of a Targum on Daniel (unedited) is all that has been discovered on that book as yet. It was probably composed in the 12th c., the influence of the early Crusades being plainly visible in it. On the paraphrase of the apocryphal pieces of Esther, we shall not dwell here, any more than on the scanty fragments of a "Palestinian Targum" that are found either interspersed in the general (Babylonian) Targum, or as independent pieces. It seems probable that more of this Palestinian version will come to light some day, as authorities of a few centuries back still quote from it rather largely. At present, however, their quotations are nearly all that remains.

Very little—we might say, next to nothing—has been done as yet to utilize this most important branch of Aramaic literature; in fact, not even an attempt at anything like a critical edition has been made, although it would be difficult to find a more corrupt text than that offered by the MSS. and single printed portions. Some parts have been done into Latin, English, German, etc. The ed. pr. of Onkelos is dated Bologna, 1482; that of the Targum on the Prophets, Leiria, 1494.

TARIFA, a sea port t. of Spain, 20 m. s.w. of Gibraltar. It is the most southern town of Europe, is surrounded by tower-embattled walls, and communicates by a causeway with a small island, on which stand a fortress and light-house. The town is the most thoroughly Moorish in Andalusia; it is quadrangular in shape, and its streets are narrow and dark. Tunny and anchovy fisheries are actively carried on. Pop. 8,300.

Tarifa, the Carthaginian *Josa*, and the Roman *Julia Traducta*, received its present name from the Moors, who are said to have called it after Tarif (= Tarik?) Ibn Malik, who landed there to reconnoiter previous to the conquest of the country. See MUZA; RODERIC. It was successfully defended in 1811 by 2,500 troops (mostly British) against a French force of 10,000 men, under Victor and Laval.

TARIFF (from *Tarifa* (q.v.), where, during the rule of the Moors in Spain, duties were collected), a table or catalogue, generally drawn up in alphabetical order, of the duties, drawbacks, bounties, etc., charged or allowed on different kinds of merchandise, as settled by authority, or agreed to between different states. The principles of the tariffs of different countries depend on their respective commercial policy, and on the fluctuating interests and wants of the community. According to the presently existing British tariff, only about 20 kinds of merchandise are subject to an import duty, and none to an export duty.

TARIFF (*ante*). In the United States the term tariff is used to designate the schedule of duties fixed by congress on imported goods. Considerations of the subject of revenue necessarily entered into the question of the formation of the government of the United States. The period of the adoption of the constitution found the country in the possession of a rich and widely extended territory, but having a sparse population, and an empty treasury. Accordingly congress entertained this subject almost at its first session; since the first meeting having taken place April 6, 1789, on the 8th Mr. Madison, in committee of the whole, introduced the matter of duties on imports; proposing that specific duties should be levied on spirituous liquors, wines, molasses, teas, sugars, pepper, cocoa, and spices; and an *ad valorem* duty on all other articles; also a tonnage duty on American vessels in which merchandise was imported, and a higher rate on foreign vessels. The subject was debated at length; and even at this early period, petitions of manufacturers and others were sent in making recommendations and asking encouragement. The first tariff act became a law under the approval of the president, July 4, 1789. It was comparatively simple, placing specific duty on some forty articles and *ad valorem* duties on all others. On Aug. 10, 1790, a second tariff act was passed, recommended by Alexander Hamilton, secretary of the treasury, which increased the duties by an average of about 2½ per cent. On Mar. 3, 1791, another act was passed, increasing the duties on distilled spirits; and in 1792 a further increase was made by the act of May 2, "for the protection of the frontiers and other purposes." Additional acts passed in 1794 and 1797 were still in the direction of increased duties, and of the application of customs duties to an extended list of articles. Such was also the case with the acts of May 13, 1800, and Mar. 26, 1804; while the acts of Mar. 3, 1807, and Mar. 4, 1808,

repealed the duties on certain articles, notably salt, and evinced a disposition toward greater freedom of trade. The war of 1812, with Great Britain, brought about the passage of the act of July 1, 1812, which imposed an addition of 100 per cent to existing duties; and a further addition of 10 per cent upon goods imported in foreign vessels. The acts of 1813 and 1815 imposed a duty on foreign salt, but repealed the discriminating duties as regarded goods imported in foreign vessels, leaving it to the discretion of the president when to apply such repeal. The tariff act of 1816 brought Henry Clay forward as an advocate of "a thorough and decided protection to home manufactures by ample duties." In the discussions on this bill the theory that protection and not revenue was the prominent object of tariff legislation, was first emphatically advanced. This act, which was essentially protective, became a law on April 27, 1816. In 1824, the principle of "favored nations" first entered into legislation on this question, certain discriminating duties being by law suspended in the case of the Netherlands and Prussia, and the Hanseatic cities of Hamburg, Lubeck, and Bremen. In the same year a new bill was framed and offered, and in the discussion which followed James Buchanan was prominent on the side of protection, and Daniel Webster on that of freer trade, the latter saying that with him "it was a fundamental axiom that the great interests of the country were united and inseparable; that agriculture, commerce, and manufactures must flourish together, or languish together, and that all legislation was dangerous which proposed to benefit one of them, without looking to the consequences that might fall upon the others." This bill, which was less pronounced in the interest of protection than others which had preceded it, passed the house on April 16, 1824, by a vote of 107 yeas to 102 nays. It was materially modified in the senate in favor of greater liberality, and, thus amended, became a law on May 22. The general tendency of tariff legislation continued in the direction of a reduction of duties, as was shown by the acts of 1828, 1830, and 1832; and in 1833, Mr. Clay found it necessary to bring forward his "compromise bill," which was designed to reconcile the opposing factions, and which was passed. By this time the tariff question had become a political one, and whigs and democrats were arrayed on the respective sides of protection, and a tariff for revenue only; to be followed after 1850 by the republicans and democrats, differing after the same fashion. The general tendency has been in favor of the extreme limits of protection; as the United States has grown to become more and more a manufacturing country; and has constantly entered into fresh competition with other manufacturing countries. Under this system have been built up the iron, silk, and other great industries. Meanwhile, it has been urged by free-traders that the conduct of tariff legislation under this system has served to sustain prices at a burdensome figure, and that while large manufacturing industries have been fostered and have prospered, this has been at the expense of the consumer, and to the general injury of the masses of the population. Other objections to a high protective tariff have been that it encourages smuggling and adulteration, opens a way for corruption in legislation and collection of customs; and has organized a vast body of office-holders. Efforts have been made during recent sessions of congress to modify the tariff in the direction of free trade, but have proved fruitless of important results, and unpopular with the majority of the people.

TARIM RIVER. See **TURKISTAN, EASTERN.**

TARLATAN, a thin gauze-like fabric of cotton, used for ladies' ball-dresses, etc. It is usually dyed or printed in colors. Tarare, in France, is the chief center of this manufacture, whence it is largely exported. Switzerland alone competes with France in the production of tarlatan, but those of the latter country far surpass the former in fineness.

TARLETON, Sir **BANNASTRE**, 1754-1833; b. England; a lieutenant-col. in the army of Cornwallis during the revolutionary war. At the head of a loyalist force known as "the British legion," he inflicted considerable damage upon the Americans in the south. He massacred col. Buford's regiment at Waxhaw creek, 1780, but was defeated the next year, near Cowpens, by gen. Morgan, with a smaller force. He was with Cornwallis till the end of the war. He was elected to parliament in 1790, and made major-gen. in 1817. He wrote a *History of the Campaigns of 1780 and 1781 in the Southern Provinces of North America*.

TARN, a department in the s. of France, bounded on the n. by the departments of Aveyron and Tarn-et-Garonne, receives its name from the river Tarn. Area, 2,216 sq. m.; pop. 76,359,232. The surface is in general elevated, and in the s. and s.e. are the *montagnes Noires* and the *monts de l'Espinois*, branches of the *Cévennes*. The rock of Montalet, the principal summit, is 4,430 ft. high. Wooded mountains, vine-clad hills, beautiful valleys, and fertile or grass-producing tracts, are the principal features of the landscape. The chief river is the Tarn, an affluent of the Garonne (q.v.), and which has a westward course of 200 miles. A fifth part of the surface is covered with forests, chiefly of oak and beech. The department is for the most part agricultural, and the most improved methods are in use. Eleven million gallons of wine are made in average years. Tarn is divided into four *arrondissements*: Albi, Castres, Gaillac, and Lavaur. Albi is the capital.

TARN-ET-GARONNE, a small department in the s. of France, bounded on the s.e. by the department of Tarn. Area, 1435 sq.m.; pop. '76, 221,364. The principal river is the Garonne, which flows n.w., and its affluents, the Tarn and Aveyron. The surface is marked by plateaux, about 1000 ft. in average altitude; the highest hills do not rise above 1600 feet. The climate is beautiful, healthy, and temperate. Cereals are raised in great quantities. Of wine, 11,000,000 gallons are produced. The department is divided into the three arrondissements of Montauban, Castelsarrasin, and Moissac. Montauban is the capital.

TARNOPOL, a t. of Austria, in Galicia, charmingly situated on the left bank of the Sered, 80 m. e.s.e. of Lemberg. Agriculture employs the great mass of the inhabitants, and the horse market held here periodically is the most important in Galicia. Horse-races also take place. Pop. 20,000.

TARNOW, a t. of Austrian Galicia, near the right bank of the Dunajec, a navigable tributary of the Vistula, and 49 m. e. of Cracow by the Vienna and Lemberg railway. It is the seat of a Catholic bishop, contains a theological college, and a beautiful cathedral, in which are numerous monuments of marble, surmounted by statues, enriched with *bassi rilievi*, and rising to from 60 to 70 ft. in height. Several industries are actively carried on, and there is a good general trade. Pop. (including suburbs) 21,800.

TARPAULIN, a large sheet of the coarsest kind of linen or hempen cloth, saturated with tar to render it waterproof. It is used for covering loaded wagons, the hatchways of ships, and similar things, as a temporary protection from wet.

TARPEIAN ROCK (Lat. *Rupes Tarpeia*, or *Mons Tarpeius*), the name originally applied to the whole of the Capitoline hill (see **CAPITOL**), but latterly confined to a portion of the southern part of the hill, the following being the legend commonly related in connection with it. In the time of Romulus, Tarpeia (a vestal virgin), the daughter of Sp. Tarpeius, governor of the Roman citadel on the Capitoline, covetous of the golden ornaments on the Sabine soldiery, and tempted by their offer to give her what they wore on their left arms, opened a gate of the fortress to the Sabine king, Titus Tatius, who had come to revenge the rape of the Sabine women. "Keeping their promise to the ear," the Sabines crushed Tarpeia to death beneath their shields, and she was buried in the part of the hill which bears her name. Subsequently it was not unusual for persons condemned on the charge of aspiring to restore the monarchy, or of treason to the state generally, to be hurled from the Tarpeian rock—e.g., the famous Manlius, the savior of the capitol during the invasion of the Gauls.

TARQUINIUS, the family name of two kings of Rome, with whose history, or rather with the legends regarding whom, the fortunes of the city are closely interwoven. The story goes that Demaratus, a Corinthian noble, emigrated from Greece, and settled at Tarquinii, in Etruria, where he married an Etruscan wife, by whom he had two sons, Aruns and Lucumo. Aruns died during his father's lifetime, but Lucumo married into one of the noblest Etruscan families. His wife, named Tanaquil, was a bold, ambitious and wise woman. By her advice, Lucumo resolved to go to Rome. He set out, accompanied by a large train of followers, and as he approached the Janiculum, an eagle swooped down, and snatching off his cap, carried it up to a great height, then descending, placed it on his head again. Tanaquil, who was deeply skilled in the science of augury, prophesied from this omen the highest honors for her husband, who was hospitably received at Rome, and soon after admitted to the rights of citizenship, whereupon he took the name of L. Tarquinius, or, according to Livy, L. Tarquinius Priscus. The Roman monarch, Ancus Marcius, appointed him guardian of his children; and on the death of the former, the senate and the citizens unanimously elected him to the vacant throne. His reign was a glorious one. Against the Latins, Sabines, and (according to Dionysius) the Etruscans, he waged successful war, forcing the whole of the twelve sovereign cities of Etruria to recognize his supremacy, and do him homage. But the works that he executed at home are even more renowned than his exploits abroad. To L. Tarquinius Priscus (*Priscus* is commonly translated the "elder;" but Niebuhr objects to this translation as involving an anachronism, and notices the fact that *Priscus* is a common cognomen among the Romans) are ascribed the construction of the magnificent *Cloaca*, or sewers (see, however, **CLOACA MAXIMA**), which remain uninjured to this day; the laying out of the circus Maximus and the Forum; the institution of the great or Roman games; and (some say) the building of the Capitoline temple (see **CAPITOL**). The legend also represents him as effecting certain political and sacerdotal changes. See **ROME**. Tarquinius was assassinated after a reign of 38 years, at the instigation of the sons of Ancus Marcius, who considered themselves as best entitled to the throne, and dreaded lest he should use his influence to get his favorite and son-in-law, Servius Tullius, chosen as his successor. But their crime did not avail them, for, through the dexterity of Tanaquil, Servius was elected to the vacant throne, and signalized himself not only by his military exploits, but also by great organic changes in the Roman constitution (see article **ROME** for an account of the "Servian reform"). Tarquinius left two sons, L. Tarquinius Superbus and Aruns, both of whom married daughters of Servius Tullius; and two daughters, one of whom married Servius Tullius himself and the other M. Brutus, by whom she became mother of L. Brutus, first consul of the Roman republic.

L. TARQUINIUS SUPERBUS, son of the preceding, having murdered his father-in-law, Servius Tullius, at the instigation of his wife, is represented in the legend as audaciously usurping the vacant throne; but as the whole drift of his legislative policy was to abolish the reforms of Servius, there can be little doubt that the real significance of this part of his career lies in the fact that it indicates a successful reaction, on the side of the patricians, against the more liberal and progressive policy of the preceding age. That the younger Tarquinius, at least, is a historical character, seems to be pretty generally allowed. The incidents of his career are so numerous and coherent, and the impress of his name and character is so deeply stamped on the national memory, that he cannot be regarded as a wholly imaginary personage. Analyze the story how we may, there will always remain a residuum of insoluble fact, not essentially at variance with the character of the tragic tradition. As far as we can gather from the ancient annals, the usurpation of Tarquinius was probably achieved by the help of an enterprising section of the nobles, who clung tenaciously to their privileges, and could not endure the constitutional recognition of the *plebs*. It does not appear that the whole of the senators connived at or even approved of Tarquinius's procedure. We are expressly told that he drove numbers of those whom he mistrusted into exile: in other words, he persecuted and banished the adherents of the Servian policy of conciliation. Like a Turkish tyrant, he surrounded himself with a body-guard—another indication of the original insecurity of his position, and strengthened himself by foreign alliance, marrying his daughter to Octavius Mamilius, prince of Tusculum. By means of subtle and unscrupulous intrigues he obtained or consolidated the Roman hegemony in Latium; offered sacrifice in the name of all the Latins at the Alban mount; fused the contingents of the latter with the Roman legion: put to death as traitors such of their chiefs as opposed him (e.g., Turnus Herdonius); and, at the head of the combined forces, penetrated into the Volscian marshes, and, subdued the natives. On his return he completed the building of the capitol, which the elder Tarquinius had begun, and deposited in the vaults the Sibylline books he had curiously acquired. See SIBYL. He next conquered the town of Gabii (where many of the banished nobles had found shelter), through an elaborate stratagem, in which his son Sextus played the principal part. But his lavish expenditure both in war and peace necessitated the imposition of heavy taxes, and murmurs of discontent were heard among the people. The patience both of plebs and patricians was beginning to give way. Coincident with this state of things a fearful omen was beheld: from the altar in the royal palace crept forth a serpent, and devoured the entrails of the victim. Tarquinius sent two of his sons, Titus and Aruns, to Delphi to consult the oracle. They were accompanied by their cousin, L. Junius Brutus (q.v.), who had long feigned himself a fool in order to save his life, for Tarquinius had killed his father and brother in order to possess himself of their great wealth. On their return they found that the king had opened war upon the Rutuli, and was besieging Ardea, whereupon they joined the Roman camp. Here occurred, between Sextus and Collatinus, the famous dispute about the virtues of their respective wives, which led to the rape of Lucretia. The details of this legend are so familiar that it is unnecessary to recount them. Suffice it to say that it roused such a storm of indignation that the people of Collatia (where the shameful deed was done) rose in arms, and renounced their allegiance to Tarquinius. Brutus carried the news to Rome, and the senate, fired with a righteous anger, deposed the tyrant; finally, the army before Ardea also revolted. Tarquinius and his sons were obliged to flee, and an aristocratic republic was constituted at Rome. Three different attempts were made to restore Tarquinius by force: first, by his own Etruscan kinsmen of Tarquinii; second, by Lars Porsena (q.v.) of Clusium; and third, by his son-in-law, Octavius Mamilius, "prince of the Latian name," all of which, according to the legend, failed; and at length Tarquinius, utterly baffled and beaten, retired to Cumæ, where he died, a wretched and childless old man, for all his sons had met death before him.

TARRAGON. See ARTEMISIA.

TARRAGONA, a province in n.e. Spain, part of the ancient division of Catalonia or Cataluna, lying on the Mediterranean and adjoining the provinces of Teruel, Saragossa, Barcelona, Castellon, and Lérida, drained by the Ebro and a few streams of little importance; 2,451 sq. m.; pop. '70, 350,395. There is much mountainous surface, the Prades range crossing the province from n. to s.; but the valleys and lower slopes are very rich in soil and covered with vineyards, from which excellent wine is produced; other exports are brandy, cork, silk, velvet, and woolen and cotton goods. Capital, Tarragona.

TARRAGONA, a sea-port of Spain, chief city of the modern province of the same name, stands on the Mediterranean shore, at the mouth of the Francolí, 60 m. w. of Barcelona. It consists of two portions—the upper (the ancient) and the lower (the modern) towns. The former stands on a hill 720 ft. high, and is girdled with ramparts. The lower town, completely separated from the higher by a line of works, is regular and open, and is defended by two forts. The beautiful cathedral, in Gothic and Norman, and which dates from the middle of the 12th c., is the principal edifice. There is an interesting antiquarian museum, rearranged in 1868. Brandy distilling and the manufacture of wines and olive oil are the chief industries. The harbor is safe for the vessels that visit Tarragona. Pop. 19,500.

Tarragona, called by the Romans *Tarraco*, was founded by the Phenicians (who called it *Tarchon*, citadel), and afterward became the capital of the Roman province of *Tarraconensis*. Among the Roman antiquities are the remains of an amphitheater, which has been used as a quarry; a magnificent aqueduct, 96 ft. high and 700 ft. long—still in use—and near the town the tower of the Scipios, much decayed. *Tarragona* was taken and cruelly sacked, in June, 1813, by the French under Suchet.

TARRANT, a co. in n.w. Texas; 900 sq.m.; pop. '80, 24,678—23,792 of American birth; 2,187 colored. Co. seat, Fort Worth.

TARRYTOWN, a village of N. Y., on the e. bank of the Hudson river, 27 m. n. of New York city. It is beautifully situated on a lake-like expansion of the river, called the Tappansee; surrounded with fine scenery, and filled with elegant residences. It has 6 churches and 4 academies, and is noted as the scene of the capture of Major André. Pop. 3,500.

TARSHISH, probably the same as *Tartessus*, a city and emporium of the Phenicians in Spain, somewhere near the mouth of the Guadalquivir. It is frequently mentioned in Scripture, notably so in connection with the prophet Jonah, who took ship for Tarshish, when he sought to "flee from the presence of the Lord."

TARSIA-WORK, a beautiful kind of marquetry made in Italy. It is produced by inlaying pieces of colored wood so as to represent figures and landscapes. That of Sorrento is very celebrated; and lately, many fine pieces of this work have been made in Perugia. It is usually applied to the decoration of cabinet-work.

TARSUS, anciently the chief city of Cilicia, and one of the most important in all Asia Minor, situated on both sides of the navigable river Cydnus, in the midst of a beautiful and productive plain, and about 18 m. from the sea. It was a great emporium for the traffic carried on between Syria, Egypt, and the central region of Asia Minor. In the time of the Romans, two great roads led from Tarsus, one n. across the Taurus by the "Cilician Gates," and the other e. to Antioch by the "Amanian" and "Syrian Gates." Tarsus, judging from its name, was probably of Assyrian origin; but the first historical mention of it occurs in the *Anabasis* of Xenophon, where it figures as a wealthy and populous city, ruled by a prince tributary to Persia. In the time of Alexander the Great, it was governed by a Persian satrap; it next passed under the dominion of the Seleucidæ, and finally became the capital of the Roman province of Cilicia. At Tarsus, Anthony received Cleopatra, when she sailed up the Cydnus, with magnificent luxury, disguised as Aphrodite. Under the early Roman emperors, Tarsus was as renowned for its culture as for its commerce, Strabo placing it, in respect to its zeal for learning, above even Athens and Alexandria. It was the birthplace of the apostle Paul, who received the greater part of his education here; and here the emperor Julian was buried. Gradually, during the confusions that accompanied the decline of the Roman and Byzantine power, it fell into comparative decay; but even yet, it is—under the name of *Tarsus* or *Tarsus*—the most considerable place in the s.e. of Asia Minor, has a pop. of 30,000 (in winter); and exports corn, cotton, wool, copper, gall-nuts, wax, goats, hair, skins, hides, etc.

TARTAN, or **PLAID**, a pattern woven in cloth, in which bands of different colors are woven or printed side by side, both the warp and weft way of the material, thus giving the well-known checkered pattern. This is probably the oldest pattern ever woven; at all events, the so-called shepherd's plaid of Scotland is known to have a very remote antiquity among the eastern nations of the world. The plaid pattern admits of a very great variety of modifications, by the introduction of different colors, and by varying the amount of each color employed. These colored plaids were in great favor in the Highlands of Scotland, where each clan wore a particular kind as its distinctive dress.

TARTAR, a mixture of bitartrate of potash and tartrate of lime (see **TARTARIC ACID**), is a deposit formed from wine, and known in its crude form as argol (q.v.). About 900 tons annually of this substance are imported into Great Britain, from the chief wine-producing countries of Europe and the cape Good Hope.

The word *Tartar*, which gives the name to tartaric acid, is derived from the Greek *Tartaros*, hell. "It is called *Tartar*," says Paracelsus, "because it produces oil, water, tincture, and salt, which burns the patient as Tartarus does."

TARTAR, CREAM OF. See **TARTARIC ACID**.

TARTAR, FOLIATED EARTH OF, an old name for acetate of potash, in consequence of the foliated satiny masses in which that salt occurs.

TARTAR, SOLUBLE, a term applied by some chemists to neutral tartrate of potash, and by others to borotartaric acid. See **TARTARIC ACID**.

TARTAR OF THE TEETH is a deposit of salts of lime and organic matter from the saliva, and usually occurs most abundantly on the inferior incisors. If it is suffered to accumulate, it causes inflammation and absorption of the gum, and gradual loosening of the teeth. The accumulating of this substance may usually be prevented if due attention is paid to the cleaning of the teeth. "The teeth," says Dr. Druitt, "should be cleaned at least twice a day with a soft tooth-powder (precipitated chalk is best) and a little soap. The hairs of the tooth-brush should be soft, and not too closely set, so that

they may penetrate the better into the interstices of the teeth." When the tartar has accumulated to any extent, it must be removed by the *scaling instruments* of the dentist.

TARTARIC ACID. Ordinary tartaric acid, $C_4H_4O_6 \cdot 2H_2O$, is usually seen in the form of colorless, transparent, oblique, rhombic prisms, which are not affected by the action of the air, have an agreeable acid taste, and are soluble in water and alcohol. The crystals when gently warmed become strongly electric, the opposite sides of the crystals exhibiting the opposite forms of electricity. On heating tartaric acid to about 340° , it fuses; and at a slightly higher temperature it becomes successively changed, without losing weight, into two metameric acids, *metatartaric* and *isotartaric* acids, the former of which is bibasic and the latter monobasic. At about 374° , two atoms of the acid lose one equivalent of water, and *tartralic acid*, $C_{16}H_8O_{20} \cdot 3H_2O$, is formed. If the same temperature be maintained a little longer, half the basic water is expelled, and *tartralic acid*, $C_{16}H_8O_{20} \cdot 2H_2O$, is formed; and finally, all the basic water is driven off, and *anhydrous tartaric acid*, or *tartaric anhydride*, $C_8H_4O_{10}$ (or $C_{16}H_8O_{20}$), remains in the form of a white porous mass insoluble in water, alcohol, or ether. If, however, it be allowed to remain long moist, it gradually becomes converted into crystallized tartaric acid. Finally, on distilling tartaric acid in a retort at a temperature of 400° and upward, it is decomposed into certain gases and empyreumatic oily matters, water, and acetic, pyruvic (or pyruaemic) and pyrotartaric acids.

Oxidizing agents, such as peroxide of lead or nitric acid, readily act upon tartaric acid, and convert it into formic and carbonic acids; and when fused with caustic potash, it splits up into acetic and oxalic acids. It is one of the strongest of the organic acids.

This acid occurs abundantly in the vegetable kingdom both in the free and combined state. It is found as a free acid in tamarinds, grapes, the pine-apple etc.; and in combination with potash and lime in tamarinds, grapes, mulberries, and the unripe berries of mountain-ash, and in small quantity in the juice of many other vegetables. It is, however, from argol (q.v.), a product of the fermentation of grape-juice, that the tartaric acid of commerce is obtained. The details of the process may be briefly described as follows: argol, or crude bitartrate of potash, is dissolved in boiling water, and chalk is added as long as effervescence occurs. An insoluble tartrate of lime is precipitated, and tartrate of potash remains in solution. This tartrate of potash is converted by the addition of chloride of calcium, into insoluble tartrate of lime and soluble chloride of potassium. The tartrate of lime obtained by these two operations, if treated with sulphuric acid, readily yields free tartaric acid in solution, with sulphate of lime as a precipitate. The filtered liquid, when cooled and evaporated, yields tartaric acid in crystals.

Tartaric acid is used in large quantity by calico-printers and dyers for the removal of certain mordants, and is much employed in medicine in the preparation of effervescing draughts and for other purposes.

Tartaric acid being bibasic, can form both acid and normal (or neutral) salts, according to the two general formulæ, MO, HO, \bar{T} , and $2MO, \bar{T}$, when M signifies any metal, and \bar{T} is used as a symbol for anhydrous tartaric acid, $C_4H_4O_6$. The normal salts may contain (1) two similar or (2) different protoxides, or (3) a protoxide and sesquioxide, or (4) a protoxide and a teroxide; as, for example—(1) Tartrate of potash, $2KO, \bar{T}$; (2) Tartrate of potash and soda, or Rochelle salt, KO, Na, \bar{T} ; (3) Tartrate of potash and iron, KO, Fe, O_3, \bar{T} ; (4) Tartrate of potash and antimony, or tartar emetic, $KO, SbO_3, \bar{T} + Aq$. The tartrates are for the most part formed by partially or entirely saturating the free acid with an oxide or carbonate, or in the case of neutral tartrates containing two oxides, by saturating a solution of the bitartrate of one oxide with the other oxide. The most important tartrates are the following:

Tartrate of potash, $2KO, \bar{T}$, a soluble salt, which crystallizes with difficulty, and is formed in preparing tartaric acid from *bitartrate of potash*, KO, HO, \bar{T} . This salt is prepared from argol by extraction with boiling water, which dissolves about one-sixth of its weight. As it is much more insoluble in cold water, of which it requires 240 parts, it crystallizes readily as the hot solution cools. The snowy white rhombic prisms which are thus deposited constitute *cream of tartar*. When heated to redness in a covered crucible, a charred mass, consisting of carbonate of potash and charcoal in a fine powder, remains, and is used in the laboratory for reducing operations under the title of *black flux*; and if cream of tartar is deflagrated with twice its weight of niter, *white flux*, also a reducing agent, consisting solely of carbonate of potash, is obtained. *Tartrate of potash and soda* has been already described in the article ROCHELLE SALT. *Tartrate of potash and iron*, or *ferrum tartaratum*, $KO, Fe_2O_3, \bar{T} + Aq$, and *tartrate of ammonia and iron*, or *ammonio-tartrate of iron*, $H_4NO, Fe_2O_3, \bar{T} + 4Aq$, although the latter is not included in the pharmacopœia, are excellent medicinal preparations of iron. For the method of preparing them, the reader is referred to *Neligan's Medicines*, 6th ed. p. 658, etc. They occur in the form of brilliant, semi-transparent, reddish-brown scales, and are soluble in about their own weight of water at 60° . *Tartrate of potash and boron*, known also as *soluble tartar* (although the term has also been applied to tartrate of potash),

or soluble cream of tartar, $\text{KO}, \text{BO}_3, \bar{\text{T}}$, has been employed medicinally, but is not now used. *Tartrate of antimony and potash*, known also as *tartarized antimony* and *tartar emetic*, $\text{KO}, \text{SbO}_3, \bar{\text{T}}_{10} + 2\text{Aq}$, is one of the most valuable articles in the whole *Materia Medica*. This salt, obtained by a process which is given in the pharmacopœia, occurs in the form of square prisms, which are soluble in about 15 parts of cold water and in 2 parts of boiling water. This salt is somewhat efflorescent, and when dried at 212° loses all its water of crystallization; its solution slightly reddens litmus, throws down an orange-colored sulphide of antimony, if a current of sulphureted hydrogen is passed through it, and has a very peculiar nauseous, metallic taste.

There is no very delicate test for tartaric acid. Its presence in a moderately strong solution may be detected by the addition of acetate of potash, when a sparingly soluble bitartrate is soon separated, especially if the mixture be well stirred. All the tartrates on charring emit a peculiar odor resembling that of burned sugar.

A remarkable metameric modification of tartaric acid is known as *racemic* or *paratartaric acid*, $2\text{HO}, \text{C}_6\text{H}_4\text{O}_{10} + 2\text{Aq}$. It is a frequent associate of tartaric acid, but is especially abundant in the grapes of the Vosges district. While in most respects it exhibits a close resemblance to tartaric acid (the two acids having the same composition, yielding, when exposed to heat, the same products, and their salts corresponding in the closest manner), it may be distinguished and separated from it by the following points of difference. It crystallizes more readily from solution; it contains two equivalents of water of crystallization; it is less soluble in alcohol; and the racemate of lime is soluble in hydrochloric acid, and is precipitated unchanged on adding ammonia. Its most important difference, however, is, that its solution does not rotate the plane of polarization, while a solution of ordinary tartaric acid exerts a well-marked right-handed rotation.

The brilliant researches of M. Pasteur on the optical and chemical properties of tartaric and racemic acids, have opened up a new and most important field of investigation in relation to the molecular composition of organic bodies. We shall give the briefest possible abstract of his remarkable discoveries, and must refer for fuller information to his numerous memoirs in the *Comptes Rendus*, *Annales de Chimie*, and other French scientific journals. He has proved that racemic acid is a mixture of ordinary tartaric acid (to which, from its optical property, he applies the term *dextro-racemic acid*) and of an acid which produces left-handed rotation, to which he gives the name *levo-racemic acid*. (These acids are also known as *dextro-tartaric* and *levo-tartaric acids*.) He found that, by saturating racemic acid with soda and ammonia, and allowing this solution to crystallize slowly, two varieties of crystals are obtained, which may be distinguished by their form, in the same way as the image and the reflection of the image in a mirror differ; or as right-handed and left-handed. If the two kinds of crystals are separated, and then dissolved, each solution is found to act powerfully on polarized light, but in opposite directions. On separating these acids from their bases, and mixing equal parts of concentrated solutions of each, racemic acid is again formed, which exerts no action on a polarized ray. M. Pasteur has subsequently made the discovery, that racemic acid may be artificially produced by the action of heat upon certain compounds of tartaric acid (such as tartrate of cinchonine or tartaric ether), which are capable of resisting a high temperature. The formation of racemic acid in this way is accompanied by the production of another modification of tartaric acid, which he calls *inactive tartaric acid*, which, like racemic acid, has no action on polarized light, but unlike it, cannot be resolved into dextro and levo-racemic acids.

Tartaric acid and the tartrates, in their relation to medicine, are of considerable importance. Pure *tartaric acid*, in small doses diluted largely with water, forms a good refrigerant drink in febrile and inflammatory affections, and is much employed for this purpose in hospitals, etc., as being cheaper than citric acid. It has been stated that persons addicted to habitual drunkenness have been reclaimed by the following treatment: A few crystals of the acid are dissolved in two small tumblers of water, and taken in the morning fasting, an hour intervening between the tumblers. The painful feeling of sinking and craving of the stomach, of which such persons usually complain, is said to be removed by these acid draughts. Under the name of *acidulated drops*, lozenges composed of this acid, sugar, and oil of lemons are largely employed in mild sore throats and colds. The principal medical use, however, of tartaric acid is in the preparation of effervescent draughts, when added to alkaline carbonates; and in the composition of scidlitz powders (q.v.). *Tartrate of potash* is a mild but efficient purgative in doses of from two to six drams, which is perhaps hardly so much used as it deserves. In passing through the system it becomes converted into carbonate, and thus renders the urine alkaline. *Acid tartrate*, or *bitartrate of potash*, commonly known as *cream of tartar*, in full doses, acts as a sharp purgative, but is generally prescribed with some of the milder vegetable cathartics. When administered in small repeated doses (from a scruple to a dram), in a large quantity of water, it largely increases the secretion of urine, and is consequently of great service in dropsy. It may be agreeably given in either of the following forms: (1) *Imperial*, which is prepared by dissolving a dram of cream of tartar in a pint of boiling water, and flavoring with lemon-peel and sugar. In incipient dropsy, a couple of tumblers of this mixture, with half a glass of good holland

in each, are strongly recommended by Dr. Neligan as an after-dinner drink. The proportion of cream of tartar to the pint of water may be gradually increased to two drams. (2) *Cream of tartar whey* is prepared by boiling 100 grains of the salt in a pint of new milk, and removing the curds by straining. Either of these drinks may be safely taken to any extent agreeable to the patient. *Tartrate of iron and potash*, the *ferrum tartaratum*, or *tartarated iron*, of the pharmacopœia, is a mild chalybeate tonic, which, in consequence of its somewhat sweet taste, is well adapted for children. It occurs in transparent scales of a deep garnet color, is soluble in water, and sparingly soluble in spirit. The dose varies from 5 grains to a scruple, three times a day, either given with honey or treacle, or dissolved in some aromatic water. The *wine of iron* (*vinum ferri* of the *Pharm. Brit.*) consists of sherry with tartrated iron in solution. Each dram ought to contain one grain of the salt. The *tartrate of iron and ammonia*, or *ammonio-tartrate of iron*, closely resembles in its action the tartrate of iron and potash. Although not in the *Pharm. Brit.*, it is "an excellent preparation of iron, void of all astringency. Its not disagreeable taste, its solubility in water, its compatibility with the alkaline carbonates, and the permanency of its composition, give it an advantage over most of the other preparations of iron. It is peculiarly suited as a tonic for those derangements of the uterine organs in which ferruginous salts are indicated,"—Neligan's *Medicines*, 6th ed. p. 645. The dose is from 5 to 8 grains, and it may be prescribed in the form of powders, pills, or solution; or made into a bolus with honey. *Tartar emetic*, in doses of from $\frac{1}{12}$ to $\frac{1}{2}$ of a grain, frequently repeated, acts as a diaphoretic or sudorific; nausea sometimes accompanies the diaphoresis, but it has the advantage of increasing the tendency to perspiration. The addition of the compound tincture of lavender tends to prevent the supervention of vomiting. Tartar emetic in these small doses is of great service in febrile disorders, in the hæmoptysis of phthisis, in obstinate cutaneous diseases, etc. *Antimonial wine* consists of sherry holding tartar emetic in solution in the proportion of two grains to the ounce. The dose, to produce a diaphoretic action is 20 or 30 minims every hour. If we require an expectorant action—as in acute pneumonia or bronchitis—the salt should be given in still smaller doses, as from $\frac{1}{16}$ to $\frac{1}{8}$ of a grain. Tartar emetic, in doses of two or three grains, dissolved in water, acts as a powerful emetic, and at the same time produces much nausea and depression, and not unfrequently purging. The vomiting seldom occurs till about 20 minutes after the draught has been taken. If tartar emetic is thus given at the commencement of febrile or inflammatory affections, it will often cut short the impending disease. With this view it is employed in continued fever, croup, whooping-cough, etc. It used to be given to relax the muscular system, in cases of strangulated hernia and dislocation; but chloroform is far better for these objects. In cases of poisoning it is inferior to sulphate of zinc. It is expedient to take the emetic dose in parts, as too powerful an effect is thus prevented. Two grains, which are generally sufficient, must be dissolved in eight ounces of water, of which a quarter should be taken every ten minutes till vomiting ensues. The patient should walk gently about his room between the doses. If a large dose (of one, two, or even three grains) be repeated every second hour, the nausea, vomiting, and purging (which often follows a full dose) cease after two or three such doses, and the main action seems to be exerted in depressing the circulation and lowering the pulse. Hence, tartar emetic given in this way is a direct sedative or contra-stimulant, and is of great service in pneumonia and pleurisy. "As a contra-stimulant," says Neligan, "tartar emetic is given in doses of from half a grain to two grains every hour or second hour, dissolved in one or at most two ounces of orange-flower water. The first dose or two should not exceed half a grain, and the patient should not be permitted to drink, so as, if possible, to avoid the production of vomiting. When once a tolerance of the medicine is produced in the system, the quantity taken may be rapidly increased."—*Op. cit.*, p. 418. Lastly, tartar emetic, when applied to the skin, produces a crop of pustules, which ulcerate, and discharge purulent matter. In consequence of this property, tartar emetic, either in the form of ointment or of saturated solution, is often employed as a counter-irritant in various affections of the viscera of the chest and abdomen, in diseases of the joints, etc. The *ointment* is applied by rubbing about half a dram on the skin night and morning. In two or three days pustules begin to appear, when the further application of the ointment should be temporarily suspended. The saturated solution is a cleaner preparation than the ointment, and acts more speedily. It is applied by means of pledgets of lint soaked in it. Tartar emetic, in excessive doses, or in small repeated doses, acts as an irritant poison. Dr. Taylor has reported 37 cases of poisoning by this agent, of which 16 were fatal. The smallest fatal dose was in a child *three-quarters of a grain*, and in an adult *two grains*, but in the last case there were circumstances which favored the fatal action of the poison. The symptoms occurring in chronic poisoning by this salt are "great nausea, vomiting of mucus and liquids, great depression, watery purging, followed often by constipation of the bowels, small, contracted, and frequent pulse, loss of voice and muscular strength, coldness of the skin, with clammy perspiration, and death from complete exhaustion." A considerable number of cases are on record in this country in which murder has been perpetrated by the slow action of tartar emetic. The most important of them are referred to by Dr. Taylor in his *Medical Jurisprudence*, pp. 146 and 250, to which must be added the Pritchard case in Glasgow, 1865. The *Pharmaceutical Journal* for Oct., 1865, contains direc

tions, by Messrs. T. and H. Smith, of Edinburgh, for preparing an antidote to be prescribed after a large dose of tartar emetic has been taken. The ingredients are solution of perchloride of iron and calcined magnesia.

TARTARS, or, more properly, **TATARS**, was originally a name of the Mongolic races, but came to be extended to all the tribes brought under Mongolic sway by Genghis Khan and his successors, including Tungusic and Turkic races. The term is therefore not to be considered as ethnological, though all, or almost all, the peoples included under it, in its widest sense, belong to the Turanian family, but is rather to be understood in the same sense as the term "Franks" used by Mohammedans. In the classification of languages, Tartaric has become the distinctive name of that class of Turanian languages of which the Turkish is the most prominent member, while the Mongolic form a separate class. See **TURANIAN LANGUAGES**.

TARTARUS (Gr. *Tartaros*; the name is probably onomatopœic, the reduplication being designed to express something terrible or disagreeable, like *Barbaros*, *Karkaron*, and many other words), according to Homer, is a deep and sunless abyss, as far below Hades as earth is below heaven, and closed in by iron gates. Into Tartarus, Zeus hurled those who rebelled against his authority, as e.g., Kronos and the Titans. Afterward the name was employed sometimes as synonymous with Hades or the under-world generally, but more frequently to denote the place where the wicked were punished after death—lowest hell, in fact. A noticeable feature about these punishments is their congruity with the nature of the offenses perpetrated. See **HEAVEN** and **HELL**.

TARTARY (properly **TATARY**) is the name under which, in the middle ages, was comprised the whole central belt of central Asia and eastern Europe, from the sea of Japan to the Dnieper, including Manchuria, Mongolia, Chinese Turkestan, Independent Turkestan, the Kalmuck and Kirghis steppes, and the old khanates of Kasan, Astrakhan, and the Crimea, and even the Cossack countries; and hence arose a distinction of Tartary into European and Asiatic. But latterly the name Tartary had a much more limited signification, including only that tract bounded on the n. by Siberia, and on the s. by China and Thibet, along with Independent Turkestan; and at the present day, many writers apply it as a synonym for Turkistan (q.v.).

TARTINI, GIUSEPPE, 1692-1770; b. Pirano, Italy; received lessons in music, violin-playing, and fencing; studied law; married privately at Padua, and to avoid arrest by the bishop fled to a convent, where for two years he gave himself to the study of the violin, receiving lessons in composition from father Boemo, the organist of the convent; appointed chief violinist of the chapel of St. Anthony at Padua, 1721; established, 1728, at Padua a violin school of great celebrity. He left in MS. 48 violin sonatas, 1 trio, 127 concertos, besides his published works. *Sonate du Diable*, or *Tartini's Dream*, he considered his best composition.

TARTRALIC ACID and **TARTRELIC ACID**. See **TARTARIC ACID**.

TARTUFE, the name of the chief character in Molière's most celebrated comedy, which has become a synonym in all languages for a hypocritical pretender to religion. The original of the character was most probably a certain abbé de Roquette, a parasite of the prince de Conti. The name is said to have suggested itself to Molière on the occasion of a visit to the papal nuncio, where he saw the pious and solemn countenances of the nuncio's courtiers suddenly lighted up with ecstasie animation by the appearance of a seller of truffles—in Italian, *tartuffoli*. This play excited a greater commotion than perhaps any other production of the kind ever did. It was written in 1664; but before it was brought on the public stage, partial representations of it in private companies had made its character known, and raised the alarm of the priests, who believed themselves to be specially satirized therein. Uniting with the many enemies whom Molière had already made for himself by lashing physicians, fops, and fools of all kinds, they used every means in their power to prevent the public representation of the play. The archbishop of Paris threatened with excommunication all actors who should take any part in the performance, and even those who should only read it; and one dignitary went so far as to declare that Molière—whom he called a devil in human form—was deserving of the stake. It was not till 1669 that Molière succeeded in getting the play publicly acted in presence of Louis XIV.; and then it had an uninterrupted run for three months, to the great vexation of all hypocrites.

TARUDANT, a city in the province of Soos, Morocco; about 4 m. from the Soos river, and 150 m. s. w. from Morocco; pop. about 50,000. It is walled and defended by a citadel. Most of the houses have but one story, and the streets are narrow and crooked. The city is surrounded by a highly cultivated country, and itself contains many groves and gardens. Its chief manufactures are of copper, leather and dyes.

TASCHEREAU, ELZÉAR ALEXANDRE, b. Quebec, 1818; educated at the Quebec seminary. He entered the Roman Catholic priesthood in 1842; was for some time professor of mental philosophy, and superior in the Quebec seminary, and became professor of canon law at Laval university in 1856. He became administrator of the Quebec diocese in 1870, and archbishop of Quebec in 1871.

TASHKAND, till recently a t. of Independent Turkistan, but now in the possession of Russia, is situated in the khanate of Khokan, 92 m. n.n.w. of Khokan, the capital on the n. bank of the Saralka, a small feeder of the Djirhik river, an impetuous torrent, which empties itself into the Sir-Daria. It is the chief commercial town in the district, is the center of the transit-trade between Bokhara, Khokan, and Chinese Tary, and has extensive trading relations with Orenburg and Petropavlovsk. Like most of the cities of central Asia, it stands in a fertile plain. It covers a large tract of ground, being said to extend 10 m. in one direction and 5 in another, and is protected by a high wall of sun-dried bricks. Within the walls are numerous gardens and vineyards, interspersed among the houses; the houses themselves are built of mud, and thatched with reeds. The streets are narrow and dirty. The chief buildings are the castle (which is fortified), various mosques, colleges, old temples, and a bazaar. The chief manufactures are gunpowder, silk and cotton goods, and iron. According to a census taken in 1871, the pop. amounted to 78,125. Tashkand is also important in a military point of view, and, mainly for this reason, had been long coveted by Russia. The Russians, who captured it in 1854, and retained it for a short time, finally took possession of it in 1865, having in the mean time made great advances in central Asia. The petition of the inhabitants, that they might be received as Russian subjects, was granted in 1866; and since then it has been governed by a kind of municipal board, the president being a Russian officer, and the members chosen by the townspeople.

TASMAN, ABEL JANSSEN, b. Hoorn, n. Holland, about 1600; was sent, 1642, by Van Diemen, governor-general of the Dutch East India company to explore New Holland, and on Nov. 24 discovered the island which he called Van Diemen's Land (now Tasmania). After a voyage of 10 months, in which he discovered New Zealand, the islands of the Three Kings, the Friendly, and Feejee islands, he returned to Batavia. He made a second voyage to New Guinea and New Holland, 1644; but we have no details of it, as he never returned. He published an account of his first voyage.

TASMANIA, formerly VAN DIEMEN'S LAND, a considerable island in the South Pacific ocean, between the parallels of 40° 40' to 43° 40' s. lat., and between 144° 30' to 148° 30' e. long., lying to the s. of, and separated from Australia by Bass's strait. Its greatest length, from cape Grim, on the n.w., to cape Pillar on the s.e., is 240 m.; and its greatest breadth from e. to w., 200 m.; its area, including the adjacent islands, about 26,300 sq. miles. The capital is Hobart Town, with a pop. of 20,000, situated at the base of Mt. Wellington, on the western shore of the estuary of the river Derwent. The second chief town is Launceston, with a pop. of 10,668, situated at the head of the estuary of the Tamar, formed by the junction of the North and South Esk rivers. In the year 1854 the population consisted of—males, 30,613; females, 28,261; total, 64,874. In 1874, males, 55,117; females, 49,059; total, 104,176. Total pop. in Dec., 1877, 107,104. Hobart Town and Launceston are connected by the electric telegraph, and by an excellent macadamized road, 121 m. in length, from which good roads branch off. In 1878 there were 630 m. of telegraph. The first line of railway, 45 m. in length, was opened in 1871, uniting Launceston with Deloraine: there are in all about 180 m. of railway.

Physical Features.—The south-eastern coast of Tasmania is deeply indented by the estuaries of the Derwent and Huon, Storm bay, the inlet of Pitt Water, and Frederick Henry bay. The last is protected on the s.e. by Tasman's peninsula, reserved as a penal settlement for the colony. The chief indentations on the w. coast are Macquarie harbor (formerly a penal settlement, but now uninhabited), and Port Davey. On the e. coast are Oyster bay, between Freycinet's peninsula and the mainland; and Spring bay, sheltered on the e. by Maria island. On the n. coast, besides the estuary of the Tamar, there are numerous smaller harbors and rivers, accessible to vessels of from 30 to 300 tons. The chief of these are Circular Head, Port Sorell, and the rivers Mersey, Forth, Leven, Don, and Inglis. The scenery is of a bold mountainous character, varied by deep narrow valleys, extensive undulating tracts of country, and open plains of limited extent. Among the principal mountains are Ben Lomond (5,002 ft.), Cradle mount (5,069 ft.), Ironstone mount (4,736 ft.), Mt. Barrow (4,644 ft.), Mt. Wellington (4,166 ft.), with many others exceeding 4,000 ft. in height. Embosomed among the central mountains, at an average height of about 3,000 ft., are numerous lakes, with a united area of about 170 sq.m., which feed the greater part of the rivers draining the s.e. slope of the island. With the exception of the reclaimed lands, the basaltic plains, and limited tracts which are unfavorable to the growth of timber trees, the whole island is more or less densely wooded. The vast forests of the western portions of the n. and s. coasts are extensively utilized for timber, and in the former, the work of reclaiming the rich heavily-timbered lands is rapidly progressing. But the major part of the western half of the island is entirely uninhabited, its soil, climate, and inaccessible position offering little inducement to the settler.

Geology and Mineralogy.—The bed-rocks of the western districts, from Bass's strait to South-west cape, consist of vast bands of slates, schists, and quartz rock, belonging to the azoic or metamorphic series. Next to these come lower paleozoic slates, with conglomerates and dark compact limestones, the latter highly charged with Silurian fossils. Unconformably upon the upturned edges of these rocks lie upper paleozoic sandstones, mudstones, limestones, and conglomerates, also traversed by dikes and masses of green-

stone and basalt, and with these, reaching an altitude of 4,000 ft. above the sea-level. In the s.e. districts, from the South Esk river on the n. to the Huon on the s.w., the lower rocks are entirely absent, or concealed beneath the upper paleozoic beds. In the n.e. district, the lower rocks again make their appearance, associated with granite and greenstone, and occasionally traversed by dikes and veins of the true auriferous quartz. Here, again, they are overlaid by upper paleozoic rocks, extensively denuded, and exposing seams of coal from 2 ft. to 14 ft. thick, at various elevations. Tertiary rocks are sparingly distributed. At the mouth of the river Inglis, on the n. coast, are beds of a whitish free-stone, attaining in places a thickness of 120 ft., and containing recent shells, with extinct species of *irigoniu*, *terebratul*, *cyprea*, *rotula*, etc. Tertiary lignites are found in the sandy clays of the valleys of the Derwent and Tamar, with impressions of leaves of unknown trees and plants. Over the greater part of the basin of the South Esk, comprising an area of more than 1000 sq.m., extensive deposits of clays, sands, and quartz drift are met with. No distinct traces of glacial action have been observed; but the thick beds of gravel, and the boulders, which must have traveled many miles from their parent rock, afford evidence of some powerful transporting agency, and were probably deposited in their present sites by the action of icebergs slowly drifting northward at some period prior to the last general elevation of the land.

The igneous rocks are everywhere present in great variety. The islands of the Furneaux group in Bass's strait are chiefly of granite, and form the connecting links which join the n.e. angle of Tasmania to the great dividing range of eastern Australia. Gold has been found in many places, and the workings have for years given fair returns to a limited number of miners. In 1875, the quantity of gold produced was 3,010 ounces. Silver and antimony have been occasionally met with in the gold drifts, and very rich deposits of tin have begun to be worked at Mount Bischoff. In the six months ending June, 1877, 900 tons of tin ore were shipped. Copper occurs in thin veins, associated with galena, on the n. coast, near the river Leven, and galena has been found elsewhere in the primitive limestones. Red and brown hematites, containing a large percentage of iron, occur at various points on the n. coast, in large masses and lodes. Iron-works on an extended scale are now in operation; in 1874 the produce was 1400 tons. Coal is worked in several parts of the island, chiefly for local consumption. A large lode of bismuth was discovered in 1875. The older limestones yield fine varieties of marble, and excellent building stone is obtained from the greenstones, basalts, and paleozoic sandstones.

Botany.—The flora of Tasmania has been fully described in the botany of the antarctic voyages by Hooker and others. The majority of the species are common to Australia and Tasmania. Of those which are peculiar to the latter, many are limited to particular localities. The most widely diffused genera are the eucalypti and acacia, the former yielding the ordinary timber of the colony. The blue gum (*eucalyptus globulus*) reaches a height of 350 ft., with a corresponding girth. The blackwood (*acacia melanoxylon*) and the huon pine (*daucrydium franklinii*) also yield valuable timber, which, together with the hardwoods from the eucalypti, is largely exported to the neighboring colonies. A species of beech (*fagus cunninghamii*), locally known as the myrtle, and growing in great abundance in some parts of the island, also produces a highly valuable timber, which has not yet received the attention which it merits. There are many beautiful shrubs and plants, but the flowers are usually small and inconspicuous. All the common fruit-trees and culinary vegetables of England have been introduced, and grow with great luxuriance and vigor. Oranges and lemons are cultivated in some situations, but do not usually ripen their fruit. The introduction and cultivation of exotic trees and plants is energetically carried on in the botanical gardens under the direction of the Royal society.

Zoology.—Of the 40 species of mammals, one-half belong to the sub-class *aplousentaria*, comprising the *marsupialia* (kangaroo, wallaby, opossum, wombat, etc.), and two species of the singular order *monotremata* (ornithorhynchus and echidna). Among the marsupial animals peculiar to Tasmania, the chief are the thylacine (*thylacynus cynocephalus*) and the Tasmanian devil (*dasgurnus ursinus*), both of which are sometimes very destructive to sheep in the outlying districts. The skin of the kangaroo is much prized for leather, and there is always a market for opossum fur. Whales and seals, formerly very abundant on the coasts, are now rare; but whaling is still extensively carried on in the adjacent seas. The birds of Tasmania have been admirably described by Gould. The majority are identical with Australian species. The emu is extinct, and black swans are seldom seen in the settled districts. There is abundance of native game, which is now protected by act of parliament during the breeding season. A species of puffin (*Puffinus brevicaudus*), locally known as the mutton-bird, frequents some of the islands in Bass's strait in countless numbers, and many thousands are annually slaughtered for the sake of their oil, and for food by the half-caste islanders. Fish are plentiful in the seas and rivers, the best being known by the local name of trumpeter, and reaching a weight of 40 lbs. There are 13 species of snakes, most of which are venomous, but accidents from their bite are of very rare occurrence. Many species of insects and crustaceans have been described by Erichson, Gray, Gunther, and others. A comprehensive and accurate account of the fauna of Tasmania is still however, a desideratum.

Fallow-deer, and several of the English game-birds, have long been naturalized, and salmon have been introduced after several unsuccessful attempts.

Climate, Soil, Produce, &c.—The climate of Tasmania is fine and salubrious. From observations taken at Hobart Town, and extending over a period of twenty years, the extreme of heat appears to be 105°, and of cold 29° 8'. The mean temperature of the hottest month (January) is 63° 57', and of the coldest (July), 45° 82', and of the whole year, 51° 92'. In some parts of the island, the temperature, even in winter, rarely sinks to 45°. Snow seldom falls in the settled districts, and does not lie on the ground except on the high table-lands of the interior. The average annual rain-fall at Hobart Town is 21.52 in., and the average for the rest of the island about 35 in., except in the western country and the high lands, where a fall of 75 in. has been registered in the year.

The agricultural lands may be divided into three classes—alluvial deposits, tertiary clays, and loamy soils, derived from the decomposition of different kinds of basalt. In their virgin state, some are marvelously productive. On new land, 100 bushels of oats, 70 bushels of wheat, and 15 tons of potatoes per acre, are not uncommon crops. The fertility of the soil has encouraged a system of slovenly farming. In many instances, the land has been cropped with wheat and oats for upward of thirty years without any application of manure, or any rest save an occasional summer fallow. The export trade in the staple articles of produce has much fallen off of late years, partly because the neighboring colonies have begun to depend more upon their own resources, but partly also through the deterioration of the soil from improvident management, and the necessarily increased cost of production. There are skilled and careful farmers in every district, but they are exceptions to the rule. The open pastoral lands are admirably adapted for sheep. The wool from some of the larger establishments is much valued, and brings the highest price in the London market. The cattle and agricultural horses of some of the northern districts are unsurpassed in the colonies. Pastoral and agricultural associations have been formed to promote improvements in the system of farming, and to encourage the breeding and importation of pure stock. The extent of alienated land is over 4,000,000 acres, of which about 340,000 acres are under cultivation. In 1875 the number of horses in the colony was 23,208; of cattle, 110,450; and of sheep, 1,714,168. In 1876 the exports amounted to £1,130,988, the chief staple article being wool; the imports were £1,133,003. In 1876-77 the yield of wheat was 752,070 bush.; barley, 147,536 bush.; oats, 571,485 bush.; potatoes, 27,289 tons; hay, 35,907 tons; hops, 839,514 lbs.

Administration.—Since the passing of the "constitutional act" in 1854, the governing authority has been vested in a parliament, consisting of the governor as the queen's representative, and two elective houses, the legislative council of 16, and the assembly of 32 members. The qualification of voters is, for the former, a freehold of the annual value of £30, or a leasehold of £200; and for the latter a freehold of the value of £50, or the payment of £7 house rental. Graduates of British universities, and all holding a commission in the army or navy, or in holy orders, are entitled, *ex officio*, to vote at the election of members of both houses. The revenue for the year 1877 was £361,771, of which there was derived from the customs the sum of £201,966. The expenditure for the same period was £352,564; and the public debt, £1,589,705. The upset price of land is £1 per acre, payable by installments extending over eight years; but lots which remain unsold after being offered for sale by public auction, may be purchased, under certain restrictions, at greatly reduced rates. In the unsettled districts, large tracts of land are obtainable at nominal prices. In 1862 an act, known as "Torrens's real property act," was passed to facilitate the transfer and conveyance of land. Property which had been brought under the operation of this act can be conveyed, without reference to value, upon payment of 10s. registration-fee, £1 for new certificate of title, and 2s. for forms. Mortgages can be effected on equally moderate terms. At the end of 1874, the land rented from government amounted to 1,308,400 acres, producing a rental of £5,898.

Religion and Education.—By the constitutional act, £15,000 is annually reserved for the support of religion, and is at present divided among the various religious denominations according to their respective numbers at the census. By a return in 1870, there were: Church of England, 53,047; Roman Catholics, 22,091; Presbyterians, 9,064; Wesleyans, 7,187; Independents, 3,931; Baptists, 931; Jews, 232. The state grants are largely supplemented by endowments and by local contributions. For the support of elementary education, £12,000 a year is appropriated by parliament, the disbursement of which is intrusted to a central board, holding its sittings in Hobart Town. The system is based upon the principles established by the Irish national board. The teachers are appointed by the board, and are under the supervision of the inspector of schools. In 1854, the total number of schools was 50, at which the average attendance of pupils was 2,624. In the beginning of 1877 there were upward of 165 schools supported by the government, 297 teachers, 12,557 children on the rolls, with an average daily attendance of 5,973. Of the entire population about 60 per cent can both read and write; about 25 to 30 per cent are unable to read.

For the promotion of higher education, provision is also made by the legislature. Two scholarships, each of the value of £200 a year, and tenable for four years at either of the English universities, are annually open to competition under the direction of the

council of education, and exhibitions to the higher schools, with other local honors, are periodically awarded by the same body.

Aborigines.—The number of the aborigines at the first colonization of Tasmania has been variously estimated, but probably at no time exceeded 3,000. There were several tribes occupying distinct parts of the island, and differing from each other in dialect and customs; but of a generally uniform type more nearly allied to the Negritos of New Guinea than to the aborigines of Australia. The average height of the men was from 4½ to 5½ ft.; of the women, considerably less. Color, a bluish black; the facial angle 75° to 80°; eyes, dark brown, with jet-black pupils; hair, sometimes lank, but generally crisp or woolly; forehead, high and narrow; limbs, lean and muscular; feet, flat and turned inward. Polygamy appears to have been tolerated: the women performed all menial duties, and were specially charged with that of carrying fire from place to place, when the temporary encampment was broken up. Their usual shelter was a "break-wind," constructed of boughs, but traces of rude huts have been observed. In summer, they went entirely naked, at other times wearing coverings made from the skins of the kangaroo and opossum, which formed their chief food. The coast tribes, at certain times of the year, lived almost exclusively on shell-fish, and the remains of their feasts have often been mistaken for recent marine deposits. Among other articles of food were the roots of the esculent fern, the heart of the tree-fern, and grass-tree (*Xanthorrhoea*), the seeds of the boobialla (*Acacia sophora*), and a singular fungus (*mytilis Australis*), commonly known as "native bread," which grows under ground near the roots of decayed trees. No traces of cannibalism were observed. Their only weapons were the spear and waddy, a wooden club about 2 ft. 4 in. in length. The early relations between the settlers and aborigines were friendly; but as the latter were gradually dispossessed of their favorite hunting grounds, they became inveterately hostile. Shot down without mercy by the settlers, they revenged themselves by bloody reprisals, and for many years the unequal struggle continued, until their numbers were reduced to a few hundreds. In 1830, an attempt was made to drive the whole body into Tasman's peninsula, by means of a cordon extending across the whole island, and gradually closing in toward the s.e.; but it failed ridiculously, as might have been foreseen. In the following year, Robinson, a builder of Hobart Town, undertook to conciliate the surviving remnants of the various tribes, with a view to their removal to Flinders island, and this he successfully accomplished, after four or five years of patient, self-denying labor. In spite of all the care bestowed upon these unfortunate people their numbers rapidly decreased, and only 45 remained when the settlement was removed, in 1847, to a more convenient station at Oyster cove, near Hobart Town. There were in 1865 only six remaining. No children had been born among them for many years, and the race is now wholly extinct, the last of the number having died a few years ago.

History.—The island was first discovered by Tasman on Dec. 1, 1642, and named by him Van Diemen's Land, in honor of his patron, the then governor of the Dutch possessions in the East Indies. During the next century, no visit is recorded; but between 1772 and 1802, partial surveys and explorations were made by English and French navigators. In 1803, lieut. Bowen was dispatched from Sydney with a few soldiers and convicts to form a settlement in the s. of Tasmania, which was finally fixed on the spot where Hobart Town now stands. In 1804, a settlement was formed near the mouth of the Tamar, which was removed in 1806 to the spot now occupied by the town of Launceston. From 1817, commenced a rapid increase in the number of free settlers, who received grants of land in proportion to the capital which they brought into the colony, and were subsequently further aided in the clearing and cultivation of their estates by the assignment of convicts as their servants. In 1825, Tasmania was declared independent of New South Wales.

The colony was for a good many years agitated by the question of the disposal and management of the convicts, who were now becoming a prominent and formidable element in the community. At last, in 1853, transportation to Tasmania and New South Wales was finally abandoned by the home government. The abolition of transportation, and the consequent cessation of a vast imperial expenditure, naturally produced a considerable depression in all branches of trade, especially in the southern districts. It is not surprising that the great body of the colonists, instead of setting themselves manfully to turn the true and natural resources of the country to the best account, have rather looked for some great discovery of rich gold-fields, or some gigantic works undertaken under the auspices of government, as the only means by which the prosperity of the colony was to be assured. But such a state of things must ultimately work its own cure. Viewed in a true light, the progress, social, material, and political, has presented a more hopeful aspect since the extinction of the convict system than at any earlier period. For years after the discovery of gold in Australia, the *expatriates* of Tasmania flocked in crowds to the neighboring colonies, attracted by the prospect of richer gains, and glad to escape from police surveillance in a country where their antecedents were too well known. Those who remained had, for the most part, by this time become orderly, well-conducted members of the community, not to be distinguished from the immigrant population by whom they were surrounded. Necessity will in due time develop the enterprise and energy which have too long lain dormant. Some of the older settlements may prove inadequate to the maintenance of their former

population, but the rich lands of the n. coast offer to industrious settlers a field which is practically inexhaustible.

TASMANIA, a genus of shrubs of the natural order *magnoliaceæ*. *T. aromatica* is an evergreen bush of Van Dieman's land, growing in the richest soils on the margins of rivers and in shady ravines, and sometimes forming thickets of large extent. Every part of the plant is highly aromatic and pungent. The fruit is occasionally used as pepper. This shrub requires protection from frost in England.

TASSAERT, NICOLAS FRANÇOIS OCTAVE, 1800-74; b. France; studied art at the Paris school of art and under eminent masters of painting. His first picture was exhibited in 1831. His field was wide, including historical and *genre* pieces as well as portrait-painting. Among his best productions are "Le Marchand d'Esclaves;" "Le Sommeil de l'Enfant Jésus;" and "Funérailles de Dagobert à Saint Denis."

TASSIN, A. G., b. France, 1843; educated at the St. Cyr military school of France; was appointed 1st lieut. 35th Ind. vols., 1861; capt., 1863; maj., 1864; col., 1865; breveted brig.gen. and maj.gen. for gallantry. He resigned to accept commission in the French army during the Franco-Prussian war; was made knight of the legion of honor. He was afterward reappointed by pres. Grant, and is col. in the U. S. army. He is author of *Northern California Indians*; *The Indian Tribes of the Pacific Coast*; *The Flora of Arizona*; and translations of military works.

TASSISUDON, the capital of Bhotan (q.v.), stands on the right bank of the Godadda, an affluent of the Brahmaputra, in lat. 27° 30' north. Many of the inhabitants, the number of whom has not been ascertained, are employed in manufacturing paper, and in making brass images and ornaments for their places of worship.

TASSO, BERNARDO, an Italian poet of considerable distinction, but most famous as the father of the illustrious Torquato, was b. at Bergamo, Nov. 11, 1493. Both by his father's and mother's side he was connected with the ancient family of the Tassi, known in the 13th c. for having organized and superintended the postal service in Italy, Spain, and Germany. His uncle, Luigi Alessandro, bishop of Recanati, took charge of his education, and under his care he turned out a fine classical scholar, his love of poetry at the same time becoming every year more ardent. The assassination of the cardinal in 1520, deprived him at once of protection and support, and for several years he wandered about Italy in a rather necessitous condition. Like his son, he was exceedingly fond of the patronage of noble lords and the smiles of noble ladies. After 1525 we find him high in favor with persons of influence. Guido Rangone, gen. of the pontifical forces, intrusted him with several missions, among others to the prince of Salerno, who appointed him his secretary; and Tasso accompanied the prince on the expedition against Tunis in 1534. In 1539 he married, at Salerno, a young lady of Sorrento, Porzia de' Rossi, who added genuine merit to the advantages of birth, beauty, and fortune, and by whom he became the father of Torquato. The fall of the prince of Salerno (who had incurred the enmity of Charles V.) brought with it the ruin of Tasso's worldly prosperity, and he was obliged to seek for a new patron. He was not long in finding friends. Guidubaldo, duke of Urbino, and Guglielmo, duke of Mantua, strove for the honor of attaching the poet to their court. The latter succeeded, and named him governor of the city of Ostiglia, where he died Sept. 4, 1569.

Tasso's principal writings, chronologically arranged, are: *Rime* (Ven. 1531); *I tre Libri degli Amori* (Ven. 1537); *Ode e Saluti* (Ven. 1560); *L'Amadigi*, *Poema* (Ven. 1560); and *Il Floridante*, *Poema* (Mant. 1587). Of these the principal is *L'Amadigi* (Amadis), which some Italian critics have not hesitated to place above the poem of Ariosto; but without adopting this extravagant estimate, we may justly admire it for the sweetness and elegance of its language, and for the beauty of its descriptions and comparisons.—For a good idea of the politics and literature of the time, see Seghezzi's edition of his *Lettere* (3 vols., Padua, 1733-51), to which there is prefixed a biographical notice.

TASSO, TORQUATO, one of the greatest poets of Italy, was the son of the preceding, and was born at Sorrento in Naples, Mar. 11, 1544. His earliest education was received from the Jesuits. During his childhood, Tasso's father was an exile, but the affectionate solicitude of his mother well supplied the want of paternal care. In 1554 he went to Rome to join his father, and left his mother (whom he was destined never again to see) in a convent at Naples. At Rome, and subsequently at Bergamo, Urbino, Pesaro, and Venice, he continued to prosecute his studies. He assisted his father in copying, correcting, and even in completing his poem *L'Amadigi*, though as yet only 16 years of age. No wonder old Bernardo was delighted at the promise shown by his son, and prophesied in his letters that Torquato would yet become a great man. Later, however, sad experience of the miseries of a poet's life induced him to send Tasso to Padua, to study jurisprudence under the celebrated Paneiroli. But whom the gods have made poetical can never sink into a lawyer. The youth remained at Padua a year, and wrote *Rinaldo* (Venice, 1562), a poem in 12 cantos, the hero of which is the son of Aymon, and cousin of Roland. It belongs, therefore, to the class of heroic romances. After the first burst of anger was over, Bernardo forgave his son for following his example rather than his precept, and became prouder of Tasso's genius than ever. Tasso now betook himself to the university of Bologna, to study philosophy, and is said to have distinguished himself

by an extraordinary facility in the discussion of the most elevated and abstract themes—a circumstance that perhaps says more for his power of rhetoric than his power of speculation. On leaving Bologna, he spent some time with friends at Castelvetro, Modena, and Correggio, but returned to Padua at the request of his friend Scipio de Gonzaga, afterward cardinal, who had established a literary academy there, of which Tasso became a member. It was during this second residence at Padua that he conceived the first idea of his great work, the *Gerusalemme Liberata*, a heroic record of the conquest of Jerusalem by the crusaders under the command of Godfrey de Bouillon. Lamartine beautifully describes the mingled motives of the poet: "Urged by piety no less than by the muse, Tasso dreamed of a crusade of poetic genius, aspiring to equal by the glory and the sanctity of his songs, the crusaders of the lance he was about to celebrate." The same critic goes on to observe, in allusion to the less noble passion for the applause of courts that marked the poet: "The names of all the noble and sovereign families of the west would be revived in this epic catalogue of their exploits, and would attract to the author the recognition and favor of the great. . . . Finally, the poet was himself a knight, noble blood flowed in his veins, to celebrate warlike deeds seemed, as it were, to be associating his name with those of the heroes who had performed them on the field of battle: thus religion, chivalry, poetry, the glory of heaven and earth, the hope of eternal fame, all combined to urge him to the undertaking." Bernardo heard of his son's design with exulting joy, and blessed heaven for making Torquato a greater genius than himself. Meanwhile (1565), Tasso had been introduced by cardinal Luigi d'Este to whom he had dedicated the *Rinaldo* to his brother, Alfonso II., sovereign duke of Ferrara. Here for a time he was supremely happy. Young, handsome, courteous, and with that proper tinge of melancholy in his disposition that possesses an irresistible charm for women, he soon became a universal favorite with the beauties of the court. While their bright eyes rained influence, Tasso painted his *Armida* and *Herminia* almost without effort. It is only just to add that the attempt to seek the origin of his subsequent miseries and madness in a presumptuous passion for Leonora, sister of the duke of Este, which was first encouraged, then repulsed, and finally punished with imprisonment, is utterly at variance with the notorious facts of the case. Space does not permit us to examine the question here, but it appears necessary to correct errors of traditions so specious as to have imposed upon illustrious men. Tasso courted, platonically and otherwise, various ladies of the court—a pretty chambermaid even was not beneath his notice; but there is not a vestige of evidence to show that he lifted his eyes to the sister of his sovereign, or that such a suspicion was ever harbored by the lady herself or her brother. In truth, his madness was connected in its origin more closely with his poetry than with his loves. Having finished his great epic about 1575, he sent a copy of it to a society of scholars, critics, and churchmen at Rome, to get their opinion of it. It would have been far better had he published the poem at once, without placing it at the mercy of critics who were delighted to have the opportunity of finding fault before the public was in a position to praise. The critics would then have been forced to swell the chorus of general admiration. Tasso was tortured by their waspish comments, and, with pitiable agonies, proceeded to make his work more agreeable to his incapable judges. Gradually a morbid melancholy overpowered his reason; the spites and jealousies that are never absent from a gay and pleasure-loving court contributed to increase his mental disorder. He believed that invisible persecutors had denounced him to the inquisition as a heretic. It was in vain that Alfonso and his sisters tried to calm the perturbations of his spirit, and even got the inquisition to write him a reassuring epistle. His paroxysms increased in violence. Finally one evening (June 17, 1577), he drew his dagger in the apartments of the duchess of Urbino, to stab a domestic whom he conceived to be one of his secret enemies; whereupon Alfonso had him conveyed to a prison-hospital for the benefit of his health, rather than to punish him. On July 20 he made his escape, and fled across the Abruzzi to his birthplace, Sorrento, where he took refuge with his sister. The air of his native place quickly restored him to health; but no sooner had he recovered than he began to yearn for the old excitements, begged Alfonso to take him back, and when that prince drily informed him that he might return if he pleased, Tasso greedily availed himself of the cold permission, and was soon as wretched as before. A new flight ensued, this time toward the north of Italy. The unhappy poet wandered at last half-naked into the city of Turin, where he was humanely received by the marquis d'Este, brother of Alfonso. After some time, he again ventured to return to Ferrara, Feb. 21, 1579, but only to madden, almost as soon as he breathed its noxious air. Alfonso was again obliged to put him under constraint, in which he remained upward of seven years, when the duke, at the request of several of his brother sovereigns, released him (July 5, 1586). During the remainder of his life Tasso lived chiefly at Naples. Almost the last incident of his career was his visit to Rome to receive (like Petrarch) the honor of a public coronation on the Capitol. The excitement was too much for his ruined frame. A slow fever seized him; he was removed to the convent of Santo Onotrio, on the Janiculum, and there died, April 25, 1595, after a brief illness. See Manso, *Vita di T. Tasso* (Nap. 1619); Jacobi, *Vindicie T. Tasse* (Gott. 1763); Serassi, *Vita del Tasso* (Rome, 1785); Black, *Life of T. Tasso* (Edinb. 1810); Ebert, *T. Tasso's Leben* (Leip. 1819); Zuccala, *Della Vita di Tasso* (Mil. 1819); Milman, *Life of T. Tasso* (Lond. 1850); Cibrario, *Degli Amori e Della Prigione di Tasso* (Tur. 1862).

Besides his *Gerusalemme Liberata*, Tasso wrote a great number of works in verse and prose, among which may be mentioned *Rime, insieme con altri Componimenti* (Ven. 1581); *Dialoghi e Discorsi* (Ven. 1586-87); *Lettere Familiari* (Bergamo, 1588); *Rime* (Brescia, 1592-93); and *Gerusalemme Conquistata* (Rome, 1593). The most complete edition of his works appeared at Pisa (1821-32), in 33 vols.

TASTE, ORGAN AND SENSE OF. The principal seat of the sense of taste is the mucous membrane of the tongue, in which dissection reveals a *cutis* or *chorion*, a *papillary structure*, and an *epithelium*. Of the *cutis*, it is sufficient to remark that it is tough, but thinner and less dense than in most parts of the cutaneous surface, and that it receives the insertions of the intrinsic muscles of the tongue, which will be described when we treat of that organ generally. The *papillary structure* differs from that of the skin in not being concealed under the epithelium, but in projecting from the surface like the villi of the digestive canal, and it thus gives to the tongue its well-known roughness. The *epithelium* (q.v.) is of the scaly variety, as on the skin, but is much thinner on the tongue than on the skin. It is most dense about the middle of the upper surface of the tongue, and it is here that, in disordered digestion, there is the chief accumulation of *fur*, which in reality is simply a depraved and over-abundant formation of epithelium. The *papilla* on the surface of the tongue are either *simple* or *compound*. The former, which closely resemble those of the skin, are scattered over the whole surface of the tongue in parts where the others do not exist, and they likewise participate in the formation of the compound papillae, which, from their forms, are respectively termed (1) the *circumvallate* or *calyciform*, (2) the *fungiform*, and (3) the *conical* or *filiform*.

The *circumvallate papillae* are not more than eight or ten in number, and are situated in the form of a V at the base of the tongue. Their function seems to be to secrete mucus, as well as to take part in the act of tasting. They consist of "a central flattened projection of the mucous membrane of a circular figure, and from $\frac{1}{10}$ to $\frac{1}{12}$ of an inch wide, surrounded by a tumid ring of about the same elevation."—Todd and Bowman, *Physiological Anatomy and Physiology of Man*, 2d ed. vol. i. p. 437. The *fungiform papillae* are scattered over the surface in front of the circumvallate papillae, and about the sides and apex. They are usually narrower at the base than at the apex, where they are about $\frac{1}{10}$ of an inch in diameter. They are covered with simple or secondary papillae, and their investing epithelium is so thin that the blood circulating in them gives them a red color, which is not seen in the conical papillae, among which they are distributed. They contain nerves terminating in loops. The shape of the *conical* or *filiform papillae* is indicated by their names; and even if they take little part in the sense of taste directly, it is convenient to describe them here. Their average length is about $\frac{1}{10}$ of an inch. The papillae terminate in long pointed processes, which are bathed by the mucus of the mouth, and are capable of moving in any direction, although they are generally inclined backward. Some of the stiffer of these epithelial processes inclose minute hairs. Messrs. Todd and Bowman surmise, on structural grounds, that the filiform papillae "can scarcely share in the reception of impressions which depend on the contact of the sapid material with the papillary tissue. The comparative thickness of their protective covering, the stiffness and brush-like arrangement of their filamentary productions, their greater development in that portion of the dorsum of the tongue which is chiefly employed in the movements of mastication, all evince the subservience of these papillae to the latter function rather than to that of taste; and it is evident that their isolation and partial mobility on one another must render the delicate touch with which they are endowed more available in directing the muscular actions of the organs. The almost manual dexterity of the tongue in dealing with minute particles of food is probably provided for, as far as sensibility conduces to it, in the structure and arrangement of these papillae."—*Phys. Anat. and Phys. of Man*, vol. i. p. 441. Notwithstanding the difference in their outward form and mode of arrangement, the simple papillae, which have been detected by Todd and Bowman as scattered over the whole dorsum of the tongue (although concealed under the common sheet of epithelium), and those clothing the circumvallate and fungiform papillae, do not seem to present any structural difference; and their epithelium, which is very thin, readily permits the transudation of sapid substances dissolved in the mucus of the mouth. With regard to the use of the singular configuration of the circumvallate and fungiform papillae, "it may be conjectured that the fissures and recesses about their bases are designed to arrest on their passage small portions of the fluids in which the sapid materials are dissolved, and thus to deraim them in contact with the most sensitive parts of the gustatory membrane."—*Op. cit.* p. 441.

There has been much discussion regarding the precise seat of the sense of taste and the true nerves of taste. Although the surface of the tongue is the special seat of gustative sensibility in man, the sense of taste is by no means restricted to that organ, being diffused, in a less degree, over the soft palate, the arches of the palate, and the fauces. Moreover, the gustative sensibility varies on different parts of the surface of the tongue. It is generally allowed that acute taste "resides at the base of the tongue, over a region of which the circumvallate papillae may be taken as the center, and also on the sides near the base. These parts are supplied solely by the glossal twigs of the glosso-pharyngeal nerves. Some writers, among whom are Valentine and Wagner, believe the mid

dle and anterior parts of the dorsum of the tongue to be usually incapable of appreciating flavor; while numerous others hold the contrary opinion, with which our own careful and repeated experiments, on other persons as well as ourselves, quite accord. Sour, sweet, and bitter substances applied to the sides, and especially to the tip of the protruded tongue, we find to be at once distinguished; though, when placed on the middle of the dorsal region, they make little or no impression till pressed against the roof of the mouth. This region of the tongue is supplied almost solely by the lingual branch of the fifth nerve. We conclude generally, with regard to the tongue, that the whole dorsal surface possesses taste, but especially the circumferential parts, viz., the base, sides, and apex."—*Op. cit.*, pp. 442, 443. The investigations of Messrs. Todd and Bowman further show that the soft palate and its arches are endowed with taste in some persons, but not universally, while they got no evidence in any case of gustative sensibility on the pharynx, gums, or elsewhere. The soft palate and its arches are supplied by palatine branches from Meckel's ganglion, and sparingly by the glosso-pharyngeal nerves. From (1) the evidence afforded by the anatomical distribution of the nerves to parts enjoying the sense of taste, (2) the evidence of experiments, in which the various nerves of the tongue were divided, and (3) the evidence afforded by disease, it may be safely inferred that the glosso-pharyngeal and the lingual branches of the fifth pair of nerves respectively participate in the sense of taste; and there is also reason to attribute a share to the palatine branches of the fifth.

Impressions of taste may be produced by a mechanical or chemical excitement of the gustatory nerves. A quick light tap of the finger on the tip of the tongue causes a taste, sometimes acid, sometimes saline, which lasts for several seconds; and galvanism acts similarly. If the surface of the tongue, near the root, be touched with a clean dry glass rod, or a drop of distilled water be placed upon it, a slightly butterish sensation is produced; and if the pressure be continued, a feeling of nausea ensues. If a small current of cold air be directed against the tongue, it excites a cool saline taste like that of salt-peter. From the experiments of E. H. Weber, it appears that one of the conditions requisite for the due exercise of the sense of taste is a temperature not departing far on either side from the natural standard. Thus, if the tongue be immersed for a minute in water at a temperature of 125°, or in iced water, the taste of sugar, etc., is no longer perceived. In order that sapid bodies should cause taste, it is necessary that they should be dissolved, and made to permeate the tissue of the papillæ, so as to come in contact with their nerves. This is proved by the two following facts: 1, that every substance, whether solid, fluid, or gaseous, which possesses a distinct taste, is more or less soluble in the fluids of the mouth, while substances which are perfectly insoluble are only recognized by the sense of touch; and 2, that if the most sapid substance be applied in a dry state to a dried part of the surface of the tongue, no sensation of taste is excited. Bitters and acids appear to be the most sapid bodies, since they may be diluted to a greater extent than any other known substances without ceasing to excite sensations of taste. Thus, according to Valentin, 1 part of extract of aloes, or of sulphuric acid, in 900,000 of water, and even 1 part of sulphate of quinia in 1,000,000 parts of water, may, with ease, be distinguished from perfectly pure water. "The contact of a sapid substance," says Dr. Carpenter, "much more readily excites a gustative sensation when it is made to press upon the papillæ, or is moved over them. Thus there are some substances whose taste is not perceived when they are simply applied to the central part of the dorsum of the tongue, but of whose presence we are at once cognizant by pressing the tongue against the roof of the mouth. The full flavor of a sapid substance, again, is more readily perceived when it is rubbed on any part of the tongue, than when it is simply brought in contact with it, or pressed against it. Even when liquids are received into the mouth, their taste is most completely discriminated by causing them to move over the gustative surface: thus, the "wine-taster" takes a small quantity of the liquor in his mouth, carries it rapidly over every part of its lining membrane, and then ejects it."—*Principles of Human Physiology*, 6th ed. p. 621. Most sapid substances affect the nerves of smell to a greater or less degree, as they pass down the throat; and it is this compound of taste and smell that constitutes *flavor*. It is a common habit to hold a child's nose when he is taking a nauseous draught, with the view, as is supposed, of deadening the taste. The efficacy of the process depends upon the exclusion of smell, and the reduction of the flavor of the medicine to its mere taste. The agreeable sensation produced by sipping good wine is due to what is termed its *bouquet*, or in other words, to its flavor, or combined taste and smell. Some substances leave a taste in the mouth very different from that which they first produced. This *after-taste* is usually bitter; but in the case of one of the most bitter substances known, namely, tannin, it is sweet. This connection seems, in a degree, to correspond to the complementary colors in vision.

There can be no doubt that the sense of taste has for its primary object to direct us in the choice of food, to make the act of eating agreeable, and to excite the flow of mucus and saliva which aid the digestive process; and among the lower animals, the instinctive perceptions connected with this taste are much more remarkable than in man. As a general rule, it is found that those substances whose taste is agreeable are useful articles of food, and *vice versa*; although there are some well-known exceptional cases.

Sir Henry Holland, in his *Medical Notes and Reflections*, observes that in the majority of instances of actual illness, the desires of the patient as to food and drink may be safely complied with, even when some seeming extravagance of diet is suggested; and that in the early stage of recovery from gastric fevers, he has seen many curious instances of such contrariety to all rule acquiesced in with manifest good to the patient. "Dietetics," he adds, "must become a much more exact branch of knowledge, before we can be justified in opposing its maxims to the natural and repeated suggestions of the stomach, in the state either of health or disease."

TATE, a co. in n.w. Mississippi; watered by Coldwater river, traversed by the Chicago, St. Louis and New Orleans railroads; about 400 sq.m.; pop. '80, 18,721—9,632 colored. The surface is mostly level. The soil is fertile. The principal productions are corn, wheat, cotton, and potatoes. Co. seat, Senatobia.

TATE, NAHUM, a poet and dramatist, son of the rev. Dr. Faithful Tate, was b. in Dublin in 1652, and educated at Trinity college, Dublin. In 1690, he succeeded Shadwell as poet-laureate, and held that dignity till his death in 1715. His habits were somewhat improvident, and in the latter part of his life resided within the precincts of the mint at Southwark, then a privileged sanctuary for debtors—hence perhaps that "down-cast look" and inability to "say much for himself," for which, it is said, he was remarkable. His writings include nine or ten dramatic pieces, *Panacea*, or a *Poem on Tea*, various birthday odes, and an elegy on the death of queen Mary. He lived to write the first birthday ode for George I. But Tate is best known by the metrical version of the Psalms, which he executed in conjunction with Dr. Nicholas Brady, chaplain to king William and queen Mary, which was attached to the prayer-book, and came into general use in the church of England, supplanting the older version made in the reign of Edward VI. by Sternhold and Hopkins.

TATHAM, WILLIAM, 1752-1819; b. England; emigrated to America in 1769 and engaged in business in Virginia. He served in the revolutionary war, was admitted to the bar in 1784, and two years later settled in Lambarton, N. C., which he represented in the legislature in 1787. He was superintendent of the London docks, 1801-5, when he returned to this country. In 1817 he became a United States military storekeeper. Having lost his property he committed suicide on Washington's birthday by throwing himself before a cannon.

TATIAN, one of the early apologists of Christianity against the pagan philosophers, and the founder of a sect which, whether under his own name, or under various other appellations derived from its peculiar tenets or practices, attracted considerable notice in the primitive ages. Tatian was b. in Syria or Assyria about the year 130. Having cultivated rhetoric and philosophy in various places, he came to Rome about 162, where he became the disciple and friend of Justin the martyr, and was by him converted to Christianity. He is known to have written many works—*infinite volumina*, says Jerome—of which, however, only one is preserved, the Apology already referred to. The date of its composition is uncertain, but it seems probable that it was written before the death of Justin (166 A.D.). No trace appears in the Apology of the heterodox opinions of Tatian, and it is alleged by Tertullian (*Adv. Her.* i. 28, 1) that it was not till after the death of Justin that he fell into the errors to which he has given a name. He then removed to the East, and is said to have established himself in Mesopotamia. Without entering into the details of Tatian's peculiar opinions, it will be enough to say that, especially in their moral aspect, they formed the foundation of one of the great divisions of Gnosticism (q.v.). Starting from the common principle of dualism, and of the origin of matter from the evil principle, and its consequent evil nature, Tatian, unlike the Egyptian Gnostics, held the necessity of overcoming the corrupt nature of man, and purifying it by abstinence and ascetic rigor. Accordingly, he reprobated marriage, and condemned all sensual indulgence. One of his "opinions," affirming the damnation of Adam, was peculiarly odious to the orthodox party. He condemned the use of wine so strongly as to forbid it even in the celebration of the Eucharist, in which his followers permitted only water to be used, whence they received the name of *Hydroparastatai* (from *hydor*, water, and *paristemi*, I present), and in Latin *Aquarii*. From their generally rigorous asceticism, they were called *Encratites* (from *engkratein*, to keep continent). In their dogmatic views as to Docetism, the Demiurge, and Emanations, they differed little from other Gnostics of the Syrian school. See GNOSTICS, MANICHEANS, MYSTICISM.

TATIUS, ACHILLES, one of the later Alexandrine authors, of whose life absolutely nothing is known. He was formerly thought to have flourished during the 2d or 3d c. A.D.; but as he undoubtedly imitated the style of Heliodorus of Emesa, he cannot be placed earlier than the beginning of the 6th c. (see NOVELS). Suidas, who calls him Achilles Statius, says that he was originally a pagan, but that he was afterward converted to Christianity, and rose to be a bishop. If this be true, the romance which has preserved the author's name, *To Kata Leukippen kai Kleitophon'a* (The Loves of Leucippe and Cleitophon), must have been composed before his conversion, for it is in parts too licentious and too heathenish to be the work of a Christian, and more espe-

cially of a convert. The first edition of the Greek original appeared at Heidelberg in 1601; another with a copious commentary, was published by Salmasius in 1640; but the best is that by Fr. Jakobs (Leip. 2 vols., 1821).

TATNALL, a co. in s.e. Georgia; drained by the Great Ohoopce, the Cannouchee, and the Altamaha rivers, the last two being its n.e. and s. limits; about 1200 sq.m; pop. '80, 6,985—6,969 of American birth; 1974 colored. The surface is level; the soil sandy and unproductive; cotton, corn, sweet potatoes, and rice are the staples. Co. seat, Reedsville.

TATNALL, JOSIAH, 1762-1803; b. Georgia; joined the army of gen. Wayne, 1780; appointed col., 1793; brig.gen., 1800; was prominent in military affairs; often a member of the legislature; U. S. senator, 1796-99; governor of the state, 1801-2.

TATTA (more correctly, **THATTA**), a t. of Sind, on the right bank of the Indus, and at the head of the delta of that river, 64 m. e. of Kurachi. In former times, Tatta was a most flourishing town, and manufactured fabrics of silk and cotton—a branch of industry that has almost wholly disappeared. The only noticeable structure is the mosque of Shah-Jehan, built of brick, which is now falling into decay; but the vast cemetery of Tatta deserves mention. It has an area of 6 sq.m., contains, it is calculated, at least a million tombs, and has room for not less than four millions. Pop. of Tatta, about 10,000.

TATTAM, HENRY, D.D., LL.D., 1788-1868; b. Ireland; educated at Trinity college, Dublin, and at Göttingen and Leyden; ordained in the church of England; rector of St. Cuthbert's, Bedford, 1818-45; archdeacon of Bedford, 1845; rector of Stamford Rivers, Essex, 1849. He traveled in the east, and became distinguished as an orientalist, in which department he published various works. Among the ancient Syriac MSS. which he found at a convent in Egypt were the *Ecclesiastical History* of John bishop of Ephesus, and *Epistles of Ignatius*.

TATTLER. See **SANDPIPER**, *ante*.

TATT00, in military life, is the beat of drum and bugle-call sounded at sunset to draw in all stragglers and others on detached duty.

TATTOOING, a custom extensively prevalent among savage nations, of marking the skin with figures of various kinds, by means of slight incisions or punctures and a coloring matter. The term is of Polynesian origin, and is said to be derived from a verb *ta*, which signifies to strike. Tattooing is almost universal in the South Sea islands, except where Christianity and civilization have put an end to it. New Zealanders' heads, exhibiting tattooing, are among the curiosities to be seen in museums; and at one time it was very common for the masters of vessels visiting New Zealand to purchase them and bring them home, although there is too much reason to believe that the price paid for them stimulated the feuds of the natives. The tattooing of the New Zealanders and other South Sea Islanders often covers the whole face, and sometimes also the chest, arms, and other parts of the body with elaborate patterns. It is performed in youth, and marks the transition from boyhood to manhood, like the assumption of the *toga virilis* among the ancient Romans. The operation is accompanied with superstitious ceremonies, and is attended with considerable pain, which, of course, is to be endured with manly indifference. An instrument of bone, toothed on the edge, is employed, which is applied to the skin, and struck with a piece of wood, having first been dipped in a thick mixture made by rubbing down charcoal with a little water. The marks which result are permanent, and appear black on a brown skin; although they are dark blue on the skin of a European. Tattooing is, or has been, practiced in almost all parts of the world. It seems to be one of the practices prohibited to the Jews, in Lev. xix. 28, "Ye shall not make any cuttings in your flesh for the dead, *nor print any marks upon you*," from which may be inferred its prevalence among the surrounding tribes in the days of Moses, and its connection with their superstitions. The Bedouin Arabs, the Tunguses, and other eastern tribes, and many tribes of American Indians, practice it at the present day. Among the Bedouins, it is a favorite mode of female adornment. It prevailed among the ancient Thracians, and was distinctive of high rank. The ancient Britons also practiced it, and traces of it appear to have lingered in England till after the Norman conquest. Perhaps the practice of sailors to print anchors and other marks on their arms, may be regarded as a relic of it still subsisting.

TAU, Cross, in heraldry, a cross of a form somewhat resembling the Greek letter *tau*. St. Anthony is generally represented with a cross of this description, embroidered on the left side of his garment.

TAUCHNITZ, KARL CHRISTOPH TRAU, a famous German printer and bookseller, was b. at Grosspardo, near Leipsic, in 1761. Bred a printer, he began, in 1796, a small printing business of his own in Leipsic, with which he shortly after conjoined publishing and type founding, and which, in process of time, became one of the greatest establishments of the kind in Germany. In 1809 he began the issue of a series of editions of the classic authors, the elegance and cheapness of which gave them a European

circulation. By offering a prize of a ducat for every error pointed out he was able to bring out, in 1828, an edition of Homer of extraordinary correctness. He was the first to introduce (1816) stereotyping into Germany; and he also applied it to music, which had not been attempted before. In the latter years of his busy life, he stereotyped the Hebrew Bible, and the Koran in the original Arabic. On his death, in 1836, the business was continued by his son, KARL CHRISTIAN PHIL. TAUCHNITZ.—A nephew of the elder Tauchnitz, CHRISTIAN BERNH. TAUCHNITZ, also set up a publishing establishment in Leipzig, combined with printing. Among the most noted of his undertakings is the well-known issue of "British Authors" (begun 1842), of which upward of 1200 vols. have appeared. Ennobled in 1860, Tauchnitz was made one of the few Saxon life-peers in 1877.

TAULER, JOHN, a remarkable mystic and preacher, was b. at Strasburg in 1290, and died there June 16, 1361. About the year 1308, renouncing a considerable fortune, he entered into the mendicant order of Dominicans, and afterward studied theology in Paris, showing at that early period a predilection for speculative and mystic writings, as the scholastic philosophy and the prevailing theology of the schools did not satisfy him. Notwithstanding this tendency, his predominating practical turn of mind led him, on his return to Strasburg, to preaching and pastoral duty; and this he continued to practice with zeal and undaunted courage, even when, in consequence of the excommunication which the pope had hurled against the emperor Ludwig, the country had fallen into a state of dreadful distraction, and almost all the clergy, in obedience to the interdict issued by the bishop of Strasburg, had suspended worship. Although Tauler was now 50 years old, and had enjoyed celebrity for several years as a preacher, so powerfully was he influenced by a Waldensian of the name of Nicholas von Basel, who paid him a visit in 1340, that he gave himself up for two years to ascetic exercises and devout contemplation. Afterward, however, he betook himself more decidedly to vigorous exertions on behalf of the despised and oppressed people, and preached with wonderful power, inveighing against the avarice, ostentation, and hard-heartedness of the laity as well as of the clergy; and, although not departing from the doctrines of the church, yet fearlessly exposing its abuses, and even not sparing the pope. Thus it happened, that although he had indefatigably administered the consolations of religion in the midst of the horrors and desolation of the black death (q.v.), the bishop interdicted him from preaching, and he was obliged to quit his native town. He repaired to Cologne; but nothing further is known, either of his residence there or of his return to Strasburg, where, after a life full of toil, denial of self, and beneficence to others, he died, an old man of 70 years, and was buried in his cloister. If not the greatest German preacher of the middle ages as a whole, Tauler certainly was the greatest of his times. As his mysticism was in noway passive, but aimed at rising above the sad condition of his times and the failings of the church by inward piety and a love self-dying but at the same time active; so his style, both in his preaching and in his devotional work, was lively, impressive, picturesque, and had altogether a practical direction. Among his devotional works, the *Nachfolge des armen Leb. us Christi* holds the first place. Whether the sacred hymns which bear his name really belong to him, is doubtful. Of his writings and sermons, in which he always used the German language, many have been preserved in MS.; and since 1498, numerous editions have been published, but untrustworthy, and often translated into the dialect of the place where they happened to be printed. A careful translation into new High-German has been published by Schlosser (*Predigten*, 3 vols. Frank. 1826; *Nachfolgung des armen Lebens Christi* (Frank. 1833); Schmidt, *Johannes Tauler von Strasburg* (Hamb. 1841); and Susannah Winkworth, *Life and Times of Tauler*, with 25 of his sermons translated from the German (Lond. and New York, 1857).

TAUNTON, a flourishing city of Bristol co., Mass., on Taunton river, 35 m. s. of Boston, and 30 m. e.n.e. of Providence. The falls of Taunton river and its branches furnish water-power to numerous factories, among which are 6 cotton-mills, 7 for machinery, 2 for locomotives, 6 foundries, 2 tacks and brads, copper and zinc, 2 britannia ware; iron, metallic gas-pipes, enameled cloth, screws, files, arms, crucibles, fire-brick, etc. In copper manufacture, a capital of about £180,000 is invested; in making iron, which is the chief manufacture, about £400,000. Pop. '75, 20,429. Seven railways pass through Taunton, and it has also a considerable coasting-trade, and important fisheries of shad, herrings, and alewives. There are 19 churches, 60 schools, a state hospital for the insane with 400 patients, academy, court-house, 1 daily and three weekly newspapers, 3 banks, etc. Taunton was settled from Taunton in England in 1638. Its first minister was William Hooke, afterward a chaplain of Cromwell.

TAUNTON, *Tone ton*, so named from being built on the banks of the river Tone, is situated in the extensive and beautiful valley of Taunton Dean, or vale of Taunton, in the county of Somerset, 44 m. s.w. of Bristol by railway. It communicates by railway with the Bristol and English channels. The streets are wide, well-paved, and lighted; the shops are modern and capacious, but the woolen and silk factories which were once extensive here have almost wholly departed. Assizes are held here twice yearly. Taunton is the headquarters of the Somerset archeological and natural history society, in connection with which there is an extensive museum, placed in the ruins of the Norman castle—rich especially in fossils from the Devonian strata, and the bones of mam-

malia of the cave period from Mendip and the Somersetshire gravels—and a well conducted reading-room. There is a collegiate school founded by bishop Fox, 1522, two dissenting colleges, several other good schools, and many charitable and other institutions. Taunton, which is a parliamentary borough, returns two members to the house of commons. Pop. '71, 15,466. Ina, king of the West-Saxons, built a castle in Taunton about 700 A.D. This was soon after destroyed, but another fortress was built on the site soon after the conquest, at which period the town had a mint. In 1127, Giffard, bishop of Winchester, built and endowed a priory for the canons of St. Augustine; and in 1322 we find a house of Carmelite friars. The church of St. Mary is a magnificent specimen of perpendicular architecture, and is famous for its graceful and delicately ornamented tower. That of St. James was the conventual church of Taunton priory. The shire hall and the literary institution are handsome modern buildings. To Taunton castle, Perkin Warbeck fled when he failed in storming Exeter. During the civil wars between Charles and the parliament, the town was twice besieged by Goring and twice successfully defended by col. Blake. In Taunton, Monmouth received the heartiest welcome, and judge Jeffreys exercised his unbounded cruelty.

TAUNUS MOUNTAINS. See NASSAU.

TAURIDA, a government of South Russia, bounded on the e. s., and s. w. by the sea of Azov and the Black sea. Area, 24,140 sq. m.; pop. 658,549, mostly Nogai Tartars. The peninsula of the Crimea (q. v.) forms the southern portion of the government, and is connected with the northern portion by the isthmus of Perekop (q. v.). The region n. of the isthmus is flat; the Crimea contains mountain-ranges which rise upward of 5,000 feet. The only great river is the Dnieper, which forms the n. w. boundary; and the other principal streams are the Salgir and Alma in the Crimea. Among the salt lakes of the Crimea, which are very productive in salt, the lake of Sakky is celebrated for the efficacy of its waters in certain cases of disease. The climate is temperate and warm on the southern shores of the Crimea. The soil is fertile, but cultivation is carried on on a very limited scale. In the north the pasturage is very rich, and cattle-breeding is the main employment of the inhabitants. In the south the mountains are clad with forests, the tobacco-plant is successfully cultivated, and fruit-growing and wine-culture are the principal occupations. The Crimean wines, the *bouquet* of which resembles that of Burgundy and the Rhenish wines, are of a very good quality. The native riches of the government, its excellent ports and harbors, promise great commercial progress. Simferopol (q. v.), in the Crimea, is the capital of the government, and Sevastopol (q. v.) and Theodosia are ports of rapidly increasing importance.

TAURINE, $C_4H_7NO_6S_2$, is a very remarkable substance occurring in the bile and in other animal products and tissues. In a state of purity it forms six-sided glistening prisms, which are perfectly transparent, neutral, devoid of odor, readily soluble in hot water, but difficult of solution in cold water, and insoluble in alcohol and ether. It does not enter into combination either with acids or bases. When heated, it undergoes decomposition, and evolves sulphurous acid, in consequence of the sulphur (upward of 25 per cent) which it contains. Taurine occurs naturally in the bile of many animals, including man. As a product of the decomposition of the bile, it may be found in the contents of the intestine and in the excrements; and in cases of jaundice it has been found in the blood, transudations, and urine. Its artificial formation has been noticed in the article *SYNTHESIS*. Its name is derived from the latin *taurus*, a bull, because taurine was first discovered in the bile of the ox.

TAUROMENIUM. See TAORMINA, *ante*.

TAURUS, MOUNT. See ANATOLIA.

TAUSIG, KARL, 1841–71; b. Warsaw; studied music under Liszt, and made a great reputation as a pianist and orchestral director. He was made court pianist at Berlin in 1865. He had an unusual musical memory, and played nearly all the chief compositions of the great masters without notes.

TAUTOG or **BLACKFISH**. *Tautog nigra* or *Americana*, a fish of the family *labridæ* (q. v.), of the section forming the family *cyclo-labridæ* of Müller. It is found in the North American seas, and is in great request for the table. It brings a very high price in the New York market. It attains a size of 12 or 14 lbs. Its color is black on the back and sides; the belly is whitish; both jaws have a double row of strong conical teeth; the face is covered with a scaleless integument. The tautog is caught by hook and line on rocky bottoms. It is sometimes kept in stews to fatten.

TAUTOLOGY (Gr. *tauto*, the same, and *logia*, speech) is a term used to denote the useless repetition of the same ideas in different words. It is considered one of the worst vices, whether of oral or written style, and certainly none more effectually robs language of its force and impressiveness.

TAVERN, a place of entertainment for man and beast, is not a legal term. See *INN*, *PUBLIC-HOUSES*.

TAVERNIER, JEAN BAPTISTE, BARON D'AUBONNE, a celebrated French traveler, was the son of a Flemish engraver who had settled in Paris, and was born there in 1605. The conversation of the savans who frequented his father's shop inspired him with a

ardent curiosity to visit other countries, and prompted him to leave the parental roof before his 15th year. After visiting England, the Low Countries, Germany, Hungary, and Italy, he eagerly caught at the offer made to him by father Joseph (the confidant of Richelieu), to accompany two French noblemen to the east. This journey lasted from Dec., 1630 to the summer of 1633, the line of route passing through Regensburg, Dresden, Vienna, Constantinople (where he left his masters), Erzeroum, Tabriz, Ispahan, Bagdad, Aleppo, and Scanderoon, and thence by sea to Rome. Tavernier then obtained an important post in the household of the duke of Orleans, but received occasional leaves of absence to prosecute his journeys in the east. The *second journey* (1638-43) was from Marseilles to Scanderoon, thence across Syria to Ispahan, south-western Persia, and Hindustan; the *third* (1643-49, through Ispahan, much of Hindustan, Batavia, and others of the East Indies; and in the *fourth* (1651-55), *fifth* (1656-?), and *sixth* (1663-69), various portions of Persia and Hindustan were visited, the outward route being generally by way of Syria and the Arabian desert, and the return one by Asia Minor. Tavernier invariably traveled as a dealer in precious stones and other valuable articles of small bulk, and the great profits he realized strongly impressed upon him the advantages of regular commerce between Europe and the east. On his return to France in 1669 he was graciously received at court by Louis XIV., who presented him with "letters of nobility" in reward for his services to French commerce in India. But his prodigal expenditure and careless generosity speedily reduced his fortune, and the revocation of the edict of Nantes compelled him to take refuge in Switzerland, whence he removed to Berlin, and became director of an East India company which was projected by the elector of Brandenburg. With the view of discovering a road to the Indies through Russia, he set out from Berlin in 1688, but died at Moscow in July, 1689. An account of his travels was written for him by various parties (for Tavernier had no literary qualifications,) and though full of matter valuable to the historian and geographer, it is so ill-arranged as to be in many cases almost unavailable. Tavernier was one of the most remarkable of travelers; wholly devoid of classic sentiment, he traversed the plains of Troy, and passed the ruins of Persepolis without even a flutter of interest, and partly owing to this remarkable condition of mind, his statements are distinguished by an accurate truthfulness little common among travelers. But the chief value of his book lies in the fullness and accuracy with which the nature and state of oriental commerce, the chief markets and commercial routes, and the various systems of coinage and their relations are detailed. Some of his statements concerning the conduct of the Dutch in the East Indies called forth a most virulent and abusive reply from Jurieu, the Protestant theologian, in his *L'Esprit de M. Arnauld* (1684), and a more moderate one from Van Quellenburgh; but all Tavernier's assertions which were of any moment were found to be perfectly correct. His travels were originally published in 3 vols. (two in 1676-77, and the third in 1679); they have since been several times republished, last in 1810, in 7 vols., and have been translated into English (1678, 1684, 2 vols.), Dutch (1682), and German (1684).

TAVIRA, a sea-port t. of Portugal, province of Algarve, 20 m. n.e. of Faros, pleasantly situated at the mouth of the Sequa. Tavira has decayed considerably since 1654, when, it is said, 40,000 people in the town and environs fell victims to the plague. Pop. about 11,000.

TAVISTOCK, a parliamentary borough and market-town of Devonshire, picturesquely situated on the western border of Dartmoor, about 35 m. s.w. of Exeter, in the fertile valley, and on the right bank, of the Tavy (whence its name), which is here crossed by two bridges within the town. Tavistock is a thriving town, with some small manufactures of serges and woolen cloths, iron-foundries and mining-works, copper, lead, tin, and iron being found in considerable quantity in the neighborhood; but the population is chiefly agricultural. It is a place of considerable antiquity, and was formerly of great importance, owing mainly to its abbey, the largest and most magnificent in Devonshire, which was founded in the year 961 for the Benedictine order, by Ordgar, earl of Devonshire, father of the infamous Elfrida, and endowed with many privileges, the abbot being a peer of parliament. At the dissolution, when the revenue amounted to upward of £900, it was bestowed upon John, lord Russell, in possession of whose descendant, the duke of Bedford, the property still remains. A printing-press, the second set up in England, was established in the abbey at a very early period. The refectory and abbey gateway still exist in good preservation. The parish church is a handsome edifice, with a tower at the w. end, resting on arches, under which there is a thoroughfare. The borough sends one member to the house of commons. At the breaking out of the civil war Pym was member for Tavistock. Tavistock is one of the four stannary towns of the co., and is governed by a port-reeve, elected annually; a co. court is held in the town. It is connected with Barnstaple, Launceston, and Plymouth by railway, and with the river Tamar by a short canal. Sir Francis Drake was born in the immediate neighborhood in 1545, and the poet W. Browne in the town in 1590. Pop. '71, of parliamentary borough, 7,725.

TAVOY, the chief t. of a district in Tenasserim, British Burmah, is situated on the left bank of the Tavoy river, about 34 m. from its mouth, in lat. 14°4' n., long. 98°5' e., at the distance of about 220 m. s. of Moulmein. The site of Tavoy, which is low, is

inclosed on three sides by rice-fields, and on the fourth by the river. The houses are scarcely visible from the river—umbrageous trees, palms, plantains, jacks, cassias, and hundreds of flowering shrubs nearly concealing them from view. A wooden-covered pier, supported on piles, forms a convenient landing-place. There is a hospital, a large jail, and a roomy *zayat*, or caravansary. The houses, according to the universal practice of the country, are raised from the ground on piles, and are made of bamboo, fastened with rattan, and thatched with the leaf of the water-palm. Under many of the houses a loom may be observed, at which a female is generally busy at work. The shops are for the most part mere sheds or stalls, and the vendors sit squatted on the raised floor in the midst of their wares. "In this little town," says a recent eye-witness, "Burman life and manners are seen in all their simplicity; and the observer cannot but be struck by the frugality, contentment, happiness, and enjoyment of life manifested by the people." Tavoy is remarkable for its grand annual buffalo-fight. The sport continues for two days, and during that time eight pairs of buffaloes are brought into the field, each animal representing a different district or township. The rice-fields around Tavoy are prolific sources of malaria. Intermittent fevers and dysentery are the most common diseases; but the climate is on the whole healthy, and is not considered inimical to the European constitution. According to the estimates of 1871-72, the population of Tavoy was 14,467. The bulk of these are true Burmans, the balance being made up with Shans and Thongthoos, Karens, Chinese, Malays, and natives of India.

Vessels drawing not more than 12 ft. of water can reach the town of Tavoy by means of the Tavoy river. The anchorage for large ships is at Goodridge plains, about 30 m. below the town.

Tavoy used to be one of the stations in which British troops were settled, but these have been lately withdrawn.

TAX SALES, a public sale of land, according to law, for non-payment of taxes assessed upon it. Some general principles may be stated, as running through the statutes of all or nearly all the states; but as the proceedings are regulated entirely by statute, the rights of the purchasers under, and of the original owners before such sales, the manner in which such sales are conducted, and the regulations in regard to laying taxes differ widely in different states. In the first place the assessed tax must be uncollected upon land unemxempt. The land cannot be legally sold after payment or tender, either by the owner or any person whose interests would suffer by the sale. The statutory provisions before and during the sale must be exactly followed. The tax must have been properly assessed, the proper officer must have attempted to collect it, the sale must be public, duly advertised, take place at the advertised time and place, etc. The land is sold to the highest cash bidder, to whom a certificate is given, entitling him to a deed at the end of the statutory period, during which the owner may redeem, and after which a deed from the state is given to the purchaser. In a majority of the states at present this deed is *prima facie* evidence of the regularity of all the proceedings on the sale. At common law, and by the statutes of some states, it rests upon the purchaser to prove the regularity of such proceedings. In some states it must have been decided by the proper court that the taxes are unpaid, before a sale can take place.

TAX—TAXATION. This term, as expressing the exaction of money from the individual for the service of the state, is familiar to all mankind a step above barbarism; and yet few subjects are surrounded by a greater number of practical difficulties and theoretical niceties. These may be grouped under two sets of considerations—those which affect the justice of a tax, and those which affect its productiveness, and these two often tell on each other. Taxation, indeed, has so frequently been the means of perpetrating political injustice, that the term has fallen into bad popular repute. Whenever the produce of a tax is used otherwise than in the service of those who pay it, the tax is unjust. In its more oppressive form, it has been levied on conquered states, for the benefit of the conquerors, and in this shape it has sometimes been called tribute. The direction which all constitutional struggles to cleanse taxation from injustice have taken has been that of self-taxation, the community as a whole deciding on what it requires to take from the individual members for the public service. The accomplishment of this has been the chief object of all the struggles which have made a free constitution for the British empire. There were old feudal dues which the monarchs had the power of exacting; but when these were insufficient for their ambitious projects, they had to ask parliament for a supply, and parliament generally took the opportunity of granting it to demand redress of grievances. It came thus to be a fundamental constitutional doctrine, that no tax can be levied save by the consent of the representatives of the people who have to pay it. The constitutional doctrine thus created by Britain was remembered by the American colonies when Mr. Grenville sought to raise there a stamp-duty and a customs-duty on tea, and the colonies revolted under the celebrated cry that "taxation without representation is tyranny!"

It was discovered, in the course of the long struggle of the house of commons to keep its hold on the purse, that the least afflictive of taxes may be the most dangerous. A fixed land-tax comes, for instance, to be no impost at all, in the afflictive sense of the term. If a thousand a year have been drawn off a certain acreage of land from time immemorial, the proprietors never possessed that part of the rents, and are no more

sufferers from not having them than from not possessing their neighbors' estates. A government with a large revenue of this kind, however, will certainly be inimical to freedom. The time when the liberties of England were in the greatest danger was the twelve years of Charles I.'s reign in which he was able to get on without going to parliament for money. The extravagance of sovereigns who wasted the domains of the crown has generally prevented them from having too formidable an influence by the possession of independent incomes. In Britain, this difficulty has been effectually guarded against, and any of the expenses of the crown which can now be paid without going annually to parliament for a vote of supply are of a very trifling character.

How to make taxation productive, is a vast and complicated practical science. Turgot, one of the wisest of financiers, called it the art of plucking the goose without making it cry. The most ingenious devices to this end, however, have often, in practice, met with counteracting difficulties. It was supposed that indirect taxation—that is, a duty levied on articles before they reach the consumer, must, in a civilized and orderly country, be almost inexhaustible. The merit of the system lay in the consideration, that the burden of the tax did not fall on the person who paid it. Income-tax, house-tax, dog-tax, and the like are levied directly on the person on whom the burden ultimately falls, and if he do not pay, the amount will be taken by force. Tea-duty, sugar-duty, and wine-duty, however, are not levied on the consumer, though he has to pay them; they are levied on the importer, who has no, or a very slight, interest against the tax, since he must charge it on the consumer. But this form of taxation is met by checks. If it is excessive, people will not buy the taxed article; and it has often been found that reducing the duty increases the revenue. An indirect tax on luxuries, and especially on those which may be used to vicious excess, has strong recommendations. In some cases, it is no great calamity should the tax throw the article nearly out of use. But then comes another check in the smuggler, whose profession may probably do more to corrupt and disorganize society than the free use of the article in which he deals. A tax on the necessities of life, on bread or salt, cannot be evaded, as in the case of luxuries, by the abandonment of use, and therefore it is very productive, but it is also very oppressive. The tax on salt in France was one of the chief causes of the French revolution. The happiest condition for the revenues of a country is when luxuries are so abundantly used by all classes that a small addition to their price is a slight burden, yet yields a large revenue. In this country, the revenue thus derived from tea, sugar, and stimulants may be set down in round numbers at 30 millions. The chief taxes which now form the revenue of Britain are—1. Those by old custom called "assessed," and levied upon certain items in the possessions and enjoyments of the citizen, as his house-domestics, horses, dogs, and armorial bearings. 2. The property and income tax, which, after long disuse, was renewed in 1842, and is raised from time to time according to the exigencies of the government. 3. The customs. 4. The excise. 5. The stamps and post-office; and 6. The land tax. See CUSTOMS-DUTIES, EXCISE, POST-OFFICE, STAMPS, LAND-TAX, FINANCE.

TAX—TAXATION (*ante*). The constitution of the United States vests in the general government the right of imposing taxes upon the people so far as duties on imports or exports are concerned; also requires that all bills for raising revenue shall originate in the house of representatives. No state is permitted to lay any impost or duty on imports or exports (except what may be necessary for executing its inspection laws) without consent of congress; and the net produce of all such duties and imposts is required to be for the use of the treasury of the United States. But no tax or duty can be laid by congress on articles exported from any state; nor can any capitation or other direct tax be laid, except in proportion to the authorized census or enumeration. The systems of taxation in the United States are therefore two in number: that of the national government; and that observed by the state governments, each in its sovereign capacity. Taxation by the national government is required to be uniform throughout the country; and direct taxation from this source must be apportioned to the states in accordance with their respective population. Until the war of the rebellion the national government relied wholly on duties on imports for funds to carry on the government; but from that time it has been found necessary to add to this source of income taxation on various domestic manufactures; and during the war an income tax was imposed. The existing internal revenue taxes are placed upon the capital and circulation of banks; on beer, ale, wines, whisky, cigars, tobacco, patent medicines, cosmetics, etc.; on matches, wax-tapers, cigar-lights, etc. The table on the opposite page shows the receipts of the United States by taxation from March 4, 1789, to June 30, 1879.

State taxation is direct, and is either through poll-taxes upon individuals, or by assessment upon property. Not all the states levy poll-taxes, the plan being obnoxious to many. Taxation upon real estate is levied through assessment by duly appointed assessors, on proper estimates made by these officials. The custom is to assess real estate at from one-quarter to one-half its market value. Local taxes in counties, towns, cities, and school-districts are levied in accordance with general statutes or by special charter, and are apportioned in accordance with the state valuation, except as to improvements in cities, which are made chargeable on adjoining property. Taxation on personal property is levied on returns made by the persons or corporations in question. In the neces-

sary legislation toward an equitable system of taxation, certain exemptions are made, including the following: property belonging to incorporated institutions of learning endowed by private individuals; houses of worship and certain other church property; public cemeteries; personal property sufficient to cover the necessities of life; and public property, both state and national; public lands, custom-houses, school-houses, court-houses, parks, etc. The propriety of extending freedom from taxation to institutions of learning and church property is often brought in question, and powerful arguments have been employed on both sides. Inasmuch as it is very largely considered from a sentimental point of view, it is improbable that any change will soon be made on this question.

SUMMARY OF INTERNAL REVENUE RECEIPTS, FROM ALL SOURCES, FOR SEVENTEEN YEARS, 1863-79.

YEARS.	Spirits.	Tobacco.	Ferment- ed Liquors.	Banks and Bankers.	Penalties, etc.	Adhesive Stamps.	Articles and occupations formerly taxed but now exempt.

The total cost of collecting internal revenue in the United States for the fiscal year ended June 30, 1879, was as follows:

For salaries and expenses of collectors, including pay of deputy collectors, clerks, etc.	\$1,822,000 00
For salaries and expenses of revenue agents, surveyors of distilleries, gaugers, and storekeepers.....	1,650,000 00
For dies, paper, and stamps.....	381,500 00
For salaries of clerks, officers, and employees in the office of the commissioner of internal revenue.....	253,330 00
For expenses of detecting and punishing violations of internal revenue law.....	100,000 00
Total cost.....	\$4,206,830 00
Total collections (not including commissions on sale of stamps).....	\$113,449,621 38
Cost per cent.....	3.73

Experience has shown that taxes are least easily collected when reliance is to assessment has to be made on personal statements as to amount of taxable values; and when, as is the case in regard to distilled spirits, the temptation to illicit manufacture is great, or, as is the case in regard to cigars and other articles which admit of ready concealment, the element of smuggling enters into the question. Stamp duties are found to be the least onerous, the most easily collected, and to press the most equally in all directions, thus avoiding special occasion for irritation.

TAXATION OF COSTS is the checking or reviewing of the charges made by attorneys or solicitors for legal business; and there is an officer of the court provided for the purpose, called in England a master or a taxing-master, or a registrar, according to the nature of the court; in Scotland, he is called an auditor. Solicitors differ from all other professions in this, that they are treated as officers of the court, and they are not at liberty to charge what prices they please for the various services they perform. Hence, every step in a suit has a certain value put upon it by the court, and the business of the taxing-officers is to see that this standard is not transgressed. There are many exceptional matters, however, which arise in every suit, which often cause difficulty in apportioning a proper amount of remuneration, the taxing-officer having considerable discretion. In consequence of a taxing-officer being provided by the court, it is a right which every client of a solicitor has, if not satisfied with the bill of costs delivered to him, to have it referred to the taxing-officer to be taxed. But in general, this must be done without delay. If the taxing-officer certify that more than one-sixth too much has been charged, then not only is the client not bound to pay the excess, but the expense of the taxation must be borne also by the solicitor; whereas if less than one-sixth is taxed off, the client has to bear the expense of taxation. Not only are the expenses of a suit liable to taxation, but other kinds of miscellaneous business which a solicitor does as a solicitor. It has often of late been made matter of complaint that solicitors are not allowed

to fix their own charges, or to agree with clients upon an arbitrary charge, or a charge by commission, the tendency of the present system being to make the solicitor anxious to eke out his remuneration by lengthening the proceedings, so as to make a basis for chargeable items; but the legislature has steadily rejected hitherto all attempts to abolish the check provided by taxation.

TAXEL. See **BADGER**.

TAXICORNÉS, a family of coleopterous insects, of the section *heteromera*, having the body generally square; the thorax either concealing or receiving the head; the antennæ short; the legs adapted for running. Most of them are found in fungi and beneath the bark of trees. They are widely distributed over the world.

TAXIDERMY, the art of preparing the skins of animals for the purposes of the naturalist. The chief means employed in preparing the skin for stuffing in the case of small animals is to remove it carefully from the body, and, having cleaned away from it any adherent flesh, etc., to anoint it with arsenical soap; for the making of which there are several formulae, the following being the most used: arsenic, 1 ounce; white soap, 1 ounce; carbonate of potash, 1 dram; distilled water, 6 drams; camphor, 2 drams. This keeps the skin supple, and prevents decay and the attacks of insects. The larger skins are generally prepared with a composition called preservation powder, which is made of the following ingredients: arsenic and burnt alum, each 1 lb.; powdered oak-bark, 2 lbs.; camphor $\frac{1}{2}$ lb. These substances are all reduced to a powder, mixed, and passed through a fine sieve. It requires to be carefully kept in well-stoppered bottles or jars, and when used, is thickly sprinkled over the flesh-side of the skin while still wet, and must be thoroughly rubbed in. Gloves should always be worn in this process to prevent danger from the poisonous compound. Some skins are prepared with alum only, and others with the oak-bark liquor of the tanner's pits. This, in the case of very large skins, answers very well.—Besides the mere preparation of the skin, the art of taxidermy is held to mean also the stuffing and mounting of them. This requires much personal experience, and as almost every group of animals must be treated differently, it is impossible to explain the various methods fully in this short notice. Various works have been written upon the subject.

TAY, the largest river in Scotland, draining nearly the whole of Perthshire (q.v.), and pouring into the German ocean a greater bulk of water than any other British river, has its source in the western part of the county of Perth. The Dochart, the principal feeder of loch Tay, rises in Ben Lui, on the borders of Argyle-shire, and flowing in a n.e. direction, is joined by the Lochy, just before the united streams enter the lake. After leaving it, the Tay flows for some distance e.n.e., when turning southward, it passes, with a very winding course, Dunkeld (q.v.), and Perth (q.v.); about a mile below the latter place, it again changes its direction to e.n.e., widening at the mouth of the Earn (q.v.) into an estuary—the firth of Tay—which varies from three-fourths of a mile to three m. in breadth, and lies mostly between the counties of Fife and Forfar, joining the German ocean about 10 m. below Dundee (q.v.). From the n. and e., the Tay receives the Lyon, the Tummel, and Garry, and the Isla; and from the w., the Almond and the Earn; its entire basin comprises an area of about 2,500 sq. miles. The salmon-fishings on the Tay and its tributaries are of considerable value. The Stormontfield ponds for the propagation of salmon are 5 m. above Perth. The tide flows up the river to about a mile above Perth, to which place it is navigable by vessels of 100 tons; and to Newburgh, about 20 m. from its mouth, by vessels of 500 tons; the navigation up to Dundee, notwithstanding the many precautions which have been taken, is attended with very great difficulty, on account of the numerous and shifting sand-banks.

Loch TAY is a long and narrow lake, picturesquely situated in a basin scooped out of the bosom of the mountains, 355 ft. above the sea-level, in length about 15 m., and average breadth 1 m., varying from 100 to 600 ft. in depth. Ben Lawers (q.v.) lies on its w. side. The loch is at times subject to violent and unaccountable agitations.

TAYLER, JOHN JAMES, D.D., 1798-1869; b. England; graduated, university of Glasgow, 1818; minister of a Unitarian congregation at Manchester, 1820; professor of church history, subsequently of theology, in the dissenting college at Manchester; principal of the college after its removal to London, taking the name of Manchester new college; was co-pastor with rev. James Martineau of the Unitarian congregation in Little Portland street. He published *Retrospect of the Religious Life of England*; *Christian Aspects of Faith and Duty*; *Attempt to Ascertain the Character of the Fourth Gospel*; *Catholic Christian Church the Want of Our Time*.

TAYLOR, a co. in n. Florida; bounded on the s.w. by the gulf of Mexico; drained by the Aucilla and the New rivers; about 1100 sq.m.; pop. '80, 2,279—165 colored. The surface is level, and well timbered. The soil is fairly fertile. The principal productions are corn, cotton, and sugar-cane. Co. seat, Perry.

TAYLOR, a co. in w. central Georgia; drained by the Flint river, which bounds it on the n.e., and by Whitewater creek; traversed by the South-western railroad; about 425 sq.m.; pop. '80, 8,595—3,826 colored. The surface is even, and heavily timbered. The soil is fertile. The principal productions are corn, cotton, live stock, and lumber. Co. seat, Butler.

TAYLOR, a co. in s.w. Iowa; drained by Platte river, river One Hundred and Two, and Honey creek; about 525 sq.m.; pop. '80, 15,635—14,842 of American birth. The surface is rolling prairie or wood-land. The soil is fertile. The principal productions are wheat, oats, corn, grass, and cattle. Co. seat, Bedford.

TAYLOR, a co. in s. central Kentucky; watered by Robinson's creek and the Green river; about 300 sq.m.; pop. '80, 9,260—1,899 colored. The surface is rolling. The soil is fertile. The principal productions are corn, oats, rye, tobacco, and cattle. Co. seat, Campbellsville.

TAYLOR, a co. in n.w. central Texas; drained by a branch of the Brazos river, about 850 sq.m.; pop. '80, 1736—1712 of American birth. The surface is level with little timber. Cattle grazing is the principal occupation. Co. seat, Buffalo Gap.

TAYLOR, a co. in n. West Virginia; drained by Tygart's Valley river, traversed by the Baltimore and Ohio railroad; about 165 sq.m.; pop. '80, 11,454—10,998 of American birth. The surface is hilly and heavily wooded. The soil is only partially fertile. The principal productions are wheat, corn, oats, and live stock. There are deposits of bituminous coal. Iron is found, and there are foundries and machine-shops. Co. seat, Grafton.

TAYLOR, ALFRED SWAINE, b. Kent, England, 1806; studied medicine at Guy's and St. Thomas's hospitals and in the best schools of Europe; and in 1830 became a member of the Royal college of physicians and surgeons. In 1845 he was made professor of medical jurisprudence at Guy's, a position he still holds. He is the author of works on chemistry, on poisoning, and on medical jurisprudence, and has often been consulted by the government in important criminal cases. He became a fellow of the Royal society in 1845.

TAYLOR, BAYARD, an American author and traveler, born at Kennett Square, Chester co., Penn., Jan. 11, 1825. Having received a common school education, he was apprenticed at 17 in a printing-office, when he began his poetical contributions to periodicals. In 1844 he published a volume of poems under the title of *Nimrod*, and soon after started on a pedestrian tour of Europe, and in 1846 published *Vicars Afoot, or Europe seen with a Knapsack and Staff*. After his return he edited a country newspaper, then went to New York, and wrote for the *Literary World* and *Tribune*. Of the latter he became assistant-editor, and as its correspondent, made extensive travels in California and Mexico, recorded in *El Dorado, or Adventures in the Path of Empire*, 1850; up the Nile to lat. 12° 30' n., and in Asia Minor, Syria, across Asia to India, China, and Japan—recorded in his *Journey to Central Africa, Lands of the Saracen, and Visit to India, China, Loo-Choo, and Japan* (1853). Later explorations are recorded in *Northern Travel, or Summer and Winter Pictures of Sweden, Denmark, and Lapland* (1856); and *Travels in Greece and Russia, with an Excursion to Crete* (1857). In 1862-63 he was connected with the embassy at St. Petersburg; and in 1874 he visited Iceland. He resided some years in Germany, and in 1878 was appointed United States ambassador at Berlin, where he died in Dec., 1878. In 1848 he published *Rhymes of Travel, Ballads, and other Poems*; *Book of Romances, Lyrics, and Songs* (1851); *Poems of the Orient* (1854); *Poems of Home and Travel* (1855); *At Home and Abroad* (1859-62); *Hannah Thurston*, a novel (1864); *Beauty and the Beast*, and *The Masque of the Gods* (1872); *The Prophet, a Tragedy* (1874); *Home Pastorals*, etc. (1875); *Prince Deukalion*, a drama (1878). He translated *Faust* in 1871, and for the last twelve years of his life was engaged upon a life of Goethe.

TAYLOR, BAYARD (*ante*), 1825-78, b. Penn. In 1851 Mr. Taylor set out on an extended journey in the east, and afterward traveled extensively through Asia Minor, Syria, and Europe. In 1852 he crossed Asia to Calcutta, and went to China where he joined the expedition of commodore Perry to Japan. In 1862-63 he was secretary of legation at St. Petersburg, and later *chargé d'affaires*. In 1874 he revisited Egypt, and attended the millennial celebration in Iceland. For this occasion he wrote a poem, which was translated into Icelandic and read at the celebration. In Feb., 1878, he was appointed minister to Germany, where his reception was enthusiastic, and his death at the end of the same year was greatly regretted. His translation into English of Goethe's *Faust* is considered his finest contribution to literature. Among his later works are *The National Ode*, read at Philadelphia, July 4, 1876; *Boys of Other Countries; Stories for American Boys* (1876); *The Echo Club, and other Literary Diversions* (1876); *Prince Deukalion* (1878).

TAYLOR, BENJAMIN C., D.D., 1801-81; b. Philadelphia; graduated at Princeton college, 1819; began the study of theology with the rev. Dr. John M. Mason, New York, and completed his course at the theological seminary of the Reformed church, New Brunswick, N. J.; pastor of the united churches of Greenbush and Blooming Grove, N. Y., 1822-25; accepted a call to Passaic, N. J.; became pastor of the Reformed church of Bergen, N. J., 1828; relieved from active duties, 1870, and made *pastor emeritus*. He published *Annals of the Classis and Township of Bergen*, and some sermons. He had great faithfulness and symmetry of character, and was venerated in his own denomination and in other communions.

TAYLOR, BROOK, a celebrated English mathematician, was born at Edmonton, in Middlesex; Aug. 18, 1685, of a Puritan family of good position; entered St. John's college, Cambridge, in 1701, at a time when mathematical science was the prominent pursuit among the learned; took his degree of LL.B. in 1709; became a fellow of the Royal society in 1712, and its secretary in 1714, in which latter year he also took the degree of LL.D. Though so young, he had become widely known in Britain and on the continent for great proficiency in mathematical knowledge, and power and versatility of mind, having already written various valuable treatises on capillary action, on the vibration of a string, on music, etc. In 1716 he visited Paris, and was received with warm demonstrations of regard by the French savans, who respected his ability and learning, and the prominent and distinguished part he had taken in the Leibnitzian controversy. On his return to England in 1717 he resumed his habits of severe study, but was forced by declining health to resign the secretaryship in 1718. For the next three years he wandered about, residing now on the continent, now in England. He died, Dec. 29, 1721, at the age of 46. Besides his earlier works above mentioned, he contributed a series of able papers on higher algebra, dynamics, and general physics, published separately his *Methodus Incrementorum* in 1715, and a *Treatise on Linear Perspective*, the first general exposition of this subject, in 1719. During the last ten years of his life he gave himself up almost entirely to metaphysical and biblical studies. His *Methodus Incrementorum* contains, besides the famous "theorem" (see TAYLOR'S THEOREM), the first germs of the calculus of finite differences, various now common forms of infinitesimal series, with mechanical, physical, and algebraical applications. The chief use made by Taylor of his theorem is in a paper (1717) entitled "Method of Approximation to the Roots of Equations." The results of his investigations may be found in the *Phil. Trans.* (1713-23), and in his two works above mentioned.

TAYLOR, CHARLES, D.D., b. Mass., 1819; graduated at university of New York, 1840; taught, S. C., 1841-44; joined Methodist Episcopal conference, 1844; took medical degree at Philadelphia, 1848; went the same year a missionary to China; returned to America, 1854; was professor in Spartanburg female college, 1855-57; its president, 1857-58; Sunday-school secretary of M. E. church, south, 1858-62; president of Wesleyan university at Millersburg, Ky. He published *Five Years in China*, and numerous articles in periodicals.

TAYLOR, EDWARD T., 1794-1871; b. Va.; was a sailor in his youth; was captured on a privateer in the war of 1812; in prison at Dartmoor, England, and chaplain to the prisoners; was ordained a preacher in connection with the New England Methodist Episcopal conference, 1819; became minister of the Seamen's Bethel, 1828. He was greatly distinguished as the sailor's preacher, and had great influence over his rough auditors by his warmth of heart, native wit, and natural eloquence. His common designation was "father Taylor." He visited Europe in 1832 and Palestine in 1842; was chaplain to the U. S. frigate sent with relief to Ireland during the famine in 1846.

TAYLOR, GEORGE, 1716-81; b. Ireland; received a fair education, and emigrated to the United States in 1736. He was at first a common laborer in a Pennsylvania foundry, but quickly rose, and in time became a large proprietor of iron foundries in Northumberland county. In 1764 he was chosen a member of the colonial assembly, and later served in the provincial assembly for five years. He was active in aiding the movements which led to the revolution, and in 1776 became a member of the continental congress. He signed the declaration of independence, though he was not a member of the congress until after it was passed. The latter part of his life was spent in Delaware.

TAYLOR, ISAAC, 1759-1829; b. London; originally a line-engraver, he removed from the metropolis, 1786, to Lavenham, Suffolk, to pursue his profession and train his children in a quiet country town; became minister of an Independent church, Colchester, Essex, 1790-1810, and at Ongar from 1810 until his death. Among his publications were many on educational subjects.

TAYLOR, ISAAC, b. at Lavenham, in Suffolk, 1787, d. at Stanford Rivers, in Essex, 1865, eminent as a Christian philosopher, artist, and mechanic, was the third of his name who attained distinction—his grandfather and father (known as Isaac Taylor of Ongar) being both named Isaac, and each in his way distinguished. Charles Taylor, the editor of *Calmet*, was an uncle, and Jane Taylor (author of the *Q. Q. Papers*) and Ann Taylor (Mrs. Gilbert of Nottingham), joint-authors of *Hymns for Infant Minds*, were sisters of the subject of this article. The literary career of Isaac Taylor extended over nearly half a century. It began in 1818, in contributions to the *Eclectic Review*, for which Robert Hall, John Foster, and Josiah Conder then wrote, and ended in 1865, in contributions to *Good Words*, in which the name of the veteran figured with those of men who were unborn when he was in the height of his reputation. Between 1822 and 1827 he published *Elements of Thought; Characters of Theophrastus*, with illustrations, etched by himself; *The History of the Transmission of Ancient Books to Modern Times*; *The Process of Historical Proof*, a translation of Herodotus, and the *Memoirs and Correspondence of Jane Taylor*, his sister, who has already been mentioned. In 1829 he published, anonymously, *The Natural History of Enthusiasm*, which ran rapidly through several editions; and between 1829 and 1836 he published in succession *Fanaticism*,

Spiritual Despotism, *Saturday Evening*, and *The Physical Theory of Another Life*. In 1836 appeared *Home Education*. Thereafter he was a long time occupied upon a new translation of Josephus, undertaken jointly with the rev. Dr. Traill, and which was illustrated by etchings executed by himself. Within the last 13 years of his life appeared *Loyals, Wesley, The Restoration of Belief, Logic of Theology, Ultimate Civilization*, and *The Spirit of Hebrew Poetry*. Besides these numerous works, Isaac Taylor wrote many articles for the graver quarterly reviews, which are as yet uncollected. He had been educated as an artist, and some of his designs, executed before he betook himself chiefly to literature, have evoked the warmest praise from the most scrupulous critics, who have wondered how one with such a genius for art could have deserted it. It would be impossible to give here any account that would be intelligible of his numerous mechanical inventions; it must suffice to say that, by two of his inventions, he revolutionized the art of calico-printing. Isaac Taylor married in middle life, and had a large family, whose home education, as liberal-minded but pious Christians, was among, and not one of the least of, the tasks of his life.

TAYLOR. The rev. ISAAC, M.A., vicar of Holy Trinity, Twickenham, and eldest son of the preceding, was b. at Stanford Rivers, Mar. 3, 1829. He is the author of *The Liturgy and the Dissenters*, and one or two other theological pamphlets; but has best maintained the literary distinction of his family by his works on philology. His *Words and Places, or Etymological Illustrations of History, Ethnology, and Geography* (1864), of which a second edition, revised and enlarged, was published in 1865, is a work of great research as well as erudition, and has done more toward the elucidation of the local names of English places than any book yet published. In *Etruscan Researches* (1874) Taylor tries to prove that the Etrurians were allied to the Turkish or Mongolian races. This proposition, however, is not well established, and the work has received severe handling from critics, especially from prof. Max Müller. In 1876 Taylor published *The Etruscan Language*.

TAYLOR, ISIDORE SÉVERIN JUSTIN, Baron, b. Brussels, 1789; studied art and became a writer and artist. Politically he sided with the Bourbons, and served in the Spanish campaign of 1823. The obelisk of Luxor now in the *Place de la Concorde*, Paris, was brought from Egypt by him. Baron Taylor has acted as purchaser of pictures for many of the great French collections, is a grand officer of the legion of honor and has written several dramas and treatises on art and kindred subjects.

TAYLOR, JEREMY, one of the greatest names in the English church, was the son of a Cambridge barber, and was born in that town, Aug. 15, 1613. At the age of 13 he entered Caius college as a sizar, and after seven years' strenuous and brilliant study in classics and theology, took the degree of M.A. Like archbishop Usher, he was admitted to holy orders before he had reached his 21st year. Soon after, he attracted the notice of Laud (who had a regard for learning, if none for liberty), and was preferred by him to a fellowship at All Souls, Oxford (1636). About the same time, he was appointed chaplain in ordinary to the king; and in 1638, rector of Uppingham, a preferment which he retained till the successes of the parliamentarians deprived him of it. The first notable publication of Taylor's was a defense of the church, entitled *Episcopacy asserted* (Oxford, 1642). It procured for him the honor of D.D. During the next three years, Taylor probably accompanied the royal army; but when fortune had unmistakably declared against the king he withdrew into Wales (1645-46), and, in conjunction with Mr. W. Wyatt of St. John's college, Oxford, opened a school at Newton, in Caermarthenshire. It appears to have been a pretty successful adventure, and many of his scholars, we are told, "having, as it were, received instruction from this prophet in the wilderness, were transplanted to the universities." Taylor also found a patron in the earl of Carbery, who was then living at the family seat of Golden Grove, in the same county, and who appointed him his domestic chaplain. But if this period of Taylor's life had become to the outward eye obscure and mean, it is rendered illustrious by the splendor of his literary achievements. Between 1647 and 1660, the long 13 years of his enforced seclusion, appeared all his great works, and remembering their unsurpassed merits, we are almost disposed to feel grateful to those who expelled him from his rectory, and drove him to strictly literary pursuits. In 1647, was published the *Liberty of Prophesying*, a work written on behalf of the clergy of the church of England, who were being expelled from their livings by the victorious Puritans, but in which the pleadings are based on principles far more comprehensive and tolerant than the age was disposed to acknowledge; in 1650, the *Life of Christ* (2 vols.), one of the most popular of his productions, and *The Rule and Exercises of Holy Living*; in 1651, *The Rule and Exercises of Holy Dying*, a portion of his *Sermons*, and the *Discourse of the Divine Institution, Necessity, and Sacredness of the Office Ministerial*; in 1652, a *Discourse on Baptism, its Institution, and Efficacy upon all Believers*; in 1653, 25 additional *Sermons*; in 1654, *The Presence Real and Spiritual of Christ in the Blessed Sacrament*; in 1655, *The Guide of Infant Devotion, or the Golden Grove*, and the *Unum Necessarium, or the Doctrine and Practice of Repentance*, a decidedly Pelagian treatise, which involved him in a considerable controversy; in 1657, a *Collection of Polemical and Moral Discourses*, a *Discourse on Friendship*, etc.; and in 1660, his famous *Ductor Dubitantium, or the Rule of Conscience in all her General Measures*, the most learned,

subtle, and curious of all Taylor's works. It was dedicated to Charles II. He was a staunch royalist, a splendid scholar, a consummate theologian, and a man of wonderful literary genius, and so it was in the nature of things almost impossible that he should escape preferment. Before 1660 had expired, he was elevated to the bishopric of Down and Connor, a dignity which he only retained some seven years, dying Aug. 13, 1667. Taylor was not happy in his Irish see. Before a year was over, he was anxious to be delivered from it as from a "place of torment." The Scotch Presbyterian ministers were "incendiaries"—they robbed him of the "people's hearts;" they even "threatened to murder" him; his only hope was in the government and the military. Altogether, it is a melancholy spectacle to behold the finest ecclesiastical genius of the time half broken-hearted by petty squabbles with intolerable fanatics, who had, nevertheless, in the points at issue between them and Taylor, something like justice on their side. No modern mind would hesitate for an instant to acknowledge that the Scoto-Irish Presbyterian clergy were perfectly entitled to act as they did, and yet we fear it is too plain that the good bishop would have gladly seen them prohibited by an Episcopalian soldiery. Nay, the author of the *Liberty of Prophesying* went a step further; and on one occasion, only three months after his consecration, actually deposed 36 Presbyterian ministers occupying livings which the restoration had inconsiderately and tyrannically declared to be Episcopalian. Some very interesting information in regard to this all but unknown period of Taylor's life is to be found in *Notes and Queries* (Nov. 11, 1865).

Taylor, sometimes styled the modern Chrysostom (q. v.), on account of his golden eloquence, has no equal in the whole series of ecclesiastical writers for richness of fancy. All other divines—patristic, mediæval, and modern—show poor and meager beside him in this respect. Some are more logical, or penetrating, or profound; some grasp more clearly the spiritual significance of doctrine, or display a deeper knowledge of human nature; but Taylor ranks among the first men of his age in point of learning, subtlety of argument, elevation of devout feeling, and philosophic largeness of view, while his inexhaustible imagery, shining "like the glossy purples of a dove's neck," and full of all tender and pathetic beauty, reminds us of Spenser and Shakespeare, of Sidney and Fletcher, rather than of the somber order of theologians.—The best edition of Taylor's works is by the rev. C. P. Eden, M.A., fellow of Oriel college, Oxford (10 vols., London, 1854).

TAYLOR, JOHN, 1580–1656; b. England; a waterman on the Thames, commonly called "the water poet." He tells, in *The Pennyless Pilgrimage, or the Moneyless Perambulation of John Taylor, alias the King's Majesty's Water Poet*, "how he traveled on foot from London to Edinburgh, not carrying any money to or fro, neither begging, borrowing, or asking meat, drink, or lodging." He complains of his treatment in these frolics in his *Scourge for Baseness*. He collected in 1630 *All the Works of John Taylor, the Water Poet*.

TAYLOR, NATHANIEL WILLIAM, D.D., 1786–1858; b. Conn.; graduated at Yale college, 1807; studied theology five years with Dr. Dwight; ordained pastor of the First church (Congregational), New Haven, 1812, as successor of Moses Stuart; elected Dwight professor of didactic theology in Yale college, 1822, holding the position till his death, having in 36 years given instruction to 700 students preparing for the ministry. While a pastor he wrote a series of articles for the *Monthly Christian Spectator* on the Unitarian controversy. In 1828 he preached in New Haven the *concio ad clerum*, presenting views on native depravity which were denounced as heretical, and led to a protracted discussion between him and Dr. Tyler. After his death, four volumes of his works were edited by president Noah Porter: *Practical Sermons; Lectures on the Moral Government of God*, 2 vols.; *Essays, Lectures, etc., upon Select Topics in Revealed Theology*. The views for which he was attacked would now scarcely give rise to any controversy. He was a man of acute intellect and deeply evangelical spirit.

TAYLOR, RICHARD, b. Florida; son of president Zachary Taylor. At the beginning of the rebellion he joined the confederate army, and commanded a Louisiana regiment at the battle of Bull Run. He served under Jackson in Virginia, with Kirby Smith in the trans-Mississippi department, and defeated Banks in the latter's Red River expedition. In 1864, then ranking as maj. gen., he took command of the east Louisiana department and surrendered in 1865 to gen. Canby. He is a brother-in-law of Jefferson Davis. Since the war he has resided in Louisiana.

TAYLOR, SAMUEL HARVEY, LL.D., 1807–71; b. New Hampshire; graduated at Dartmouth, 1832, and Andover theological seminary, 1837; tutor at Dartmouth, 1836–37; principal of Phillips academy, Andover, until his death. He was unsurpassed for thoroughness as a classical teacher. From 1852 he was one of the editors of the *Bibliotheca Sacra*. Among his publications are: *Methods of Classical Study; Krab's Method for Writing Latin*, from the German; *Kühner's Elementary Grammar of the Greek Language*, from the German; *Memoir of the Rev. Edward L. Parker*.

TAYLOR, STEPHEN WILLIAM, LL.D., 1791–1856; b. Mass.; graduated at Hamilton college, 1817; taught the Black River academy at Lowville, N. Y., 14 years; teacher of a private school 3 years; took charge in 1834 of the preparatory department of Hamilton institution; was professor of mathematics and natural philosophy there, 1838–45; was its president after it was organized as Madison university in 1851.

TAYLOR, THOMAS, 1758-1835; b. London; generally known as the Platonist; spent three years at St. Paul's school; afterward became pupil to the rev. Mr. Worthington, a classical scholar, intending to prepare for the ministry. But a premature marriage and pecuniary difficulties compelled him to relinquish study for the ministry, and he became clerk in a banking house, afterward assistant-secretary to the society for the encouragement of arts, manufactures, and commerce, devoting his spare time to the study of Greek literature and the elucidation of the Platonic philosophy. He delivered a course of lectures on the Platonic philosophy, and taught some pupils the languages and mathematics. He determined to translate all the untranslated works of the ancient Greek writers. The duke of Norfolk and a retired tradesman, Mr. Meredith, published his translations of Plato, Aristotle, and other Greek writers. His writings number in all 38 distinct works; some of them, as the Plato and Aristotle, consisting of 5 and 9 vols. respectively. Besides his translations of Greek writers, he published works in other departments.

TAYLOR, TOM, 1817-80; b. England; educated at Glasgow and Cambridge. He was for two years professor of the English language and literature at University college, London; was afterward called to the bar, and for the next 21 years held various government offices. He was the author of nearly 100 dramatic pieces, among the most popular of which are: *Still Waters Run Deep*; *The Overland Route*; *Victims*; *'Tis Not an Axe and Crown*; and *The Ticket-of-Leave Man*. He was a frequent contributor in prose and verse to *Punch*, of which he was for some time editor.

TAYLOR, WILLIAM J. R., D.D., b. N. Y., 1823; son of Dr. Benjamin C.; graduated at Rutgers college, New Jersey, 1841, and at the theological seminary of the Reformed church, New Brunswick, 1844; pastor of Reformed church, New Durham, N. J., 1844-46; Jersey City, 1846-49; Schenectady, 1849-52; Third Reformed church, Jersey City, 1852-54; Third Reformed church, Philadelphia, 1854-62; corresponding secretary American Bible society, 1862-69; pastor Clinton street Reformed church, Newark, N. J., 1869; president of general synod of Reformed church, 1871; editor-in-chief of *The Christian Intelligencer*, 1872-76. His church in Newark is one of the leading churches in the city.

TAYLOR, WILLIAM MACKERGO, D.D., b. Scotland, 1829; graduated at university of Glasgow, 1849; studied theology in Edinburgh; ordained pastor of the United Presbyterian church at Kilmaurs, 1853; pastor of the United Presbyterian church at Derby road, Liverpool, 1855; came to the United States, 1871, as delegate of the United Presbyterian church of Scotland to the general assembly of the Presbyterian church at Chicago; became pastor of the Broadway Tabernacle church (Congregational), New York, 1872. He received the degree of D.D. from Yale college and Amherst the same day. He has published *Life Truths*; *The Miracles: Helps to Faith, not Hindrances*—a reply to Renan's *Life of Jesus*; *The Lost Found, and Wanderer Welcomed*; *Memoirs and Remains of Rev. M. Dickie*, Bristol; *David, King of Israel*; *Elijah the Prophet*; *The Ministry of the Word*. He has delivered a course of lectures in Yale divinity school on the "Lyman Beecher foundation." His preaching draws a large and attentive congregation.

TAYLOR, WILLIAM ROGERS, b. R. I., 1811; entered the U. S. navy in 1828. During the Mexican war he was on the sloop *St. Mary's*, and took part in the engagement at Tampico Bar, and the siege of Vera Cruz. He served in the war of the rebellion, participated in the attacks on forts Wagner and Sumter, 1863, and afterward in the attacks upon fort Fisher. He was made rear-admiral in 1871.

TAYLOR, ZACHARY, 12th president of the United States, was born in Orange co., Va., Nov. 24, 1784, son of col. Richard Taylor, an officer of the war of independence, and one of the first settlers of Louisville, Ky., where Taylor was taken in early childhood, and grew up to his 24th year, working on a plantation, with only the simplest rudiments of education. His elder brother had received a lieutenancy in the army, and died in 1808, when Taylor was appointed to the vacant commission. In 1810 he was promoted to a captaincy; and in 1812, with 50 men, two-thirds of whom were ill of fever, he defended fort Harrison, on the Wabash, against a large force of Indians led by the famous chief Tecumseh. Promoted to the rank of maj. for his gallantry, he was employed during the war in fighting the Indian allies of Great Britain. In 1822 he built fort Jesup; in 1832 he served as col. in the Black Hawk war; and in 1836 was ordered to Florida, where he gained an important victory over the Seminole Indians at Okeechobee, for which he was appointed brig.gen., and made commander of the United States forces in Florida. In 1840, having been appointed to the command of the s.western department, he purchased an estate at Baton Rouge, Louisiana. On March 1, 1845, the U. S. congress passed the resolution for the annexation of Texas, formerly a province of Mexico, and for some time an independent republic. Texas claimed the Rio Grande for her s.western boundary; Mexico insisted that there could be no claim beyond the Nueces, and prepared to defend the disputed, if she could not reconquer the whole territory. Gen. Taylor was ordered to Corpus Christi, which point he occupied in Nov. with a force of 4,000. On Mar. 8, 1846, he moved toward the Rio Grande, across the disputed territory, and built fort Brown, opposite and commanding the Mexican port of Matamoras. Gen. Ampudia, the Mexican commander, demanded that he should retire

beyond the Nueces, pending negotiations; and on the refusal of gen. Taylor, his successor, gen. Arista, crossed the Rio Grande with a force of 6,000. On May 8, he was defeated at Palo Alto by gen. Taylor, with a force of 2,300; and a few days after, driven from a new position at Resaca de la Palma, across the Rio Grande. War was declared by congress to exist by the act of Mexico; 50,000 volunteers were called for, Taylor made maj. gen., re-enforced, and ordered to invade Mexico. On Sept. 9, with 6,625 men, he attacked Monterey, which was defended by about 10,000 regular troops. After 10 days' siege and 3 days' hard fighting, it capitulated. Gen. Scott having been ordered to advance on the city of Mexico by Vera Cruz, withdrew a portion of the troops of gen. Taylor, leaving him only 5,000 volunteers and 500 regulars, chiefly flying artillery, to meet an army of 21,000, commanded by president Santa Anna. He took a strong position at Buena Vista, fought a desperate battle, and won a decided victory. This victory, against enormous odds, created the utmost enthusiasm; and gen. Taylor, popularly called "old rough and ready," was nominated for president of the United States over Henry Clay, Daniel Webster, and gen. Scott; and this "ignorant frontier col., who had not voted for 40 years," and was a slaveholder, was triumphantly elected over gen. Cass, the democratic, and Martin Van Buren and Charles Francis Adams, free-soil candidates. Entering upon the presidency in 1850, he found a democratic majority in congress, with a small but vigorous free-soil party holding the balance of power, while the most exciting questions connected with the extension of slavery, as the admission of California, the settlement of the boundaries of Texas, the organization of the newly-acquired Mexican territories, etc., were agitating the country, and threatening a disruption, postponed by the compromises introduced by Mr. Clay. Worn down by the unaccustomed turmoil of politics, the rough, good-natured old soldier did not long enjoy his honors. On July 4, 1850, four months after his inauguration, he was attacked with bilious colic, and died on the 9th.

TAYLOR'S THEOREM, so called from its discoverer, Dr. Brook Taylor (q.v.), is a general method for the algebraic development of a function of a quantity, x , in powers of its increment h , and may be thus briefly explained and illustrated: Let $f(x+h)$ denote any function of $x+h$ (subject to the limitations below), then $f(x+h) = f(x) + f'(x)h + f''(x)\frac{h^2}{1.2} + f'''(x)\frac{h^3}{1.2.3} + \dots$, where $f(x)$ is the same function of x , as $f(x+h)$ is of $x+h$, and $f'(x)$, $f''(x)$, etc., are the first, second, etc., differential coefficients of $f(x)$. By a supplementary theorem, due to Lagrange, who was the first to appreciate to the full the value of Taylor's discovery, it was shown that the sum of all the terms of the series after n terms, could be represented by $f^n(x+th)\frac{h^n}{1.2\dots n}$, where t is some positive fraction less than unity. The theorem supposes that between certain limits, indicated by $h = 0$, and $h = \text{some finite quantity}$, neither $f(x)$ nor any of its derived functions vanish, or all of them do not become infinite; and the cases in which these conditions are not satisfied are often spoken of as instances of the "failure of Taylor's theorem." An important particular case of this theorem, known as *Maclaurin's*, or (more properly) *Stirling's Theorem*, was independently discovered; it is that case of the general theorem in which the various functions of x are made functions of zero, and is written $f(0+h) = f(0) + f'(0)h + f''(0)\frac{h^2}{1.2} + \dots$, etc. The best illustrations of these theorems are the binomial, exponential, logarithmic, and circular series; thus if the function be $(x+h)^n$, then $f(x) = x^n$, $f'(x) = nx^{n-1}$, $f''(x) = n(n-1)x^{n-2}$, etc.; and by substitution of these values we obtain Newton's *binomial* theorem; if the function be $a^x + h$, Taylor's series gives us as its equivalent $a^x(1+h \cdot \log. a + \frac{h^2}{1.2} \log. a)^2 + \dots$; and Maclaurin's gives $a^0 = 1 + h \cdot \log. a + \frac{h^2}{1.2} (\log. a)^2 + \dots$, which latter is the *exponential* theorem, and may be obtained from Taylor's series by division; if the function be $\log.(1+x+h)$, $\log. \frac{x+h}{x}$ being one of the cases in which Taylor's theorem fails), then Maclaurin's series gives the *logarithmic* theorem, $\log.(1+h) = h - \frac{h^2}{2} + \frac{h^3}{3} - \dots$, etc.; and the same theorem gives the various series expressing the values of $\sin. h$, $\cos. h$, $\sin. -h$, etc., etc. The history of this celebrated theorem is remarkable. On the first publication of the *Methodus Incrementorum*, it was entirely neglected by Leibnitz, who, in ignorance of its value, severely criticised the whole work; while the bitter hostility of John Bernoulli to British men of science, blinded him to the existence of any merit in any part of the work. The theorem never appeared in any of the works on the calculus published before D'Alembert's *Recherches*, and after that was given only in the French *Encyclopædia*; but neither D'Alembert nor Condorcet seems to have known that it was Taylor's, or to have fully appreciated its importance; and it was not till Lagrange, in the *Berlin Memoirs* for 1772, gave the name of its true author, and proposed to make it the foundation of the differential calculus, that it assumed that important position which it deserved to hold.

TAZEWELL, a co. in central Illinois, drained by the Mackinaw and Illinois rivers, the latter its n. boundary; traversed by the Chicago and Alton, the Toledo, Peoria and Warsaw, and the Indianapolis, Bloomington and Western railroads; about 550 sq.m.; pop. '80, 29,679—24,674 of American birth. The surface is in great part prairie land, and produces all the cereals in abundance. There are flour-mills, distilleries, and manufacturing of tools, carriages, and other articles. Co. seat, Pekin.

TAZEWELL, a co. in s.w. Virginia adjoining West Virginia; drained by the Clinch, Bluestone, and Holston rivers; 600 sq.m.; pop. '80, 12,861—12,839 of American birth, 1834 colored. The surface is crossed by the Clinch range of mountains and is rugged, though the valleys are productive; corn, oats, wheat, hay, wool, and dairy-products are the staples. There are several distilleries, tanneries, and cloth-dressing factories. Co. seat, Tazewell Court-House.

TAZEWELL, HENRY, 1753-90; b. Va.; after graduating from William and Mary college, studied law and practiced successfully in his native state. From 1775 to 1785 he was a member of the Virginia house of burgesses, and served on the committees which drew up the declaration of rights and state constitution. He was for many years a judge of the supreme court and court of appeals. In 1794 he was chosen U. S. senator, and in 1795 was president *pro tem.* of the senate.

TCHAD, or **TSAD**, **LAKE**, a large lake in Soudan, northern Africa, lat. 12° 30' to 14° 30' n., long. 13° to 15° 30' east. Its size varies with the time of year; it has an area of 10,000 sq.m. in the dry season, and is sometimes four or five times as large in the rainy months. According to Robb's it is 1150 ft. above sea-level. The shores are low, and for the most part unattractive; and a strip of swampy ground surrounds the fine open sheet of water which is the actual Tchad, and the margin of which is lined by papyrus and tall reeds, of from 10 to 14 ft. in height. Its depth in ordinary years is from 8 to 15 ft., but in some years the waters rise much higher; and of the islands, of which there are many densely peopled, only the more elevated afford shelter to the inhabitants. River horses and crocodiles swarm in the lake, and fish and water-fowl are abundant. The banks are infested by a tribe called the Budduma or Jedina, who live by piracy. The inhabitants are black or dark-brown, have regular features, and are decently clothed. From the w. the large river Yaobe enters the lake; and from the s. the Shari, which in its lower course is upward of 1800 ft. broad, and has a large western affluent, the Ba Logon. Lake Tchad, whose waters are perfectly fresh, has no regular outlet. But Dr. Nachtigal has proved that it sometimes overflows toward a great depressed plain lying 300 m. to the n. east.

TCHERKA'SI, a t. of Russia, in the government of Kiev, 100 m. s.e. of the town of Kiev, on the Dnieper. Pop. '67, 14,433.

TCHERKASK, **STAROI** (Old Tcherkask), a t. of s. Russia, formerly the capital of the country of the Cossacks of the Don, stands on the right bank of the Don, 13 m. s. of New Tcherkask (see NOVOTCHERKASK), the present capital. Pop. 15,000.

TCHERNIGOV, a government in s.w. Russia, drained by the Dnieper and the Desna rivers; about 20,000 sq.m.; pop. 70, 1,659,600. The surface is generally level. The soil is extremely rich. The principal productions are brandy, honey, and cattle. The horses raised here have a high reputation. Capital, Tchernigov.

TCHUKTCHIES, a wandering tribe in Siberia, supposed to be kin to the Koriaks, living near Behrings strait. They closely resemble the Indians of the adjacent continent. The greater part of them wander from spot to spot with herds of reindeer, while some bands live on the coast and support themselves by seal and walrus hunting. Their number is unknown, and estimates vary greatly. The name Tchukthches is also given to an Alaska tribe of Koniagas, living on Bristol bay, and noted for their ingenious carving.

TEA, *Thea*, a genus of shrubs of the natural order *ternstramiacea*, very nearly to the genus *camellia* (q.v.), and distinguished from it only by the not deciduous calyx, and by the dissepiments remaining connected in the center of the capsule after it opens. The genus seems to derive its importance entirely from a single species, the dried leaves of which are the tea of commerce, one of the most important articles of commerce in the world, and yielding the most esteemed and extensively used of all non-alcoholic beverages. This species, the tea shrub or CHINESE TEA (*T. sinensis*), is 20 to 30 ft. high, but in a state of cultivation only 5 to 6 ft. high, with numerous branches and lanceolate leaves, which are 2 to 6 in. long. The flowers grow singly or two or three together in the axils of the leaves; they are rather large, white, and fragrant, with 5-parted calyx, 6 to 9 petals, and many stamens. By cultivation for many centuries, numerous varieties of this plant have been produced in China, some of which have been reckoned as distinct species, particularly *T. viridis*, formerly supposed to yield green tea, *T. Bohea*, formerly supposed to yield black tea, and *T. striata*. Of these, the first-named has the longest, and the last has the shortest leaves. The Assam tea, which has been called *T. Assamensis*, appears also to be a mere variety of the same species.

The cultivation of tea in China is chiefly confined to the regions between n. lat. 24° to 35° and e. long. 115° to 122°. Tea for domestic use is, however, cultivated both in more southern and more northern regions. The plant is to be accounted subtropical, but bears a tropical climate well, and can also accommodate itself to cold winters. In the neighborhood of London it often endures all the frost of winter without protection. In few of the countries into which it has been introduced, however, is the flavor of the dried leaf such as it is in China. The use of tea is said to have been introduced into China itself from the Corea about the 4th c. of the Christian era, and to have extended to Japan about the 9th century. The Chinese cultivate it chiefly on the southern slopes of hills. A new plantation is made by sowing the seed in holes at proper distances, two or three seeds being put into a hole to secure a plant. The first crop is obtained in the third year, when the shrub is by no means full-grown. When about seven years old, it yields only a scanty crop of hard leaves, and is cut down, when new shoots rise from the root, and bear fine leaves in abundance. This is repeated from time to time, till the plant dies at about the age of thirty years.

History and Commerce.—All that can be affirmed regarding the early history of this beverage is, that it appears to have been used for ages in China, where it is believed by the natives to be indigenous. It first became known to Europeans at the end of the 16th c., though it is only mentioned by the Portuguese writer Maffei in his *Historiæ Indicæ*, who refers to it as a product both of China and Japan. The first reference to it by a native of Britain is in a letter dated June 27, 1615, written by a Mr. Wickham, which is in the records of the East India company; and it is curious to observe that both the Portuguese and English writers referred to use their own rendering of the native name, which is *tscha*. Maffei calls it *chia*, and Mr. Wickham, *chac*. From this time, it became gradually known to the wealthy inhabitants of London, in the form of occasional presents of small quantities from India, obtained from China, or by small lots in the markets from time to time, but always exorbitantly dear, fetching sometimes as much as £10 the lb., and never less than £5. A rather large consignment was, however, received in 1657; this fell into the hands of a thriving London merchant, Mr. Thomas Garraway, who established a house for selling the prepared beverage; and that house, under the name of "Garraway's coffee-house," is still a famous establishment in that city. From 1660 until 1689, a duty was levied on the drink made with tea at the rate of 8d. per gallon; but from the latter date a duty of 5s. per lb., with an addition of 5 per cent *ad valorem*, was levied. For many years, the duties, although occasionally changed, were always very high, and were levied by both the customs and the excise. The expiration in 1683 of the charter of the East India company, which had held a complete monopoly of the tea-trade, produced a change; the *ad valorem* duty was abolished, and differential duties of 1s. 6d., 2s. 2d., and 3s. per lb. were substituted; but they worked badly, and were abandoned in 1833 for one uniform rate of 2s. 1d. per lb., to which, in 1840, was added an additional 5 per cent. From that time to the present, several changes, always reductions, have taken place, until now, when the duty is only 6d. per lb. The import for the year 1875 was nearly 200,000,000 lbs., value about £14,167,000; the import for 1876 was 185,698,190 lbs., value £12,812,832; for 1877, 187,515,284 lbs., value £12,480,740.

Much mystery and error for a long time existed upon the subject of the species producing the tea of commerce. By many it was said that the qualities known as black teas were produced by the species known to botanists as *T. Bohea*, and the green teas from *T. viridis*. Others held that only one species was used to make both the black and green varieties, and that the difference arose from the method and time of preparation. The eminent botanical traveler, Mr. Robert Fortune, has, however, entirely set the question at rest by investigating the matter on the spot. He found that in the Canton district, where black teas alone are prepared, only the *T. Bohea* is grown; while in the province of Che-kiang only *T. viridis* is grown, and green teas made. But the cultivation of the latter plant he also found to be absolutely universal in the Fokien district, although the inhabitants make only black teas. The tea-farms are mostly in the n. of China, and are usually of small size, and require much attention: for the plant will only thrive in well manured or very rich soil, and the spaces between the plants, which are 4 ft. apart, must be kept in good order, and free from weeds. The farms always occupy the hill-sides, where the soil is deep and well drained. Although an evergreen, the leaves can only be gathered at certain seasons: the first is in April, when the new leaves begin to burst from the buds; and some of these in their most tender state are gathered and made into young hyson of the finest quality; so fine, indeed that it has rarely been brought to England, because it is said to lose flavor by the sea-voyage. Much is, however, sent overland to Russia, where it fetches an exorbitant price. The ordinary picking begins just after the summer rains are over, at the beginning of May; and later in the season, a third picking takes place, the produce of which is inferior, and used only by the poorer classes of the country. The later gatherings are more bitter and woody than the earlier, and yield less soluble matter to water. The leaves, when freshly plucked, possess nothing of the odor or flavor of the dried leaves, these properties being developed by the roasting which the leaves undergo in the process of drying. Moreover, different qualities of tea are prepared from the same leaves, which may be made to yield green or black teas at will.

For a description of the specific processes for obtaining the green and the black teas generally, we refer to Mr. Fortune's work (*Tea Countries of China*), or to Johnson's *Chemistry of Common Life*, vol. i, p. 161, in which it is quoted. It is sufficient here to remark, *first*, that, in the process of drying, the leaves are roasted and scorched in such a way as necessarily to induce many chemical changes in them; the result of such changes being to produce the varieties of flavor, odor, and taste by which the different kinds of teas are distinguished; and *secondly*, that the different colors of green and black teas are due to the mode in which the leaves are treated. For *green teas* the leaves are roasted in pans almost immediately after they are gathered. After about five minutes' roasting, during which they make a crackling noise, become moist and flaccid, and give out a good deal of vapor, they are placed on the rolling-table, and rolled with the hands. They are then returned to the pans, and kept in motion by the hands: in about an hour, or rather more, they are well dried, and their color, which is a dull green, but becomes brighter afterward, has become *fixed*. The essential part of the whole operation is now over, nothing more being required than to sift and re-fire it. For *black teas*, the leaves are allowed to be spread out in the air for some time after they are gathered; they are then further tossed about till they become flaccid; they are next roasted for a few minutes, and rolled, after which they are exposed to the air for a few hours in a soft and moist state; and lastly they are dried slowly over charcoal fires, till the black color is fairly brought out. Hence the dark color and distinguishing flavor of black teas seem due to the long exposure to the atmosphere in the process of drying, and the oxygen of the air acting rapidly upon the juices of the leaf, and especially upon the astringent principle during this exposure. For the purpose of giving special scents to different varieties of tea, numerous odoriferous plants are employed in different parts of China; the cowslip-colored blossoms of the sweet-scented olive (*olea fragrans*) communicate an especially fragrant scent to tea.

The adulteration of tea, when the duty was very high, was probably carried on to a great extent; but notwithstanding the terrible tales of alarmists, it may be asserted that very little adulteration of tea is now carried on in Great Britain. In China, spurious teas have been prepared and sent to this country under the name of "lie teas," but they had no sale, and of course were discontinued. The Chinese give an artificial coloring to the green teas sent to Europe because it pleases the eye, but the coloring matter is very innocuous, and is never produced by heating over copper plates—a popular error, which has been persisted in for a long time without a shadow of truth for its foundation. Prussian blue in very minute proportion, and a species of native indigo and gypsum, are the real materials employed for giving the face, as it is called.

In 1836 the culture of tea was attempted on a large scale in India, under the direction of the able and indefatigable botanists, Dr. Royle and Dr. Falconer; and after some difficulty, a good supply of plants was introduced to the districts of Kumaon and Gurhwal, and in the mean time plantations formed at an earlier period in Assam were making great progress. From these sources a steadily increasing supply is received, the value of which in 1876 was £2,473,882. The quality, too, is superior to many of the Chinese teas, a fact which is testified by the large quantity of Indian teas now used. The only other country which has grown tea successfully is Brazil, where, in the high lands, tea of the most excellent quality is produced, and in sufficient quantities to supply a large portion of the Brazilian demand.

The varieties of tea are very numerous; the following are those found in the shops of Great Britain:

GREEN TEAS.—*Chinese*: (1). Gunpowder sorts—viz., Shanghae, Ping-suey or pin'-head, Moyune, imperial Moyune, and Canton; (2). Hyson sorts—viz., Shanghae, Shanghae young, Moyune, Moyune young, Canton young, and Twankay or imperial Hyson. *Japanese*: Gunpowder and young Hyson. *Java*: Gunpowder.

BLACK TEAS.—*Chinese*: (1). Congo sorts—viz., Canton, Foo-chow-foo, Hung-muey, Oopack, Kaison, and Oonam; (2) Pekoe sorts—viz., plain orange, Foo-chow, scented orange, Canton scented orange, and flowery Pekoe, Oolong, and Souchong. *Assam*: Congo, orange Pekoe, and Souchong. *Java*: Congo and imperial. The latter is made up into little balls about the size of a pea, and is rare.

The use of the infusion of the leaves of tea as a beverage is general in the s.e. parts of Asia, and has become prevalent also amongst the British—at home and in all their colonies—the Americans, and the Dutch. In Scandinavia, tea is also much used by all who can afford it. In other parts of Europe the use of tea is much less general, and is chiefly confined to maritime districts, towns, and the wealthy. The importation of tea overland through Russia is inconsiderable, and the sea trade is chiefly to Britain and North America.

The *substitutes* for tea, in countries where it is difficult to obtain it, are of two sorts: those which contain theine, and which consequently have the same stimulating effect; and those which are destitute of that principle, and only resemble the true tea in flavor or smell, or which possess some other stimulating principle. Of the former class are—(1). Maté (q.v.); (2). Guarana (q.v.)—so rich is this material in theine that it has lately been used in this country for obtaining that principle; and it has been introduced into Austria and France as a powerful medicine; (3). Coffee-leaves, which are occasionally prepared as a substitute in the West Indies; they would be more gener-

ally used were it not for the disagreeable smell of the infusion; (4). the kola-nut, the active principle of which was some years ago ascertained to be theine.*

The second class, or those which do not possess that principal, are very numerous; but only a few can be said to be of any importance from being in general use in the countries producing them. These are the Siberian tea—leaves of *saxifraga crassifolia*; the Appalachian tea—leaves of *prinos glabra*; the Labrador tea—leaves of *ledum buxifolium*; the Chilian tea—leaves of *Eugenia ugni*; Trinidad pimento tea—leaves of *Eugenia pimenta*; and the leaves of the partridge-berry, which are used in some parts of North America. The Fahani tea of Mauritius, and a great many more, should be regarded in the light of medicines rather than as ordinary beverages, although they are generally classed as substitutes for ordinary tea.

Tea, in its chemical, physiological, and medicinal relations.—On submitting the ordinary commercial tea to analysis, we find that it contains (1) a volatile or essential oil; (2) theine or caffeine, described in this work under the latter name; (3) a nitrogenous compound analogous to caseine or gluten; (4) a modification of tannin; besides gum, sugar, starch, fat, woody fiber, salts, etc. The volatile oil gives to tea its peculiar aroma and flavor. The proportion in which it exists is, according to Miller, about 0.79 per cent in green, and 0.6 per cent in black tea. It may be obtained by distilling the tea with water, and is found to exert a most powerfully stimulating and intoxicating effect. In China tea is seldom used until it is a year old, on account of the well-known intoxicating effects of new tea, due probably to the larger proportion of essential oil which it usually contains. The headache and giddiness of which tea-tasters complain, and the attacks of paralysis to which, after a few years, persons employed in packing tea are found to be liable, are due to the action of this oil, which according to Johnston, "does not exist in the natural leaf, but is produced during the process of drying and roasting."

Chemistry of Common Life, 1855, vol. i. p. 170.

The theine or caffeine, an alkaloid of weak basic properties, varies considerably in different kinds of tea. Peligot found it to range from 2.2 to 4.1 per cent in ordinary green teas, while very rarely it amounted to 6 per cent; whereas from the researches of Stenhouse it appears that not more than 2 per cent is usually contained in the ordinary teas in the English market. It may readily be obtained by the following simple experiment. When dry finely-powdered tea leaves, or a dried watery extract of the leaves, are put on a watch-glass covered with a paper cone, and the whole is placed upon a hot plate, or exposed to the heat of a spirit-lamp, a white vapor gradually rises and condenses on the interior of the cone, in the form of small crystals, which consist of theine. As it has no odor, and only a slightly bitter taste, it obviously has little to do with the taste or flavor of the tea from which it is extracted; it is, however, to the presence of this ingredient that the peculiar physiological action of tea on the animal economy is due. This substance is represented by the formula $C_8H_{10}N_4O_4 + 2Aq$, and is remarkable for the large quantity of nitrogen (28.83 per cent) which it contains, and which is nearly

*Dr. Daniell's observations on the kola-nut (see the article COLA-NUT) are of such importance as to demand a notice here. From time immemorial the seeds of the kola-nut have been held in inestimable value as a luxury by the inhabitants of the vast tract between the west coast and the region of Central Africa known as Sudan; and the trade in these nuts has extended to various markets on the Mediterranean. The Portuguese, Dutch, and subsequently the English voyagers, fell into the negro predilections for this fruit; and eventually the due gratification of this want became a matter of imperative necessity. Dr. Daniell's knowledge of the tonic and astringent properties of these nuts was gained during his residence on the Gold Coast, where the white inhabitants were in the habit of taking a decoction of the fresh nuts, with apparent benefit, in a particular form of endemic diarrhæa, arising more from local relaxation of the mucous membranes than from constitutional debility. On taking the medicine late, two evenings in succession, when he was afterward suffering from an attack of this kind in Jamaica, he found that he was deprived of sleep during the remainder of the night. On intermitting the decoction, the natural rest returned, and on returning to it, the insomnia again occurred. Hence he was led to suspect that a substance analogous to theine must be present; and a chemical analysis of the nuts yielded crystals in all respects resembling those of theine, and subsequently proved by the more careful investigations of Dr. Atfield to be composed of that alkaloid. Wherever the slave-trade prevailed, the tree yielding the kola-nut (*cola acuminata* of Robert Brown) followed as a matter of necessity, being imported and cultivated for the benefit of the negro. It was thus introduced into the Mauritius, Jamaica, and other West India islands, Brazil, Mexico, etc. It was specially intended to act in warding off the predisposition to epidemic outbreaks of suicidal mania, which not unfrequently almost depopulated considerable districts. While Dr. Daniell's experiments disprove the statement (alluded to in the article COLA-NUT) that these seeds render bad water palatable, his investigations, confirmed as they are by Dr. Atfield's chemical analysis, show that whatever may be their food-value (which Dr. Daniell estimates higher, from his observations, than Dr. Atfield from their analysis), they may be advantageously substituted for coffee. See the papers by Dr. Daniell, "On the Kola-nut of Tropical West Africa," and by Dr. Atfield, "On the Food-value of the Kola-nut," in the *Pharmaceutical Journal* for March, 1855.

†The following comparative analysis of tea, coffee, and the dry kola-nut, are interesting, as showing in how nearly they contain the same organic constituents, although in different proportions:

100 Parts of tea contain	100 Parts of Coffee contain	100 Parts of Kola- nuts contain
Water..... 5	12	13.65
Theine..... 3	1.75	2.13
Caseine..... 15	13	6.33

Sugar..... 3	6.5	
Starch..... a trace	a trace	42.00
Tannin..... 36.25	4	..
Aromatic oil..... 0.73	0.002	1.52
Fat..... 4	12	
Fiber..... 20	35	20.00
Mineral substances..... 5	6.7	3.20

double the amount contained in albumen, fibrine, etc. It is also remarkable as occurring in plants very unlike each other, and growing in remote countries, which have by instinct been selected by different nations for the purpose of yielding a slightly exciting and very refreshing beverage (see above). From numerous experiments, it appears that the introduction into the stomach of a small quantity of theine (such as three or four grains, which is the quantity contained in about one-third of an ounce of good tea) has the remarkable effect of diminishing the daily waste or disintegration of the bodily tissues, which may be measured by the amount of solid constituents contained in the urinary secretion. And if the waste be lessened, the necessity for food to repair that waste will obviously be diminished in an equal proportion. "In other words," says Professor Johnston, "by the consumption of a certain quantity of tea, the health and strength of the body will be maintained in an equal degree upon a smaller supply of ordinary food. Tea, therefore, saves food—stands to a certain extent in the place of food—while at the same time it soothes the body, and enlivens the mind."—*Op. cit.* p. 173. It should, however, be stated, that the generally accepted view, that theine checks the destruction of the tissues, has been recently called in question by an excellent experimental observer, Dr. Edward Smith, in various memoirs published in the *Philosophical Transactions* and elsewhere. If double the above quantity of theine (or of the tea containing it) be taken, there is a general excitement of the circulation, the heart beating more strongly, and the pulse becoming more rapid; tremblings also come on, and there is a constant desire to relieve the bladder. At the same time the imagination is excited, the mind begins to wander, visions appear, and a peculiar kind of intoxication comes on; the symptoms finally terminating, after a prolonged vigil in a sleep arising from exhaustion. It is not definitely known what changes theine undergoes in the animal economy, but when oxidized artificially it becomes decomposed into methylaniline or methyllia (C_6H_5, H_2N), hydrocyanic acid (C_2N), and amalic acid ($C_{12}H_7N_2O_5$). The nitrogenous compound allied caseine or gluten constitutes about 15 per cent of the weight of the leaf. As hot water extracts very little of this substance, a large quantity of this nutritious matter, which forms about 28 per cent of the dried spent leaves is thrown away. Much of it might be dissolved if a little carbonate of soda were added to the boiling water with which the tea is made; and in the brick-tea (the refuse and decayed leaves and twigs, pressed into molds) used by the Tartars, most of this substance is utilized. They reduce the tea to powder, and boil it with the alkaline water of the steppes to which salt and fat have been added, and of this decoction they drink from 20 to 40 cups a day, mixing it first with milk, butter, and a little roasted meal. But without the meal mixed only with a little milk, they can subsist for weeks on this thin fluid food. To the astringent principle or tannin, which forms from 13 to 18 per cent of the dried leaf, tea owes its astringent taste, its constipating effect upon the bowels, and its property of communicating an ink-like color to water containing salts of iron. Whether this ingredient contributes in any degree to the exhilarating, satisfying, or narcotic action of tea, is not known. Professor Johnston thinks it probable that it does exert an exhilarating effect, from the fact, that a species of tannin is the principal ingredient of the Indian betel-nut, which, when chewed, produces a mild and agreeable form of intoxication.

It is usual to judge of the quality of a tea by its aroma, and by the flavor and color of the infusion which it yields; but to these tests should be added the determination of the amount of soluble matter which it readily yields to boiling water. It is stated by Miller that our ordinary tea contains about 45 per cent of soluble matter; but the independent researches of Davy and Peligot show that boiling water seldom extracts more than one-third of the weight of the dry tea; while in J. Lehmann's experiments, only one-sixth (15.5 per cent) was extracted. Good tea should, moreover, not yield more than 5 or 6 per cent of ash when incinerated; and a portion of this is probably due to the coloring matter which the Chinese add to the green teas prepared for the foreign market. For this purpose they used to employ a mixture of Prussian blue and gypsum, but indigo is now commonly used, which is probably harmless. Drinkers of green tea who wish to know which of these adulterations they are swallowing, may easily determine the point by the following simple experiment: "If a portion of the tea be shaken with cold water and thrown upon a bit of thin muslin, the fine coloring matter will pass through the muslin and settle to the bottom of the water. When the water is poured off, the blue matter may be treated with chlorine, or a solution of chloride of lime. If it is bleached, it is indigo; if potash makes it brown, and afterward a few drops of sulphuric acid make it blue again, it is Prussian blue."—Johnston, *op. cit.*, p. 181, note.

Much has been written regarding the dietetic and medical uses of tea. While some physicians have over-praised its value, others have regarded it as the source of numerous diseases, especially of the nervous system. In his admirable work on *Hygiene*, Dr. Parkes remarks that "tea seems to have a decidedly stimulative and restorative action on the nervous system, which is perhaps aided by the warmth of the infusion. No depression follows this. The pulse is a little quickened. The amount of pulmonary carbonic acid is, according to Dr. E. Smith, increased. The action of the skin is increased; that of the bowels lessened. The kidney excretion is little affected; perhaps the urea is a little lessened, but this is uncertain, the evidence with regard to the urine being very contradictory." Dr. E. Smith considers that "tea promotes all vital actions." Dr. Parkes regards it as a most useful article of diet for soldiers, and it is well known that cold tea is frequently preferred to beer or cider by sportsmen, reapers, and others

engaged in laborious work in hot weather. As a general rule, tea is very prejudicial to young children, and is not a suitable drink till growth is completed; and adults of an irritable constitution, or a leuco-phlegmatic temperament, often suffer from its use. Those with whom tea does not agree will generally find cocoa the best substitute. Old and infirm persons usually derive more benefit and personal comfort from tea than from any other corresponding beverage. In fevers, tea, in the form of a cold weak infusion, is often of great service. In persons of a gouty and rheumatic tendency, and especially in such as are of the *lithic acid diathesis* (q.v.), weak tea, taken without sugar, and with very little milk, is the best form of ordinary drink. In some forms of diseased heart, tea proves a useful sedative, while in other cases it is positively injurious; and a cup of strong green tea, especially if taken without sugar or milk, will often remove a severe nervous headache. It is nearly as powerful an antidote in cases of opium-poisoning as coffee; and very strong tea has been the means of preserving life, in cases of poisoning by tartar-emetic, the tannin being in these cases the active agent. It is impossible to speak too strongly against the habit occasionally adopted by students of keeping off their natural sleep by the frequent use of strong tea. The persistent adoption of such a habit is certain to lead to the utter destruction of both bodily and mental vigor.

TEA (*ante*). The American tea-trade began in 1784, when the first American ship sailed for China. This enterprise was followed in the next year by the dispatching of two vessels, resulting in an importation, direct, of 880,000 lbs.; and in 1786 five vessels brought more than a million pounds. The first direct importation of Japan tea was made in 1868 from Yokohama to San Francisco. The intervention of steam in the tea-carrying trade occurred first in 1867, when the Pacific mail steamer *Colorado* made a voyage to Hong Kong and Yokohama, and brought back tea to San Francisco. The time now occupied in the transportation of tea from Japan to New York is 30 to 40 days; and from Shanghai to the same port, 40 to 50 days, via San Francisco and the Pacific railroad. During the war of the rebellion there was levied a war-duty of 25 cents per lb. on tea; which was reduced to 15 cents in 1871, and entirely removed in the following year. The following table gives the quantity and value of the tea imported into the United States for the fiscal years ending June 30, 1858-79 inclusive:

YEAR.	POUNDS.	DOLLARS.	YEAR.	POUNDS.	DOLLARS.
1858.....	32,995,021	7,361,815	1869.....	43,754,351	13,687,750
1859.....	29,268,757	7,388,741	1870.....	47,408,481	13,862,272
1860.....	31,696,657	8,915,327	1871.....	51,364,919	17,251,617
1861.....	26,117,956	6,977,283	1872.....	63,811,003	22,913,575
1862.....	24,838,421	6,545,664	1873.....	61,815,126	21,363,170
1863.....	29,761,037	8,013,772	1874.....	55,811,605	21,112,324
1864.....	37,329,176	10,549,880	1875.....	61,856,860	22,673,793
1865.....	19,568,818	4,956,730	1876.....	62,887,153	19,524,166
1866.....	42,092,738	11,123,231	1877.....	58,247,112	16,181,467
1867.....	39,492,658	12,415,037	1878.....	65,366,704	15,660,168
1868.....	37,843,612	11,111,560	1879.....	60,191,673	14,557,618

TEAK, the name of two kinds of timber, valuable for ship-building and other purposes, one of which is known as INDIAN TEAK, and the other as AFRICAN TEAK. The trees which produce them belong to very different orders. INDIAN TEAK (*tectona grandis*) is a tree of the natural order *verbenaceæ*. It is found in the mountainous parts of Malabar, and elsewhere in Hindustan, and in the Eastern Peninsula, Ceylon, Java, etc. It has been introduced in some parts of India, in which it is not indigenous. Dr. Roxburgh introduced it in the low grounds of the Circars as early as 1790. It has been planted in some parts of Ceylon, but not yet with much result, as it takes 60 or 80 years to grow to a large size. It is a beautiful tree, attaining a height sometimes even of 200 ft., and rising above all the other trees of the East Indian forests. It has deciduous oval leaves of 12-24 in. long, covered with rough points; great panicles of white flowers, with 5-6 cleft corolla, and 4-celled drupes about the size of a hazel-nut. Its flowers are used medicinally in cases of retention of urine, and its leaves by the Malays in cholera. Silk and cotton stuffs are dyed purple by the leaves. The timber is the most valuable produced in the East Indies; it is light and easily worked, strong, durable, and not liable to the attacks of insects. It abounds in silex, and resembles coarse mahogany. It is extensively used for ship-building, for which purpose it is imported into Britain. All the finest ships built in India, and many built in England, are of teak. The most extensive teak forests are in Pegu. The teak generally rather grows in clumps in forests than forms forests of itself.—AFRICAN TEAK, sometimes called AFRICAN OAK, is a timber similar to East Indian teak. It is now believed to be the produce of *Olifieldia Africana* a tree of the natural order *Euphorbiaceæ*; but the leaves of many different trees have been brought to botanists as those of the African teak.

TEAL, *Querquedula*, a genus of ducks (*anatidæ*) with very slightly lobed hind-toe, narrow bill, as long as the head, the sides nearly parallel, or widening a little at the end, the wings pointed, the tail moderately large, and wedge-shaped. Some naturalists divide the genus into two—*nettion*, in which the bill has parallel sides, and a small nail at the tip; and *querquedula*, in which it is widened, and has a larger nail. The species are numerous, the smallest of the ducks, and widely distributed over the world. They

generally frequent rivers and lakes, feeding principally at night on aquatic insects, worms, mollusks, seeds, etc. The COMMON TEAL (*Q. or N. crecca*) is plentiful in Britain and in most parts of Europe. It is occasionally but rarely seen in North America. Its whole length is about 14 inches. It is a very beautiful bird; the head of the male brownish-red, the body transversely undulated with dusky lines, a white line above, and another beneath the eye, the speculum black and green. It makes its nest on the margins of lakes or rivers, of decayed vegetable matter lined with down, and lays eight or ten eggs. Its flesh is extremely delicate. It was domesticated by the ancient Romans, and seems capable of being advantageously introduced into our poultry yards.—The GARGANEY (q.v.) is another British species.—The GREEN-WINGED TEAL (*Q. or N. Carolinensis*) of North America is very similar to the common teal, but it is at once distinguished by a white crescent in front of the bend of the wings. It is occasionally seen in Europe. In its summer migrations, it visits very northern regions.—The BLUE-WINGED TEAL (*Q. discors*) is very abundant in many parts of North America. It is rather larger than the common teal. It is easily domesticated.

TEANO, a city of Terra di Lavoro, a province of the Sicilies, corresponding to the ancient Teanum. The town lies on the s. slope of the Rocca Monfina, a range of volcanic character; pop. about 13,000. The place is the seat of a bishopric and is interesting from the ruins of an ancient theater and amphitheater, Roman inscriptions, and a castle and cathedral dating from the 15th century.

TEAR PITS. See DEER.

TEARS. See LACHRYMAL ORGANS, *ante*.

TEASEL, *Dipsacus*, a genus of plants of the natural order *Dipsacæ* or *Dipsacaceæ*. This order consists of herbaceous and half-shrubby exogenous plants, with opposite or whorled leaves, and flowers in heads or whorls, surrounded by a many-leaved involucre. About 150 species are known, natives of the temperate parts of the Old World. In the genus *Dipsacus*, the flowers are separated from each other by long, stiff, prickly-pointed bracts. The only valuable species of the order is the FULLER'S TEASEL, or CLOTHIER'S TEASEL (*D. fullonum*), a native of the s. of Europe, naturalized in some parts of England. It is a biennial, several feet high, with sessile serrated leaves, the stem and leaves prickly; and with cylindrical heads of pale or white flowers, between which are oblong, acuminate, rigid bracts, hooked at the point. The heads are cut off when the plant is in flower, and are used in woolen factories, and by fullers and stockingmakers, for raising the nap on cloth. No mechanical contrivance has yet been found to equal teasel for this purpose; to which the hooked points, the rigidity, and the elasticity of the bracts are admirably adapted. The heads of teasel are fixed on the circumference of a wheel or cylinder, which is made to revolve against the surface of the cloth. Teasel is cultivated in many parts of Europe, and is imported into Britain from Holland and France. It is cultivated to some extent in England, particularly in Somersetshire and Yorkshire. The seed is sown in March, on well-prepared strong rich land, and the plants thinned out to a foot apart. In August of the second year, the heads are ready to be cut. They are packed in bundles of 25 each, and about 160 such bundles are the usual produce of an acre. The flowers of teasel abound in honey, and the seeds are used for feeding poultry. The root was formerly in use as a diuretic and sudorific.

TEBESSA, a t. in Algeria, province of Constantine; 75 m. s.e. of Constantine. It is entered by two gates, one of which is probably of Roman construction, and in the form of a triumphal arch. The leading buildings are Roman, of which a fortress is still well preserved; a small temple also remains unimpaired, which is now used for soap works. It has an extensive trade in boots, shoes, dates, and hardware.

TECHE, Bayou, in Louisiana, begins in St. Landry's parish, and after a s.e. course of about 175 m. empties into Atchafalaya bayou. It is navigable for small steamboats as far as St. Martinsville.

TECHNICAL EDUCATION (Gr. *techné*, art) means special instruction and training for the industrial arts. This subject has received much attention of late years in consequence of comparisons drawn between the manufactures of Great Britain and those of other countries shown in the great international exhibitions held in London, Paris, Vienna, and Philadelphia. Some good judges have asserted that owing to the superior training given in continental schools to young persons in the sciences specially bearing on the arts and manufactures, our neighbors are making much more rapid progress than we are. At all events, so much attention is now given to this kind of instruction abroad, that we can no longer afford to run the risk of falling behind in so important a matter. The subject was taken up by the society of arts in London in 1853, a committee of which body reported, after due inquiry, that the want of the technical element was a serious defect in the education of the country. In 1868 a select committee of the house of commons (Mr. Samuelson's) took much evidence, and made a report on this subject recommending that the state aid given to the teaching of science as applied to industry should be increased. Another parliamentary inquiry in the form of a royal commission on the advancement of science took place in 1870, 1871, and 1872, at which a great mass of evidence was given by most of the prominent men of science in the country, and the commission has made several reports on the subject. This inquiry was not specially directed to what we may call the practical sciences, nevertheless much of the evidence bore upon these.

Government aid for the teaching of science to the industrial classes is now given through the science and art department of the committee of council on education, which, in 1859, established a system by which payments on results are given to certified teachers, and prizes to successful pupils. The examination questions are framed by a staff of eminent scientific men, and examinations are held all over the country in May. For a number of years past the subjects have been as follow, with exception of No. 24, which has been recently added: 1, practical plane and solid geometry; 2, machine construction and drawing; 3, building construction; 4, naval architecture and drawing; 5, pure mathematics; 6, theoretical mechanics; 7, applied mechanics; 8, acoustics, light, and heat; 9, magnetism and electricity; 10, inorganic chemistry; 11, organic chemistry; 12, geology; 13, mineralogy; 14, animal physiology; 15, elementary botany; 16 and 17, biology, including animal and vegetable morphology and physiology; 18, principles of mining; 19, metallurgy; 20, navigation; 21, nautical astronomy; 22, steam; 23, physical geography; 24, principles of agriculture. Since 1878 a new subject called physiography has taken the place of physical geography.

The success of this scheme is shown by the great increase (seen in the following table) which has taken place in the number of schools, and pupils that avail themselves of it:

	No. of Schools.	No. of Students.
1860.....	9	500
1866.....	153	6,835
1873.....	1,182	48,546
1876.....	1,484	52,330

The parliamentary grant for payment to teachers on results as respects science, to which the above table alone refers, was in the financial year 1876-77 £50,000, besides a sum of £3,500 for prizes to students, and a further sum of £2,500 for examples, books, materials, etc. About an equal sum was voted for the encouragement of art (chiefly free-hand drawing) in night schools for artisans, and in public elementary schools.

Besides the government scheme of science instruction for artisans, there are a number of private or semi-private institutions where prelections of a technological nature are given. Among the most successful of the older ones are the Watt institution (school of arts) at Edinburgh, and the Andersonian university at Glasgow. The former was established in 1821, and for more than 30 years the principal subjects taught were mathematics, natural philosophy, chemistry, and mechanical drawing. Within the last 20 years other subjects have been added, and the total number of students is now between 1000 and 1500 annually. The evening courses of the Andersonian university, where much the same subjects are taught, are likewise very largely attended by artisans. Colleges for teaching science with special reference to the useful arts, but science of a more advanced character than can easily be taught during evening hours only, have been quite recently established in several localities, such as that of Newcastle, in connection with the university of Durham, the Yorkshire college of science at Leeds, and the college founded and endowed by sir Josiah Mason at Birmingham. Of a high character also is the instruction given in the royal school of mines, London, established in 1851, and the royal college of science in Dublin, both government institutions. The naval and military colleges are essentially of a like nature. At Cirencester there is a fully equipped agricultural college established about 30 years ago. Several of the London corporations are now about to provide technical instruction.

Technical schools have existed for a long time on the continent. Of the more recently organized ones those of Zurich and Carlsruhe are the most extensive. The former is a college and polytechnic school combined, having about 500 students and a large staff of professors. At Carlsruhe, which is simply a polytechnic school, there are 600 students and 40 professors and lecturers. Several polytechnic schools of a high class exist in France, and some have lately been founded in the United States.

The journal of the society of arts, the reports of the science and art department, and the reports of select committee and the royal commission above referred to, contain much interesting information on this subject.

TECHNOLOGY (Gr. *techné*, art) is the name given to the science or systematic knowledge of the industrial arts. In its widest sense, it would embrace the whole field of industry, but it is restricted in usage to the more important manufactures (spinning, weaving, metallurgy, brewing, etc.). Technology is not an independent science, having a set of doctrines of its own, but consists of applications of the principles established in the various physical sciences (chemistry, mechanics, mineralogy, etc.) to manufacturing processes. A complete course of instruction in technology could only be of the most superficial kind. The essential preparation for any branch of the manufacturing arts is the study of the fundamental physical sciences which are taught in schools and universities; and the special applications to the branch which the student has to pursue professionally can best be learned from special treatises on the subject in connection with practice in a manufacturing establishment. A general knowledge, however, of the arts of manufacture is interesting and instructive to all, and hence the museums of industry recently established by the British government, and yet in their infancy, promise to be of great benefit to the public in general, as well as to the manufacturer. See **TECHNICAL EDUCATION**.

TECK, a duchy situated in Swabia during the middle ages. It derived its name from the castle of Teck, the ruins of which are still in existence. The house of Hapsburg gained possession of it in the 11th c., and sold it in the 14th c. to the dukes of Württemberg.

TECTIBRANCHIA' TA, an order of gasteropodous mollusks, having the gills arranged only on one side, resembling pinnatifid leaves, and covered by the mantle and a small shell. The tectibranchiata feed mostly on sea-weeds, but some of them also eat animal substances. To this order belongs the sea-hare of the Mediterranean (*aplysia depilans*), which is sometimes a foot in length, and was in former times an object of superstitious dread, on account of its grotesque form, and of a violet-colored fluid which it ejects from the inner surface of the mantle when molested, and which was supposed to be poisonous.

TECUMSEH, or **TECUMTHA**, about 1768-1813; chief of the tribe of Shawnees; b. near the site of Springfield, Ohio. With his brother, Elskwatawa, who claimed the gift of prophecy, he attempted to form an alliance of all the western tribes against the whites. A village of about 400 warriors was gathered at Greenville, and they were ordered to remove by gen. Harrison, who was then governor of the territory of Indiana. Various hostile movements on the part of Tecumseh's forces led to the battle of Tippecanoe, Nov. 7, 1811. Harrison was at the head of about 800 men, and was attacked by Tecumseh in his own camp. The whites repulsed and defeated the Indians. Before a treaty had been concluded with the tribes, the war of 1812 broke out and Tecumseh allied himself to the British forces. He took part in the battles on the Raisin river and at Maguaga; was wounded in the latter, and made brig.gen. in the British forces for his services. At fort Meigs he showed humanity in his treatment of prisoners. The field of battle at the Thames was selected by Proctor and Tecumseh, the latter commanding the right wing. He was killed while fighting desperately. A life of the great Indian chief was written, 1841, by Benjamin Drake.

TE DEUM (*Te Deum laudamus, Te Dominum confitemur*), a well-known hymn (so called from its first words) of the Roman Catholic church, sung on all occasions of triumph and thanksgiving, and a theme upon which the most celebrated composers have from time immemorial exercised their musical genius. The hymn is one of the most simple, and at the same time the most solemn and majestic, in the whole range of the hymnology of the Roman Catholic church. Its authorship is uncertain. An ancient chronicle (long posterior, however, to the supposed date of the composition of this hymn, and otherwise destitute of authority) describes the Te Deum as the joint production of Sts. Ambrose and Augustine, into which they both burst forth by a common inspiration on occasion of the baptism of Augustine. From this supposed origin, the Te Deum is commonly called the Ambrosian hymn. It is ascribed by other authorities to Hilary of Poitiers, but is most probably considerably later. Besides its general use on occasions of joyous celebrations, the Te Deum forms part of the daily "matins" of the Roman breviary, and is recited at the end of "matins" on all festivals, and on all Sundays except those of Advent and Lent, to which, as being seasons of penance, the Te Deum is considered inappropriate. Its use is very ancient. It is universally admired by Protestants as well as Roman Catholics, and exhibits none of the peculiarities of Roman Catholic theology.

TEEL-SEED. See OILS and RAM-TIL.

TEES, a river in the n. of England, is 90 m. long, flows east, forming the boundary between the counties of Durham (q.v.) and York (q.v.), and falls into the North sea, 10 m. below Stockton, to which town it is navigable for vessels of 60 tons burden.

TEETH, **THE**. A tooth is described by prof. Owen, the highest authority on this subject, as "a hard body attached to the mouth or commencement of the alimentary canal, partially exposed when developed. Calcified teeth are peculiar to the vertebrates, and may be defined as bodies primarily, if not permanently, distinct from the skeleton, consisting of a cellular and tubular basis of animal matter containing earthy particles, a fluid, and a vascular pulp."—*The Anatomy of Vertebrates*, 1866, vol. i. p. 359. "They present," says the same writer, "many varieties as to number, size, form, structure, position, and mode of attachment, but are principally adapted for seizing, tearing, dividing, pounding, or grinding the food.* In some species they are modified to serve as formidable weapons of offense and defense; in others, as aids in locomotion, means of anchorage, instruments for uprooting or cutting down trees, or for transport and working of building materials. They are characteristic of age and sex; and in man they have secondary relations, subservient to beauty and to speech. Teeth are always intimately related to the food and habits of the animal, and are therefore highly interesting to the physiologist; they form, for the same reason, important guides to the naturalist in the classification of animals."—*Circle of the Sciences; Organic Nature*, vol. i. p. 264.

True teeth consist of one, two, or more tissues, differing in their chemical composition and in their microscopical appearances. "Dentine," which forms the body of the tooth, and "cement," which forms its outer crust, are always present; the third tissue, the "enamel," when present, being situated between the dentine and cement. The *dentine*, which is divided by prof. Owen into hard or true dentine, *vaso-dentine*, and

* Hence the division of the teeth into incisors, or cutting teeth; molars, or grinding teeth; etc.

osteo-dentine, consists, according to that physiologist, of an organized animal basis, disposed in the form of extremely minute tubes and cells, and of earthy particles; these earthy or calcareous particles being either blended with the animal matter of the interspaces and walls of the tubes and cells, or contained in a minutely divided state in their cavities. The tubes and cells contain, besides the calcareous particles, a colorless fluid, which is probably transuded blood plasma, or *liquor sanguinis*, and contributes to the nutrition of the dentine. In hard or true dentine, the *dental tubes* proceed from the hollow of the tooth known as the *pulp cavity*, in a slightly wavy course, nearly at right angles to the outer surface. "The hard substance of the tooth is thus arranged in hollow columns, perpendicular to the plane of pressure, and a certain elasticity results from these curves; they are upright where the grinding surface of the crown receives the appulse of the opposing tooth, and are horizontal where they have to resist the pressure of contiguous teeth. The tubuli, besides fulfilling the mechanical ends above stated, receive the plasma transuded from the remains of vascular pulp, which circulates by anastomosing branches of the tubuli through the dentine, maintaining a sufficient, though languid vitality of the system. The delicate nerve-branches on the pulp's surface, some minute production of which may penetrate the tubuli, convey sensations of impressions affecting the dentine—sensations of which every one has experienced the acuteness, when decay has affected the dentine, or when mechanical or chemical stimuli have "set the tooth on edge;" but true dentine has no canals large enough to admit capillary vessels with the red particles of blood." When a part of the primitive vascular pulp from which the dentine is developed remains permanently uncalcified, red blood is carried by "vascular canals" into the substance of the tissue. Such dentine is called *vaso-dentine*, and is often, combined with true dentine in the same tooth, as, for example, in the large incisors of certain rodents, the tusks of the elephant, and the molars of the extinct megatherium. Another modification of the dentine is when the cellular basis is arranged in concentric layers around the vascular canals, and contains "radiated cells," like those of bone; this is termed *osteo-dentine*, and resembles true bone very closely. The *cement* always corresponds in texture with the osseous tissue of the same animal, and wherever it occurs in sufficient thickness, as on the teeth of the horse or ox, it is traversed like bone by vascular canals. Moreover, when the osseous tissue contains minute radiated cells, precisely similar cells are likewise present in the canal, and constitute its most marked characteristic. The relative densities of dentine and cement vary according to the amount of earthy matter. In the complex grinders of the elephant and some other animals, the cement, which forms nearly half the mass of the tooth, wears down sooner than the dentine. The *enamel* is the hardest of all the animal tissues, and contains no less than 96.4 per cent of earthy matter (mainly phosphate of lime), while dentine contains only 72 per cent, and cement and ordinary bone 69 per cent of earthy matter. The earthy matter is contained in comparatively wide canals, composed of animal membrane of extreme tenuity.

In tracing the teeth upward from their simplest to their most complicated forms, we find a very few examples (solely among fishes—as, for example, the wrasse), in which teeth consist of a single tissue—a very hard kind of non-vascular dentine. Teeth consisting of dentine and vaso-dentine are very common in fishes, the hard dentine being external, and performing the office of enamel. Dentine and cement, the latter forming a thick outer layer, constitute the grinding teeth of the dugong. In the teeth of the sloth, the hard dentine is reduced to a thin layer, and the chief bulk of the tooth consists of vaso-dentine internally, and a thick crust of cement externally. "The human teeth and those of the carnivorous mammals appear at first sight to be composed of dentine and enamel only; but their crowns are originally, and their fangs are always covered by a thin coat of cement. There is also commonly a small central tract of osteo-dentine in old teeth. The teeth called compound or complex in *mammalia* differ as regards their composition from the preceding only by the different proportion and disposition of the constituent tissues. Fig. 1 is a longitudinal section of the incisor of a horse; *d* is the dentine, *e* the enamel, and *c* the cement, a layer of which is reflected into the deep central depression of the crown; *s* indicates the colored mass of tartar and particles of food which fills up the cavity, forming the 'mark' of the horse-dealer."

Organic Nature, vol. 1 p. 267. Far more complex forms of teeth than this may be produced by peculiar arrangements, chiefly inflections, of the tissues. Certain fishes, and a family of gigantic extinct batrachians, to which Owen has, from this remarkable peculiarity, given the name *labyrinthodonts* (q.v.), exhibit this kind of complexity in a remarkable degree. Another kind of complication is produced by an aggregation of many simple teeth into a single mass. These compound teeth are most common in fishes, but are occasionally met with in mammals. The teeth of the Cape ant-eater (*orycteropus*), depicted and described by Owen in *The Creole of the Sciences*, are of this kind, each tooth being composed of a congeries of long and slender prismatic denticles of dentine, which are cemented together. In the ele-

FIG. 1.—Longitudinal section of the incisor of a horse.

plant, the compound molars belong to this class, the denticles being in the form of plates vertical to the grinding surface, and transverse to the long diameter of the tooth. When the tooth is bisected vertically and longitudinally, the three substances, dentine, cement, and enamel, are seen blended together.

Our limited space forbids our entering into any details regarding the teeth of fishes, further than to remark that, in regard to their number, form, substance, structure, situation, or mode of attachment, they offer a greater and more striking series of varieties than do those of any other class of animals. In all fishes, the teeth are shed and renewed, not once only, as in mammals, but frequently during the whole course of their lives; and, as prof. Owen observes, "this endless succession and decadence of the teeth, together with the vast numbers in which they often co-exist in the same fish, illustrate the law of vegetation or irrelative repetition, as it manifests itself on the first introduction of new organs in the animal kingdom." While comparatively few fishes are entirely devoid of teeth, we find that in the class of reptiles, the whole order of *chelonia* (tortoises and turtles), the family of toads (*bufonidae* in the order of *batrachia*), and certain extinct genera of *sauria* (lizards) are toothless. Frogs have teeth in the upper, but not in the lower jaw. Newts and salamanders have teeth in both jaws and upon the palate; and teeth are found on the palate as well as on the jaws of most serpents. In most lizards, and in crocodiles, the teeth are confined to the jaws. The teeth in reptiles are for the most part simple, of a conical form, and adapted, as in the case of most fishes, for seizing and holding, but not for dividing or masticating the food. In no reptile does the base of the tooth branch into fangs; and, as a general rule, the base of the tooth is ankylosed to the bone which supports it. The completion of a tooth is soon followed by preparation for its removal and succession, the faculty of developing new tooth-germs being apparently unlimited in this class. For further details regarding the teeth of fishes and reptiles, the reader is referred to prof. Owen's invaluable *Anatomy of the Vertebrates*, 1866, vol. i. pp. 359-409. Birds having no teeth, we proceed to the consideration of the dental system of mammals—a class which includes a few genera and species that are devoid of teeth. The true ant-eaters (*myrmecophaga*), the pangolins or scaly ant-eaters (*manis*), and the spiny monotrematous ant-eater (*echidna*), are strictly toothless. The ornithorhynchus has horny teeth, and the whales (*balena* and *balanoptera*) have transitory teeth, succeeded in the upper jaw by whale-bone. The female narwhal exhibits nothing more than the germs of two teeth in the substance of the upper jaw; in the male, one of these germs becomes developed into the remarkable weapon which specially characterizes the animal, and to which its generic term *monodon* (single tooth), is due. In the great bottle-nose whale, in the adult state, there are only two teeth (here occurring in the lower jaw); whence the name *hyperoodon bidens*. The elephant has never more than one entire molar, or parts of two, in use on each side of the upper and lower jaws; to which are added two tusks, which are modified incisors, more or less developed, in the upper jaw. Some rodents have two grinders on each side of both jaws, which, added to the four cutting-teeth in front, make 12 in all; but the common number of teeth in this order is 20, although hares and rabbits have 28 each. The number of teeth, 32, which characterizes man, the apes of the old world, and the true ruminants, is the average one of the class mammalia; but according to prof. Owen, "the typical number is 44." "I have been led," he observes, "chiefly by the state of the dentition in most of the early forms of both carnivorous and herbivorous mammalia which flourished during the eocene tertiary periods, to regard three incisors, one canine, and seven succeeding teeth on each side of both jaws, as the type-formula of diphyodont* dentition."—*On the Classification and Geographical Distribution of the Mammalia*, 1859, p. 18. A few of the monophyodonts possess from 80 to 100 teeth. See the article MAMMALIA. The hog, the mole, the gym-nure, and the opossum, are among the few existing quadrupeds which retain the typical number and kinds of teeth. The formula expressing the number of the different kinds of teeth—viz., the incisors or cutting-teeth, the canines or dog-teeth, the premolars, and the molars or true grinder, commonly known as the *dental formula*, is described in the article DENTITION, in which the milk or deciduous teeth, and the order in which they appear, are also described. It is only in the mammals that we have a well-marked division of the teeth into the four kinds of incisors, canines, premolars and molars, each of which claims a brief description.

The *incisors*, or cutting-teeth, are situated in front, and possess a single conical root or fang, and a vertical crown beveled behind, so as to terminate in a sharp cutting edge. These teeth are specially fitted, as their name implies, for cutting the food. In man, there are two of these incisors in each side of each jaw. In herbivorous animals, they crop the herbage; in rodents (the rabbit, hare, rat, beaver, etc.), these teeth are very much developed, and differ from any other teeth occurring in mammals in this respect, that their growth continues throughout life; and if their length does not con-

* Professor Owen divides the class mammalia, in regard to the times of formation and the succession of their teeth, into the *monophyodonts* (Gr. *μῆνο*-, once; *phy*-, generate; and *odont*, tooth), or those that generate a single set of teeth, as the sperm whales, dolphins, porpoises, armadillos, and sloths; and the *diphyodonts* (derived from *di*, twice, etc.), or those that generate two sets of teeth, as the mammals generally, with the above exceptions.

stantly increase, it is because their free extremity or edge is worn down by trituration as fast as they grow at the base from their roots.

The *canines* (so called from their prominence in the dog) come next to the incisors. Their crown is rather conical than wedge-shaped, and their fang sinks more deeply into the jaw than in the case of the incisors. In all carnivorous animals, they are largely developed, being obviously formed for tearing the flesh of their prey. In man, there is one canine tooth in each half-jaw; and there is never more than this number in any of the lower animals.

The *premolars* (known also as bicuspid and false molars) come next in order to the canines; they are smaller than the latter, and their crown presents two pyramidal eminences. In man, there are two premolars in each half-jaw. Their function more nearly approaches to that of the true molars behind them, than to that of the canines.

The *true molars* (or multicuspid) are placed most posteriorly. They are remarkable for their comparatively great size, the square form of the upper surface, on which are from three to five elevations or cusps, and for their short root, which is divided into from two to five branches, each of which is perforated at its extremity. In man there are three molars in each half-jaw, the posterior one being termed the wisdom-tooth from its being cut the latest; they are especially employed for grinding the food, under the action of the muscles of the lower jaw.

The teeth are so admirably adapted for the special purposes which they are called upon to fulfill, that it is generally easy, from a careful examination of them, to say to what class of animals they belong, and to draw various conclusions regarding the habits and structure of the class generally. Thus, in carnivorous animals, the molars are not grinding teeth, but present sharp cutting edges, and those of the upper and lower jaw overlap each other; resembling a pair of scissors in their action. In insectivorous animals, the molars have a tuberculated surface, with conical points and depressions, so arranged as to look into each other. In frugivorous animals, living on soft fruits, these teeth are provided with rounded tubercles, while in herbivorous animals, they have a broad, rough surface, resembling a millstone.

There is also a close connection between the articulation or joint of the lower jaw and the nature of the food used by the animal. Thus, in purely carnivorous animals, in which the teeth simply tear and cut the food, no grinding motion is required, and the jaw is capable only of a simple hinge-motion in the vertical plane; while in herbivorous animals, the joint is so constructed as to allow of extensive sliding and lateral motion of the lower molar teeth upon the upper. In man, both the form of this articulation and the general character of the teeth point to an intermediate position in relation to food, and form a good physiological argument for the mixed diet which general custom has decided to be most favorable and natural to our species.—For further information on this subject, the reader is referred, not only to the three works of the professor from which quotations have been made in this article, but to his splendid *Odontography* (1844), and to his article "Teeth," in *The Cyclopædia of Anatomy and Physiology*; to F. Cuvier, *Sur les Dentes*, etc., and to De Blainville's *Osteographie*.

DISEASES OF THE TEETH.—The dangers to which infants and children are exposed during the process of teething, are noticed in the article DENTITION; and we shall therefore here confine our remarks to the affections of permanent teeth, of which the following are the most important:

1. *Caries of the teeth*, usually commences in the dentine immediately below the enamel, a yellow or brown spot being observed on the surface of the tooth over the affected part. The tissue soon becomes softened, and a small cavity is formed, which, after a time, presents an external opening, in consequence of the unsupported enamel giving way. The substance of the tooth now decays more rapidly, and the caries gradually approaches the central or pulp cavity, which at length is opened. Hitherto, there has been little or no suffering, but now pain is experienced under the action of irritant substances, heat, cold, etc. Inflammation proceeding to suppuration takes place; the pulp is gradually destroyed by ulceration; and the body of the tooth, thus deprived of its nourishment, decays and leaves nothing but the outer coating of enamel, which then breaks away by degrees, till nothing but the fangs of the tooth remain, and these usually cease to give pain. Caries is not only a common cause of toothache, but frequently gives rise to obstinate headache, pain in the ear, deafness, squinting, impossibility of bearing the light (photophobia), and other anomalous symptoms, which immediately disappear upon the removal of the diseased tooth. In these cases, the tooth may never have ached, but will be found painful when pressed up or smartly struck. The primary cause of caries is constitutional, and it especially occurs in scrofulous and ill-nourished persons, or in those whose health is broken down by too frequent pregnancies, prolonged lactation, the abuse of mercury, etc. The direct or exciting causes are usually described as: (1) Such as destroy the integrity of the enamel, and thereby expose the dentine to the influence of irritant substances; or (2) such as operate upon the vital susceptibilities of the dental tissues. Among the former are acids and other corrosive substances taken into the mouth, sour eructations, the attrition of opposing surfaces of the teeth, and all kinds of mechanical violence; while among the latter may be mentioned hot and cold drinks, especially when taken in quick alternation. The excessive use of sugar is also commonly regarded as a cause of the disease. Many of the best dentists,

however, deny that acids (when taken medicinally) or the abrasion of the enamel can give rise to caries.

With regard to treatment, it may be observed that if the caries be slight and recent, the decayed portion must be removed, and the cavity filled up with gold, as described in the article DENTISTRY. "But," says Dr. Druitt, who on dental matters always quotes the opinion of Mr. Tonies, one of the greatest scientific authorities on the diseases of the teeth, "if the decay has advanced far toward the pulp cavity, or has laid that open, it may be necessary first to employ aperients and tonics, and use some application to deaden the sensibility of the tooth, so as to enable it to bear the stopping, and to protect it meanwhile from contact with food and saliva." Many a useless visit to the dentist might be avoided, if the patient would take an aperient dose of epsom salts two or three consecutive mornings; and after cleansing out the cavity with dry cotton-wool, would insert twice a day a plug of that substance, moistened in eau de cologne, or still better, in either of the following solutions: (1) Mastic solution, formed by dissolving a dram of mastic in an ounce and a half of eau de cologne; or (2) Etheral tincture of tannin, formed by dissolving a dram each of tannin and mastic in an ounce and a half of sulphuric ether. By these means a painful tooth may be often brought into a state in which it will bear stopping. The patient's sensations will warn him against drinking very hot or cold, or sweet or acid fluids, and against exposure to cold draughts of air. Whenever the teeth exhibit a tendency to rapid decay, general tonic treatment is indicated.

2. *Necrosis* is an affection which is characterized by blackness of the tooth and looseness in its socket. It may be caused by violence, accompanied with destruction of the nutrient vessels, or by inflammation of the pulp. If the tooth gives trouble, it must be extracted. Necrosis of the teeth is quite distinct from the very destructive necrosis of the dental alveolar processes and of the jaws generally, which results from the poisonous action of phosphorus fumes, or from the very similar affection which sometimes follows the eruptive fevers. For an account of the singular and terrible disease from which artisans employed in making lucifer-matches suffer, in consequence of their inhaling the fumes of phosphorus (probably in the form of phosphorus acid), which was first noticed in 1839, we may refer to a review of Von Bibra and Geist's exhaustive treatise (in German) on the subject in the *British and Foreign Medico-chirurgical Review* for April, 1848; and to an article on "Phosphorus Workers" in the fifth report of the medical officer of health. Reference is also made to the disease in the article PHOSPHORUS in this work. The necrosis and exfoliation of the alveolar processes and portions of the jaws in children, consequent upon the eruptive fevers, is accompanied by the shedding of the teeth; and according to Mr. Salter, surgeon-dentist to Guy's hospital, who was the first to describe its true nature, is essentially the same as the necrosis in phosphorus-poisoning, and, like it, is the result of the local application of a specific poison, generated within the individual, to the vascular parts of the teeth. For a description of this remarkable disease, and of the treatment to be adopted, we must refer to Mr. Salter's article on "Exanthematous Jaw-necrosis," in Holmes's *System of Surgery*.

3. *Alveolar abscess* may be defined as a suppuration around the fang or fangs of a tooth, usually carious, accompanied by absorption of the bony walls of the alveolar process, and enlargement of the little sac of pus or matter, which gradually makes its way to the surface, "either along a canal by the side of the fang of the tooth opening at the edge of the gum, or through the gum itself at a point corresponding to the end of the root (or roots) of the tooth implicated. When, however, the fangs are unusually long, or the reflection of the mucous membrane from the gum to the cheek or lip is very superficial, this same discharge may burrow still more outwardly, and find its exit upon the surface of the face."—Salter, *op. cit.*, p. 2. When the discharge bursts, as it most commonly does, through the gum, the alveolar abscess is reduced to its simplest form, and is known as a *gun-boil*. When the discharge takes place in the region of the cheek or chin, the true nature of the case may easily be mistaken by a careless surgeon, who might refer the symptoms to bone-disease. The cause of this affection is either caries or necrosis. In its earliest stage the disease may be cut short by the extraction of the affected tooth, or even by the removal of the stopping, if the tooth is a stopped tooth. If it is desirable to save (for appearance's sake or otherwise) a threatened tooth, the gum should be freely leeched, and hot fomentations applied to the swollen part of the face, and the system should be briskly purged. As soon as matter can be detected it should be allowed to escape by a puncture made through the gum—an operation which is followed by immediate relief, and by rapid subsidence of the swelling, although pus continues to be discharged for a considerable time. Indeed, the disease seldom ceases altogether till the offending tooth is removed. When the abscess shows symptoms of pointing on the face, the tooth must be at once extracted, and more serious surgical interference will probably be necessary.

4. *Toothache* is not so much a disease as a symptom of various morbid states of the affected part, which, for convenience, may be classed under this single heading. "Toothache," says Dr. Wood, "offers every possible variety in degree, character, and duration. The pain runs through all the grades which intervene between a slight sensation of uneasiness and unsupportable agony. It may be dull, aching, heavy, sharp, pungent, throbbing, grinding, or lancinating. It may be continued or paroxysmal, remittent or intermittent, and regular or irregular in its recurrence. It may come, in

flashes, and as suddenly disappear; or may continue a long time with little variation."—*Practice of Medicine*, 4th ed. vol. 1. p. 512. According to the various conditions which give rise to it, toothache may be divided into: (a.) *Inflammatory toothache*, which is almost always dependent upon caries. The inflammation may be seated in the pulp of the tooth, in the nerve-twist entering the pulp-cavity, or in the periosteum investing its roots, and reflected over the interior of the alveolar cavity. There is generally some external swelling after the pain has continued for some time, and it occasionally extends to the salivary glands. The tooth is at the same time very tender, and any force applied to it aggravates the pain, which is also increased by hot and cold liquids taken into the mouth. When, as in the great majority of these cases, the pain is associated with caries, the best treatment is as follows: "Let the patient have a dose of calomel and colocynth; confine him to spoon diet; let him wash out the mouth with a solution of carbonate of soda in tepid water; let the gum around the tooth, and between it and its neighbors, if tumid and tender, be deeply scarified with a fine lancet; then let the cavity be filled loosely with a little bit of cotton-wool, dipped into the solution of tannin and mastic (for which the formula has been already given); and if the toothache be curable at all, this plan, with a little patience, will be almost sure to succeed. If the pain is very violent, half a grain of powdered acetate of morphia may be taken up with the cotton imbued with the tannin, which should be warmed before it is put into the cavity. As soon as the pain is relieved, the tooth, if of use, should be stopped with gold or amalgam; or if of no use, it should be extracted. It may be added that most of the violent, burning, empirical nostrums, such as creosote, oil of thyme, etc., although they may be of service when introduced in small quantity by a skilful hand into the carious tooth at the right time, can do nothing but mischief when employed indiscriminately, as they are by the vulgar."—Druitt's *Surgeon's Vade-mecum*, 8th ed. p. 458. (b.) *Neuralgic toothache* may occur either in sound or in carious teeth. It may be recognized by its occurrence in paroxysms at more or less regular intervals, and by its being attended with little or no swelling of the external parts. It is very common in the earlier months of pregnancy, and in persons of a general neuralgic tendency, and is often excited by changes in the weather. The treatment is the same as for neuralgia generally. After the bowels have been freely opened, chalybeates and quinine must be given in large doses, and frictions with veratrina or tincture of aconite (both of which are energetic poisons) may be carefully applied to the gum. (c.) *Rheumatic and gouty toothache* may occur in sound or in carious teeth in rheumatic or gouty persons. The constitutional treatment applicable to these diseases must be tried, together with the local applications already noticed.

5. *Fading of the teeth*, due to absorption of the socket, may be regarded as almost an ordinary consequence of old age; but it frequently occurs under the popular name of *scurvy of the gums* in middle age, although very seldom before the 30th year. True, scurvy, gangrene of the mouth, or mercurial inflammation of the gums, may cause the loosening of the teeth at any age; but there are two other conditions which lead to the same result. In one of these affections, the gums swell, and assume a deep red color, and the inflammation appears to be propagated into the alveoli, producing a thickening of the periosteum, and a consequent elevation of the tooth above its ordinary level. By frequently recurring attacks of this inflammation, the tooth is lifted out of its socket, while the gum retreats from the neck, and leaves a portion of the roots exposed. The tooth thus deprived of its support at length falls, after which the gum heals, and the patient is relieved. The remedies indicated are those tending to relieve inflammation of the gum, but they are seldom successful. In the other affection, there is conjoined suppuration of the gums and sockets, and the disease first shows itself by an oozing of pus from behind the edges of the gums when they are pressed. From the absorption of the sockets, and the simultaneous retreat of the gums, the teeth, as in the previous case, at length fall out, if they have not, for the patient's comfort, been previously extracted. Little can be done in the way of treatment in this form of the affection.

6. *Painful and difficult eruption of the wisdom-teeth* requires a few remarks. The cutting of these teeth is often accompanied by distressing symptoms, which may be protracted for months, or even years, unless surgical aid is called in. The difficulties "arise from the position occupied by these teeth, so close to the joint of the lower jaw, where the mucous membrane is reflected from the gums to the cheek and fauces; combined with the very common condition, that the jaw is not sufficiently elongated backward to allow the *dentes sapientie* to range in the horizontal series with the other teeth." This mechanical difficulty not only holds back these teeth in their bony bed, but it often prevents their proper direction of growth. As a consequence of these displacements in the upper jaw, it often happens that when the jaws are brought together, a bit of mucous membrane is nipped and pinched, leading first to ulceration and extreme tenderness, and subsequently to cicatrization and stiffness of the parts. From insufficient room in the lower jaw the crown only partially emerges through the gum, the first cusp coming through it, while the hinder cusps remain covered. This produces a terrible pinching of the mucous membrane over the tooth every time the jaws are brought in contact. Another troublesome symptom, often associated with the painful cutting of a lower wisdom-tooth, is spasmodic but continuous contraction of the masseter muscle, so as to keep the jaws nearly closed, and capable of only slight separation. The most distressing

result, however, is the suppuration that often attends the difficult eruption of the tooth. Even in ordinary cases, when none of these complications are present, there is often a good deal of diffuse and erratic pain in cutting a wisdom-tooth. It is unnecessary to enter into the treatment, which must be left entirely to the surgeon-dentist.

7. *Hemorrhage after extraction of teeth* has occasionally proved fatal, and is not very unfrequently a troublesome and even dangerous complication of the operation. In most of the recorded cases, there has been distinct evidence of the existence of the hemorrhagic diathesis, or, in other words, of a liability to bleeding profusely from the most trivial wounds. No better local treatment can be recommended than that which was suggested by John Hunter nearly a century ago. "In general, it will be sufficient to stuff the socket with lint, or lint dipped in oil of turpentine, and to apply a compress of lint or a piece of cork thicker than the bodies of the adjacent teeth, so that the teeth in the opposite jaw may keep up a pressure." Matico and saturated alcoholic solution of tannin may be equally efficacious as styptics, but are not superior to oil of turpentine. In some cases, the extracted tooth has been successfully replaced as a plug. The internal administration of astringents, such as tannin and oil of turpentine, should be combined with the local treatment.

8. The subject of *tartar* on the teeth has been considered in a separate article.

TEFF. See MEADOW GRASS.

TEFSA, **TADLA**, or **TEDLA**, a t. of Morocco, 135 m. n.e. of the city of that name, stands in the fertile, well-peopled district of Tadla, on the banks of the Um-er-Beg. It is one of the oldest towns of the country, and its manufactures of woolen cloths and shawls are important. • Together with the small town or suburb of Efza Tefsa contains 10,500 inhabitants, 2,000 of whom are Jews.

TE'GEA, an ancient city of Arcadia, Greece, said to have been founded by Tegeus, son of Lycaon. The inhabitants were noted for their courage, and were subdued by the Spartans only after a prolonged warfare. From Tegea came 3,000 soldiers to the battle of Platea and disputed the place of honor with the Athenians. They supported the Spartans in the Peloponnesian war, but after the battle of Leuctra joined the league, the formation of which brought on war with Sparta. The city resisted the attack of Lycurgus, but was captured by Machanidas, and afterward retaken by Philopæmen. A good account of the place is given by Pausanias. Its ruins are to be found near the modern town of Tripolizza.

TEGNER, **ESAJAS**, a Swedish poet of high reputation, was born in 1782 at Kyrkerud, in the Swedish province of Wernmland, and educated at the university of Lund, where he took the degree of M.A. in 1802. In 1805 he was appointed sub-librarian to the university, and lecturer on æsthetics. In 1811 the academy prize was awarded to Tegner's poem of *Seea*, or Sweden, which at once raised him to the rank of one of the most popular writers of his country. Prior to the appearance of this successful poem, he had written several spirited war-songs and national odes, which had attracted the favorable notice of the king and government. In 1812 he became professor of Greek, and at the same time was ordained to the pastoral care of the parish of Ståfje. During the next 10 or 12 years of his life, he devoted himself to the prosecution of his clerical duties, and the acquisition of theological learning, with an earnest and unwearying zeal which was scarcely to be expected from his previous indulgence in the pleasures of society, and his natural inclination toward the exhibition of a taste for coarse humor and equivocal puns. During this period, he composed his two famous religious idyls of *Prestrigelsen*, or the "Consecration of a Priest," and *Nattvardsbarnen*, or "The Young Communicants," and wrote his *Azel*, a poetic romance, which is regarded by some Swedish critics as even superior to his *Frithiof's Saga*, of which the first cantos appeared in a literary journal, edited by the historian Gejer, under the title of the *Iduna*, and conducted under the auspices of the Gothic society, the leading object of which was to foster national literature, and put down the prevalent taste for the pedantic classical or foreign school of writing. In 1825 Tegner published the closing parts of *Frithiof's Saga*, which rather errs in the opposite direction, and follows too closely the ancient saga on which the tale is founded. But notwithstanding the inharmonious character of the composition, which may be regarded rather as a collection of many ballads and odes in various meters than as a complete epic, the *Frithiof's Saga* became the most popular poem of Sweden, and attracted to its author the admiration and notice both of his fellow-clergy and of the sovereign, as was evinced in 1824 by the clergy of the diocese of Wexio nominating him for the vacant bishopric, and the king at once appointing him to the see. In his place at the diet, as a member of the chamber of the clergy, he made himself conspicuous for his support of ultra-conservative views, in opposition to the extreme liberal doctrines which he had advocated in early life. His speeches in the chamber and on numerous other public occasions have a great reputation in Sweden and Norway, and are devoted to the discussion of questions of education, literature, and finance. In 1839 Tegner was proposed for the archbishopric of Upsala; but in the following year, he was seized with unmistakable symptoms of insanity, which had been strongly manifested in two of his brothers and other members of his family. Although, after a few months' confinement in an asylum, he was able to return to his work, his health soon broke down; and after lingering for many months in a paralytic condition, he died in 1846. His collective

works were edited by his son-in-law, prof. Böttiger, and published in 6 volumes (Stock. 1848). All his larger and more popular poems have been translated into German, French, and English; the English translations of his *Frithiof* are very numerous, three or four new ones having appeared between 1873 (Spalding's) and 1879. Lorgfellow's is well known.

TEGUCIGALPA, a t. of Honduras, Central America, is situated on a table-land 3,426 ft. above the sea, 25 m. s.e. of Comayagua. Tegucigalpa is the largest and finest city in the state. In the vicinity are gold, silver, and copper mines; and in the n.w. of the dep. of which Tegucigalpa is the capital, is the mountain of Agalteca, a vast mass of pure magnetic ore. Pop. 12,000.

TEHA'MA, a co. in n. California; drained by the Sacramento river, and by Antelope, Red, Cottonwood, Beaver, and other creeks; traversed by the Oregon division of the Central Pacific railroad; about 2,500 sq.m.; pop. '80, 9,302—7,558 of American birth. The surface between the offshoots of the Sierra Nevada in the e., and the Coast range in the w., is a plain, without timber. The soil in the central parts is fertile. The principal productions are corn, barley, wheat, wool, live stock, and wines. Co. seat, Red Bluff.

TEHRAN', frequently spelled TEHERAN, capital of Persia, and of the province of Irak-Ajemi, 70 m. s. of the shore of the Caspian sea. It stands on a wide plain, dotted here and there with mud-built villages, and pierced with many circular pits, which reach down to the great subterranean water-courses, on which, in this region, the life of animal and plant is altogether dependent. On the n.e. runs the lofty range of the Elburz mountains, rising in Demavend to the height of 22,000 ft. above sea level, and giving dignity to an otherwise tame and unattractive scene. The town is built almost entirely of mud-houses, packed within a mud-wall 20 ft. high, and 4 m. in circumference. The principal buildings are the British and Russian residencies; the bázár of Taki Khan, finished in 1850-51, at a cost of £30,000; the ark, or citadel—in the suburbs—is the shah's palace, and about 2½ m. n. of these, the castle of the Kajars (Kasr-i-Kajar), the "Windsor" of the Persian rulers. Carpets are manufactured; but the chief trades are shoemaking and the manufacture of hats and linen goods. Several telegraph lines have been recently constructed, which center at Tehran; and they have compelled a number of European engineers and telegraph clerks to reside in Tehran, the number of European inhabitants in 1872 being estimated at about 50. Pop. in summer, 80,000; in winter, 120,000.—In the vicinity of Tehran are the ruins of Rei, the *Rhages* of Scripture, known in the time of Alexander the great under the name of *Rage*, and the birthplace of Harûn-al-Raschid.—See Eastwick, *A Diplomat's Residence in Persia* (2 vols. Lond. 1864); *History of Persia*, by Clements R. Markham (1874).

TEHUANTEPEC', a river-port of the s. of Mexico, in the territory of the same name, and 10 m. above the mouth of the river Tehuantepec, in the bay also of that name. The inhabitants, 15,000 in number, are engaged in manufacturing salt and cotton fabrics, and in indigo-planting. Pearl-fishing is carried on, and a purple dye is procured from a shell-fish which abounds in the vicinity.

TEHUANTEPEC' CANAL. See INTEROCEANIC SHIP CANAL.

TEHUANTEPEC', ISTHMUS OF, that geographical division of Mexico which extends between the gulf of Mexico and the Pacific ocean, in an e. and w. direction, and includes the political divisions Vera Cruz and Oaxaca. It comprises the Atlantic plains, which lie along the foot of the Cordilleras, on the gulf; the central mountainous districts; and the Pacific plains on the west. The basin of the Cootzacoalcos, and the contiguous territory, on the e. is a highly fertile alluvial country. This river rises in the Sierras, is navigable 30 m. from its mouth; and is important as offering one of the means for the projected canal connection with the Pacific. The Pacific plains average about 20 m. in width, descending gradually from the mountains. The population of the isthmus, principally Indians and half-breeds, numbers about 62,000; its productions are maize, coffee, cocoa, indigo, cotton, sugar, and tobacco. On the gulf side there are extensive forests of mahogany, cedar, gum, and india-rubber trees. On the western plains are great herds of cattle. The city of Tehuantepec on the river of the same name—which is merely a mountain torrent, thus dignified—is the second town in importance in the state (Oaxaca), and has about 13,000 Indians and half-breed inhabitants, with a few Spaniards. It is situated 11 m. from the Pacific; contains 16 churches, one of which was built by the last Zapoteco cacique in 1530, and possesses manufactures of pottery, cotton, shoes, hats, saddlery, etc. A portion of the isthmus was carefully surveyed by Cortes, who was seeking for an opening to the South sea—the great *desideratum* of the early Spanish navigators to America. Cortes, in fact, was the first to conceive of a method for connecting Asia with western Europe, *via* this isthmus. See INTEROCEANIC SHIP CANAL.

TEI'DE. See MONITOR.

TEIGITUR, one of the service-books of the Catholic church. It is properly but an extract from the Roman missal, and contains the canon of the mass, and certain other portions of the liturgy which do not vary with the variety of festivals or of the ecclesiastical seasons, but are always the same. It is so called from the first words of the

canon, *Te Igitur, Clementissime Pater*. This service-book, as distinct from the missal, was used, and is still used by bishops, prelates, and other dignitaries; and as the "canon" is the most sacred part of the service, oaths upon the *Te Igitur* were regarded as especially solemn. The *Te Igitur* appears to have been used as the ordeal "of compurgation."

TEIGNMOUTH, a sea-port market t., and favorite watering-place on the s. coast of Devonshire, on the n. side of the estuary of the Teign. In front, on the sea-side, is the wide esplanade known as the *den*, formed of a huge bank of sand, accumulated in the course of ages at the river's mouth—one of the chief features of the place. The harbor is safe and commodious, though difficult of entrance, the channel of the river being obstructed by a shifting bar of sand. The chief imports are coal and culm; the exports, granite from Dartmoor, and china-clay; there is also a considerable sea and river fishery. Teignmouth is connected with Shaldon, on the other side of the river, by a wooden bridge (completed in 1827) of 34 spans, 1671 ft. in length, with a swing over the main channel for the passage of ships. A large convent and educational establishment, founded by Miss English, was completed in 1865. The climate is mild and salubrious, and the country around beautiful. It is a station on the South Devon railway. Pop. '71, 6,751.

TEINDS, the name given in the law of Scotland to tithes (q.v.). In Scotland tithes were only paid from the produce of land or cattle. The teinds of corn, called *decimæ garbales*, greater teinds, or parsonage teinds, were generally exigible from all landed property, and originally paid to the rector or parson serving the cure, a small portion being claimed by the bishop. The tithe of the produce of animals, as wool, milk, cheese, was called lesser teind, or vicarage teind, because, where due, it was paid to the vicar; but vicarage teind was only legally exigible where a usage of paying it could be shown. The teinds, supposed to be due at common law to the incumbent of the parish, had, previously to the reformation, been largely diverted elsewhere (see *COMMENDATORS*); in some instances, they had been bestowed on some favorite religious house by the patron, who seemed to consider himself their absolute proprietor; in others, they had been feued to some layman. In many cases the religious house which had acquired the teinds, profited, or at least saved itself from odium, by selling them to the crown, or to a lay subject; and not unfrequently the pope, who was viewed as patron of all benefices to which no one else could claim a right of presentation, granted to the lands of churchmen an exemption from the payment of teind. At the reformation, the church-lands were claimed by the crown; those that had belonged to the religious houses were erected into temporal lordships, whose proprietors, called *lords of erection*, or *titulars*, were nominally burdened with the support of the clergy, by salaries modified out of a third part of the benefices. At the majority of James VI., it was found advisable to check the practice of granting the lands of religious houses to laymen; and the church lands were declared, with certain exceptions, to be inalienably annexed to the crown.

The right to tithes was, in Scotland as elsewhere, originally made effectual by their owner drawing the *ipsa corpora*, separating every tenth sheaf after the crop was reaped. But this proceeding often became an instrument of oppression, as the proprietor was obliged to allow his crop to remain on the ground exposed to all the vicissitudes of the season, until the beneficiary chose to draw his teind; and prior to the reformation, agreements had become common by which a certain quantity of grain, called *rental bolls*, was accepted in full value of teind, while leases were sometimes granted of the teinds for a money payment.

Various not very successful attempts were made during the reign of James VI. to regulate the conflicting interests of heritor and titular, and to provide the clergy with stipends which would not be illusory, out of the teinds of their respective parishes. Charles I., soon after his accession, issued, without the intervention of parliament, a revocation of all appropriations of church lands and teinds made during the two preceding reigns. The powerful barons who were possessors of church property at first menaced resistance, but eventually showed a desire for compromise, and the parties principally concerned entered into four submissions, in which they accepted his majesty's arbitration. The decrees arbitral pronounced by the king resulted in the establishment of valuations of teinds, and sales of them to the proprietor of the lands, by which the division of the produce between the owner of the land and the owner of the teind was avoided; and the teinds were made available to their utmost extent for the support of the parochial clergy. A commission, appointed to carry out the decrees arbitral, was continued from time to time till the union, when its authority came to be vested in the court of session, as court of the commission of teinds, the same tribunal which still exercises jurisdiction, both judicial and ministerial, in questions relating to teinds. A heritor, and in some circumstances the minister, may pursue an action of valuation of teinds; and a heritor may also insist on purchasing the teinds of his lands when valued, that is, in paying the value of the annuity in a lump sum. The modifying of reasonable stipends to the clergy, out of the teinds of their respective parishes, is one of the functions of the court of commission of teinds. The practice of augmenting stipends after they have once been modified was introduced with some hesitation; confined at first to stipends below the minimum, it afterward became general; and was recognized by act,

48 Geo. III. c. 138, which provides that no stipend can be augmented till 20 years have elapsed from a previous augmentation. By 50 Geo. III. c. 54, it was provided that the minimum annual value of any stipend should be £150; and if such amount cannot be made up by the teinds, it is supplied from the exchequer. See **STIPEND**.

The present position of the tithes of Scotland is as follows: In the majority of cases they have been purchased by the proprietors of the respective lands, after the modification of stipends to the ministers, and are held liable to the burden of augmenting those stipends to the extent of their value; in other words, there are no tithes, but part of the rent of the proprietors constitutes minister's stipend, and an additional part is liable to augmentation of stipend. A part of the tithes are in the hands of titulars, also liable to stipend and augmentation—they are, however, no longer drawn in kind; but paid according to valuation, or compounded for in the few cases where they remain unvalued. The teinds which were held before the reformation by the bishops and other dignified clergy, are in the hands of the crown, liable to augmentation of stipend. The teinds which remained in possession of the parochial clergy, still belong to them, but are commuted; and those belonging to colleges and hospitals have in most cases been valued, and are paid by composition, but have not been sold to the owners of the lands.

TEJADA. See **LERDO DE TEJADA**.

TEJUCIGALPA, a t. of Honduras, Central America, on the Rio Grande, here spanned by a handsome bridge. The exhaustion of its gold and silver mines and emancipation caused a large decrease in its population, but it remains the leading place of the state. The principal building is the cathedral, a fine specimen of architecture, containing the only public clock in the state.

TEKELI (more properly, *Tökely*), **EMERIC**, Count, a celebrated Hungarian patriot, was descended from a noble Lutheran family, and was born at the castle of Kasmark, in the county of Zips, in 1656. His father, count Stephen, had been implicated in the conspiracy of Zriny and Ragotsky to free Hungary from the rule of Austria; and after his death, and the execution of Zriny and others, young Tekeli sought an asylum in Poland, where he had large possessions. After vain endeavors to recover from the emperor his patrimonial estates, he repaired to the court of Abaffi, prince of Transylvania, who put him at the head of an army of 20,000 men, with which, in 1678, he invaded Hungary. Being joined by numbers of the malecontents, he rapidly extended his conquests, made predatory inroads even into Austria, Styria, and Moravia, till Leopold I. was forced (1681) to temporize with the insurgents, and thus gained over a portion of them. But Tekeli, distrusting with good reason the emperor's sincerity, refused to disarm, and being joined by the Transylvanian prince and the Turks, he was declared by the sultan Mohammed IV. (1682) king of upper Hungary, and again recovered most of the country. Tekeli joined Kara Mustapha in his celebrated inroad upon Austria; but after the failure of the expedition many of his followers fell off from him, and his patron, the sultan, being prejudiced by his enemies against him, he was twice imprisoned by the Turks; and during his detention Hungary was wholly overrun by the Austrians, and Transylvania separated from the Turkish alliance. Tekeli, however, was favored by a brilliant though ephemeral change of fortune in 1690, when, at the head of a Turkish force, he burst into Transylvania, routed the combined Austrians and natives repeatedly, and woke up the energies of his partisans in Hungary; but the imperialists, under the markgraf of Baden, routed his allies, the Turks, at Salankemen (Aug. 19, 1691), and under prince Eugene of Savoy, so completely demolished them at Zenta (Sept. 11, 1697), that they gladly agreed to the peace of Carlovits (Nov. 14, 1697), by which all aid to the Hungarian malecontents was withdrawn. From this time Tekeli lived in retirement in Turkey, at first being munificently entertained by the Turkish government, but afterward so completely neglected that he was forced to adopt the occupation of a vintner. He died at Constantinople in 1705.—His wife, Helena, the widow of Ragotsky, was celebrated over all Europe for her beauty, but was no less distinguished for her heroic gallantry, as was proved by her obstinate defense of her castle of Monatz (Hung. *Munkacs*) against an army of imperialists. Forced to surrender, to save the lives of her children and the property of her (Ragotsky's) family, she was afterward exchanged for an Austrian general whom Tekeli had captured; and joining her husband at the cost of abandoning her children, shared the vicissitudes of his fortune, and died in 1703.

TELAMONES (see **ATLANTES**), statues employed as columns to support a wall, cornice, etc.

TELEDU, *Mydaus meliceps*, a quadruped of the weasel family (*mustelidæ*), a native of the mountains of Java, at an elevation of 7,000 ft. and upward; remarkable, like the skunk (q. v.) of America, for the excessive fetor of a volatile secretion formed in glands situated a little within the rectum, the emission of which is its principal means of defense.

TELEGRAM, a communication sent by telegraph (q. v.). This word, which was coined some years ago by a writer in the *Times* newspaper, was objected to at the time by Greek scholars as a barbarous formation. According to the law of Greek compounds, *grapha*, compounded with anything but a preposition, becomes *grapheo*; therefore, with *têle*, it

would be *telegræphæo*, the noun from which would be *telegræphæma*. The convenient conciseness of *telegram* has, however, made it triumph over the more correct *telegræpheme*.

TELEGRAPH (Gr. *tele*, far off, and *grapho*, to write) is a general name for any means of conveying intelligence other than by voice or writing. The idea of speed is also implied. Alarm-fires (see BEACON), the semaphore (q.v.), and the signals (q.v.) used at sea, are among the earlier forms of telegraph. But all other agents are now thrown into the shade by the electric telegraph. It has been reserved for our own day to develop into practical use the capabilities of electricity and magnetism as a means of distant communication; although in earlier times, the possibility of such a use of this natural power has been frequently suggested. The public use of the electric telegraph dates not earlier than 1846; but the idea that magnetism could be applied for distant communication is at least two centuries and a half old. Galileo, in one of his dialogues on the rival astronomical systems, written in 1632, puts in the mouth of one of his speakers, a reference to a secret art, by which, through the sympathy of a magnetic needle, it would be possible to converse across a space of two or three thousand miles. In 1753, a letter appeared in the *Scots Magazine*, bearing the initials C. M., and headed "An Expeditious Method of Conveying Intelligence," in which we must recognize the first perception of the uses to which telegraphy might be put. This interesting letter starts with the remark that it "is well known to all who are conversant in electric experiments, that the electric power may be propagated along a small wire from one place to another without being sensibly abated by the length of its progress;" and it goes on to describe an arrangement of wires corresponding in number to "the letters of the alphabet, to be fixed in glass or jewelers' cement at intervals of 26 yards, and to convey, from an electric machine or rubber, a current which would lift each letter, "marked on bits of paper, or other substance that might be light enough" to rise to the electrified ball which formed the terminal of each wire. The apparatus proposed is crude and clumsy, yet we can hardly fail to recognize, in the letter of this Renfrew man, the full appreciation of what the electric telegraph might become. From a period shortly anterior to the date of the letter in the *Scots Magazine*, down to 1837, a large number of proposals, more or less ingenious, are on record. The space at our command will not permit us to describe all those inventions, or to enter upon the much-vexed question as to who is entitled to the name of inventor of the electric telegraph. We must be content to furnish a description of the more important instruments in use, some statistics of the more recent history of telegraphy generally in this country, and a notice of the progress of submarine telegraphy. In our description of instruments, etc., we shall assume the reader to be familiar with the chief facts of galvanism (q.v.) and electro-magnetism (see MAGNETISM).

Telegraph instruments may be classed under two heads, namely, those which record the signals, and those which only give passing signals to the observer or listener. Among the former are several kinds, namely, those giving a record in arbitrary signs (*i.e.*, in the dots and dashes of the Morse alphabet); those which print in ordinary characters, such as the Hughes type-printing instrument; and lastly, a class of instruments giving a *fac-simile* of the message. The latter two classes are not much used, and the number of Hughes instruments in use in this country has somewhat decreased. The great bulk of the telegraphing of the world is done either by the Morse printer, or by the non-recording instruments; and to those we shall therefore devote the major part of our description.

The Morse.—The leading principle in the Morse and other allied instruments is, that by the depression of a key or other method, an electric circuit is "closed" or completed, and a signal is transmitted along the wire to the distant station, where, on its arrival, it reproduces the signal by the action of an electro-magnet or otherwise. Electrically, the Morse consists of the transmitting key, (fig. 2) and the electro-magnet and armature (fig. 1);

FIG. 1.

while mechanically, it consists of a lever, with circular wheel or disk, attached to the armature, and a clock-work arrangement by which the paper tape to be printed upon is carried forward under the disk. Fig. 1 represents the electro-magnet and armature by which signals are received. On the current being received from the distant station, it traverses the coils of the electro-magnet E, and the armature F is drawn down by the action of the current. A and B are screws for regulating the play of the armature, and of the inking-disk I, at the other end of the lever. The instrument clerk is first required to adjust B so that the upper edge of the disk shall press gently against the paper tape (which is not shown in the engraving) and the screw A, so that the under surface of the disk shall dip into the ink-well or reservoir (likewise omitted in the diagram). B having been adjusted, the screw D is turned so that when the brass stop *f* rests

upon the stud *b*, the poles of the magnet shall clear the armature without actually touching it. A thin streak of light should be seen between the armature and the poles. Screw *C* is used to adjust the spiral spring above, by which, on the cessation of the electric current, the armature is drawn back and the disk ceases to mark the paper. In the first Morse instruments the marks were made on the paper with a pointed style (the instrument being thus known as the *embosser*); but by the invention of the ink-writing arrangement of Siemens, which we are now considering, the legibility and permanence of the record were secured, besides the advantage that a very light current will serve to make the marks. The case containing the clock-work, the arrangement of wheels by which the paper tape is unwound and carried forward, and the switch, by which the running of the tape is stopped, are not shown in the figure. The passage of a current draws down the armature, and elevates the disk, causing a straight mark on the tape so long as the current flows. When it ceases, the spring *S* draws back the armature as already described, and the mark is discontinued. Thus the duration of the current determines the nature of the mark, a momentary passage causing a dot, a longer depression of the key a dash; and as the alphabet invented by prof. Morse consists of dots or dashes, or a combination of the two, the above figure and explanation disclose the whole mystery of this system of telegraphy to those who have mastered the phenomena of electricity.

The Morse Alphabet.—Before going further, the details of this alphabet, universally recognized as a masterpiece of cryptography, may be given. The signals, as given below, are arranged in the groups, and accompanied by the mnemonic phrases, adopted by the British post-office when, in 1870, the transfer of the telegraphs to the government rendered necessary the rapid training of thousands of telegraphists throughout the kingdom:

<p>Group 1.</p> <p>.. E, Earwigs ... I, infest S, summer H, houses.</p>	<p>Group 2.</p> <p>— T, Turnips — — M, make — — — O, oxen — — — — Ch, cheerful.</p>
<p>Group 3.</p> <p>— — A, A — — — W, wet — — — — J, jacket's U, uncomfortable, V, very!</p>	<p>Group 4.</p> <p>— . N, No . . . D, difficulty B, baffles — . . G, great — . . . Z, zeal.</p>
<p>Group 5.</p> <p>— . . R, Remember! L, law — . . . P, preserves F, freedom.</p>	<p>Group 6.</p> <p>— . . . K, Kindness C, conciliates — Y, youth X, extremely — Q, quickly.</p>

The arrangement for the numerals is equally ingenious. Each figure is represented by five signals, thus:

1, . — — — —	6, —
2, . . — — —	7, — — . . .
3, . . . — —	8, —
4, —	9, — — — . .
5,	0, — — — — —

These are the numerals printed long, but on busy circuits expert clerks adopt the practice of "sending short," omitting all after the first dash in 1, 2, and 3, four of the dots in 5, and all before the last dash in 7, 8, 9, and 0. It is stated that prof. Morse founded his alphabet upon information given him by his brother, a journalist, as to the numerical relation of the letters in the English alphabet, the simplest signal (a dot) being given to E, and the next simplest (a dash) to T, those letters occurring most frequently in our language.

The Transmitting Key.—The "key" or hammer by which signals are transmitted from the operator at the sending office, is shown in fig. 2, in one of its earliest and most simple forms. The lever *l*, *l* turns on its axis *A*, and has on its under side two platinum nipples, *m* and *n*. *L* is the line-wire, connected with the axis; *E*, the "earth"-wire (passing through the Morse on its way to earth, and producing its signal there); and *C*, a wire connecting the stud *a* with the battery. As the key stands in the figure, it is in the position to receive a current from the distant station, the course of the current being *L*, *A*, *l*, *n*, *b*, and thence to the electro-magnet of the Morse *en route* to earth. When it is desired to send a current, the handle *H* is depressed, and the

FIG. 2.

current, generated in the battery, then comes by the wire C, and passing through *a*, *m*, and A, proceeds by the line-wire to the distant station. Various modifications of this key are in existence, but in all the principle remains the same, that the electric circuit is closed or completed by the depression of the key. The length of time during which the handle is depressed determines the length of the mark produced at the other end. Thus, if the clerk presses down the handle while he says "one—one two three," the ink-disk at the other end gives the mark . — (dot dash) or the letter A, and so on through the various letters of the alphabet.

The Battery.—For the generation of power in the electric telegraph, Daniell's batteries (see GALVANISM) are chiefly employed in this country. Various forms of the Bunsen battery are also used, especially on the continent. The power employed varies with the length of line, the condition of the wires as regards insulation, and the nature of the instruments used.

The Circuit.—The mode of joining up two stations by means of earth-wires, batteries, instruments, and line-wires, is shown in fig. 3. Assuming S and S 1 to be telegraph stations, P and P 1 are the "earth"-plates (see subsequent paragraph), B and B 1 the batteries, *n* and *n* 1 the electro-magnets and armatures, and *b*, *k*, *g* the transmitting keys and galvanometers. L, L show the line-wire, supported on poles and insulated. The key at station S is shown depressed, so that a current of electricity may be supposed to be passing from the battery B through the key and galvanometer along the

FIG. 3.

line-wire, and thence through *k* 1 and *n* 1 to the earth-plate P 1. Supposing, then, that the clerk at S desires to send a message to S 1, he depresses the key *k* several times so as to send a series of dots and dashes corresponding to the name (or rather the code signal representing the name) of the distant station. The attention of the clerk being gained by the clicking of the Morse, he turns the switch to set his paper tape in motion, gives the signal that he is ready, and the message is then sent.

The Line.—From fig. 3 some idea may be gained as to the mode of carrying a wire or series of wires over posts, these posts being carried along the sides of a road or railway. In towns, wires are carried "over-house," or by underground pipes, the wires in the latter case being insulated by means of a gutta-percha or other suitable covering. The subterranean method is being applied to extended lines, especially in Germany, and is found to answer as well as the over-head system, while it avoids many of the casualties to which the latter is liable. In pole and over-house lines, the wires are kept from each other and from contact with the earth by insulators of various kinds. White porcelain and brown stoneware are the chief materials used. The former, when of good quality, well glazed and well burned, is perhaps the most perfect of all insulating materials, and does not deteriorate with age. The fewer the poles are in number on which the wires are suspended, the better is the insulation and the less the cost, but the liability to accident is probably greater. The number of poles used varies from 16 to 30 per mile, and is governed by the number of wires carried, the configuration of the track, and other considerations. On road lines, the number of poles is generally larger than in the case of telegraphs carried alongside railways, the greater levelness and straightness of the latter reducing the number of supports required. The wire chiefly used for inland telegraph purposes is of iron, galvanized, and of No. 8 ($\frac{3}{8}$ in.) gauge. The conductivity of a wire increases in the ratio of the square of its diameter (the resistance decreasing in the inverse ratio), and the advantage of using a thicker wire on the longer lines is thus seen. No. 4 wire is, for this reason, used on some of the longer lines.

The Earth—Earth Currents.—Mention has been made of the "earth," in the preceding description. This is the technical expression used in relation to the fact discovered by Steinheil in 1838, that the earth itself serves the purpose of completing the circuit,

and renders the employment of a second or return wire unnecessary. The "earth" may consist of a buried plate of metal connected with the battery or line-wire, and of sufficient surface to afford the necessary diffusion. The gas or water pipes of a town form excellent "earths," care being taken that the connection is made with the pipe itself, and not with a branch, where a badly made joint might spoil the connection. Where dissimilar "earths" are in use, as for instance, a copper plate at one end, and an iron pipe at the other, a *quasi* battery is created, and vexatious currents pass along the line. Hence the "earths" on a circuit should be made alike. The earth, being regarded as a large reservoir of electricity, offers no sensible resistance to the passage of the current, in the same way as the ocean would receive or supply at any point an indefinite quantity of water. While this quality of the earth is one of the most valuable aids to telegraphy (reducing so materially the cost of wire erection), it presents at times those embarrassing interruptions known as *earth currents*. These currents, at all times unwelcome visitors to a telegraph office, are very variable, changing rapidly at times from positive to negative, altering their direction with the hour of the day, and leaving one circuit to appear on another in a manner not explainable. The lines most liable to such disturbances are those running n.e. and s.w.; that is, connecting places separated in a straight line in those directions, and without reference to the actual direction of the wires. The easiest remedy for earth currents, when they are of sufficient strength to affect the lines, is to dispense with the earth connection, and revert to the original plan of using two wires. Thus between places where there are two wires, both may be disconnected from "earth," and used as a complete metallic circuit. Another remedy has been found in extending the circuit by joining to it a further wire, the terminal point of which lies beyond the direction or line in which the earth current is flowing. We must refer to the larger treatises on telegraphy for information regarding lateral induction, velocity of electric discharge, the tests for resistance, insulation, etc., and also for notices of some of the less prominent pieces of apparatus now found in the instrument-room of the electrician.

The Relay.—We now proceed to notice several methods by which the transmission of signals is facilitated or accelerated. First among those may be placed the *relay*. Siemen's polarized relay is now in very extensive use in this country. In the previous description of the Morse, we have assumed the instrument to be worked directly by the current sent along the line. On long circuits, however, direct working could only be

FIG. 4.

FIG. 5.

accomplished by great battery power, as, owing to inevitable loss by leakage, a current loses greatly before it reaches its destination. It is found to be a much better arrangement to have the instrument worked by a "local current," derived from a local battery at the receiving station. The mode by which this is accomplished will be seen from the diagrams. In the figures, NS is a hard steel permanent magnet, whose s. end S has a slit, in which the soft iron armature, *a*, is pivoted. To this armature a thin aluminium tongue, *b*, is attached, which, by making contact at the point *c* (fig. 4), completes the local circuit. To the n. end, N, of the permanent magnet the soft iron cores of the electro-magnet are fixed, as shown in the sketch. When the armature is equidistant from the poles of the electro-magnet, it is equally attracted by both; but if it be brought nearer to one than to the other, it will be held there, because it is under the influence of a more powerfully attracting force. Since the relative distance between the armature and the two pole-pieces may be increased at will, the attraction between either pole and the armature may be regulated with any degree of nicety. The electrical contacts for

the local circuit are seen in fig. 4, which is shown with the local circuit completed. When two stations far apart are to be connected by telegraph, it is usual to transmit the signal to a half-way station, and thence to re-transmit it to its destination. The retransmission is not effected by manipulative skill, but by mechanical contrivance, so that, while the half-way station may read the message sent, no time is lost in the transmission. This is effected by making the intermediate instrument act as a relay in transmitting a message to the next station. The system, to be fully explained, would require more detail than we can here give to it. We shall only show how it is effected, leaving out of account how all the stations can communicate as in one circuit. The current C_1 , (fig. 5), from the sending-station enters the coil M , and goes thence to earth P , and returns as shown by arrow C_1 . The instrument may record or not as required, but its doing so in no way interferes with translation. The copper pole C , of the battery CC , is connected with the lever ll' of the register, and the zinc pole is to earth. When the lever is drawn down by the current C_1 , it strikes against the point at the top of the pillar p , that checks its motion. The pillar p is joined to line L_2 , running to the further station, and when the lever falls, a second circuit—viz., that of the battery CZ —is closed, in which C , the lever, the pillar L_2 , the further station, the earth, P , and Z are all included. Thus, as ll' prints at the intermediate station, it at the same time sends a new printing-current to the next. When it ceases to print, so does the instrument at the distant station.

Wheatstone's Automatic Transmitter.—The speed of the ordinary Morse instrument is limited to the rapidity with which the hand of the operator can move the key, so as to preserve the proper spacing between the marks at the receiving instrument. We are indebted to sir Charles Wheatstone for an apparatus which trebles, and in some cases quadruples the carrying capacity of a wire, securing, at the same time, mechanical accuracy in the relative size of the dots, dashes, spaces, etc. To effect this, three different instruments are required: First, there is a perforator, by which holes are punched in a paper slip to correspond with the signals required. The operator strikes three disks, the central one producing a central hole, which is of no avail electrically, only carrying forward the paper; the left-hand disk producing two holes, directly opposite to each other, on the sides of this central row; and that on the right producing two holes, placed diagonally to each other. The passage of the electric current is regulated by the position of the outer holes. Those opposite each other admit of a momentary passage of the current through the “transmitter”—used in sending the message—while the holes diagonally placed produce a lengthened mark, corresponding to the dash. The following diagram represents the word “and,” as shown on the punched slip:

```

      o o      o o o o o
    o o o o o o o o o o o
      c o      oo      o o o

```

As printed at the other end, this reads:

```

      —      —      —
      a      n      d.

```

The third portion of this instrument is the “receiver,” in which the currents sent by the action of the punched slips in the transmitter are reproduced in the dots and dashes of the Morse code—the printing being, moreover, done with a mathematical accuracy which keying by hand cannot attain. The speed of transmission depends on the length of line and state of the atmosphere; but the movement of the clock-work, both of transmitter and receiver, is capable of adjustment to any speed below 120 words per minute. When the post-office took possession of the telegraphs in this country, the Wheatstone automatic instrument was in use at only four stations in the kingdom. It has since come into extended use; and one of its most successful applications is in the simultaneous transmission of news from London to a large number of towns. The punched ribbon is carried from one transmitter to the other, the circuit to Birmingham, Manchester, and Liverpool (on which the highest speed is attained) sending it first, and from that instrument it passes to several others, each serving several towns. The adjustment of “resistance,” by which a message is run off simultaneously at Edinburgh, Glasgow, Dundee, and Aberdeen by one sending from London (and so through the various transmitters where this system of “express news circuits” is adopted), forms one of the most interesting objects of study in the practical working of the telegraph in this kingdom. By combining the automatic transmission with Bain’s principle of producing marks on chemically prepared paper, an American inventor has accomplished still higher speed, the lever action of the inking disk (fig. 1) being saved.

Other Instruments.—All that has been said as to the battery, the earth insulation, etc., is applicable to nearly every instrument now in use; the exception being several magneto electric instruments, such as Wheatstone’s “ABC,” in which the use of a battery is dispensed with, power being generated by two bobbins coiled upon an armature rotating continuously over the two poles of a permanent magnet. On the upper surface

of this instrument is seen a circle of buttons corresponding to the letters of the alphabet, by means of which levers, arranged vertically in a circle, may be pressed down. These levers press a pitch chain into a series of indentations on the periphery of a metal disk, the chain having sufficient slack, so that, when a second lever is depressed, the first must be raised. A series of currents, corresponding to the number of letters between each lever pressed down, is sent into the line, and operating on two little bent magnets, moves forward a ratchet wheel, having a pointer on the same axis which shows the letter on a dial card. In this way the message is spelled out letter by letter, and as the instrument gives not an arbitrary sign, but the letter itself, it is much used in private telegraphs and for the smaller post-offices throughout the kingdom. The non-recording instrument most used in this country (excluding private telegraphs) is the single-needle instrument of Cooke and Wheatstone. It consists of an upright galvanometer, with astatic needles, one of which moves within the coil, and the other upon the front of the dial. The needles are loaded at the lower end, to maintain them perpendicular when no current is passing. The instrument is worked by means of two keys, like those of a piano, a deflection of the needle to right or left being effected by depressing one or other of the keys. The signal is shown both on the sending and receiving instrument. The Morse alphabet is used, a deflection to the left corresponding to the dot, and one to the right representing the dash.

Acoustic Telegraphy.—Before the introduction of high-speed automatic instruments for the more important circuits, expert telegraphists in many cases dispensed with the reading of the printed slip, reading by the sound, which, by long practice, became a language perfectly intelligible to them. The great advantage of this was, that the use of the eye was obtained exclusively for the task of writing down the message. In Sir Charles Bright's "bell" instrument, most admirable results, in point of speed, have been attained. The bells, different in sound, are placed at the two sides of an upright instrument, so that the clerk, bending forward to write, may concentrate his attention on that duty, translating in his mind the tinkle of the hammers as they ring out their message. The bells are now worked in the Morse code—the left bell a dot, and the right bell a dash; but when first introduced, the instrument had a code of its own, based on the desire to complete each letter as much as possible on one bell. A simpler acoustic telegraph has been brought into use in America (hence called the "American sounder") and in this country. This instrument is, shortly stated, the Morse without its wheel-work and ink-printing apparatus; and its whole construction is shown in fig. 1, omitting the inking disk. The use of the "sounder" has greatly increased in this country owing to its cheapness and efficiency. For a description of the type-printing and *fac simile* instruments, on which great advances have been made of late years, we must refer our readers to the larger treatises on the telegraph and its history.

Duplex Working.—The fact that two currents may be sent simultaneously (one from each end) has been long recognized by electricians, but the principle of the duplex was revived and patented by Stearns, an American, in 1872. At first the duplex-working was only tried on short circuits of 40 to 60 m.; but it has now become a matter of daily use on every busy circuit, long or short, both in this country and abroad. The principle of the duplex system is that the current sent on the depression of the key is divided into two parts, one-half being carried through one pair of coils in a differential galvanometer to the line, and the other half through the other pair of coils to a resistance coil, and thus to earth. The resistance of the latter is made exactly equal to that of the line-wire, and the instrument of the sender being so placed that this divided current presses equally in each direction, this instrument remains unaffected, while the armature at the other end responds to the signal sent. At the same time a telegraphist at the other end is sending a current, which is divided in like manner, and leaves his own instrument unaffected while operating on the armature of the first instrument. The two currents on the line-wire assist or oppose each other in such a way as to affect the equilibrium in the differential galvanometer, but each operates only on the distant instrument. Duplex-working led to *duplex*, that is, two messages passing over a wire in the same direction at once, and to this has followed quadruplex and multiplex telegraphy. Quadruplex working was first perfected in 1876 by Prescott, Edison, and Gerritt Smith, but the possibility of its being accomplished was suggested by Stark of Vienna, in 1855. It was introduced into Britain as a practical branch in 1878, and is now used from London to Liverpool, Dublin, and other towns. An illustration of the value of these additions to the wire power is afforded by a wire from Chicago to Pittsburg, 550 m., which is quadruplexed, and at Pittsburg branches off in two duplex circuits to Baltimore and Philadelphia, giving Chicago duplex communication with these two places. In the same way Middlesborough and West Hartlepool have been duplexed to London, on separate wires as far as Leeds, and quadruplex on one wire thence to London.

Multiplex Telegraphy and "Phantom" Circuits.—The most original feature of the telegraph section of the Paris exhibition of 1878 was the harmonic telegraph of Haskins and Gray, based on principles laid down by Cromwell Varley in 1870. In one application it occupies a place midway between duplex and multiplex telegraphy, namely in the "way duplex," or as it was felicitously termed by the late Mr. Orton, the "phantom circuit." A wire may be occupied by the ordinary business of a series of intermediate

offices, while there may be superimposed on that a through traffic (which can be duplexed) between the terminal stations. Thus between Chicago and Dubuque, a wire provides for 17 intermediate stations, working ordinary Morse sounders, while the harmonic telegraph (the principle of whose action is vibratory currents sent and received by musical forks tuned in unison) works between the terminals. By an extension of this principle we have the multiplex telegraph, each fork taking off at the receiving end those vibrations corresponding to its own tone.

The Electric Pen.—Amid many endeavors to introduce an autographic telegraph that of Cowper, made public in 1879, is the most successful. It has the drawback of requiring two wires, but is so beautiful in its action as to deserve notice here. Two series of resistances are ranged like the letter **L**, one series affected by lateral, the other by the up-and-down motion of the sender's pen. At the other end a siphon recorder moves in accordance with the currents thus sent, giving on a moving slip of paper an exact *fac-simile* of the writing or other marks of the person sending the message.

Statistics.—In Great Britain the first public introduction of telegraphy was made in 1846 by the Electric and International Telegraph co. Subsequently the British and Irish Magnetic co. was established, and afterward the United Kingdom co., the last named being started on the footing of a low uniform rate, but eventually yielding to the opposition of the other companies, and adopting a sliding scale of rates. The charges were from 1s. to 6s., according to distance, for a message of 20 words. Besides these companies, there were the London District co., the Universal Private Telegraph co. (which established a series of public telegraphs, connecting Glasgow with places on the w. coast of Scotland), and a large number of railway companies, carrying messages between their own stations, besides acting as agents to collect business for the other companies. In 1868 and 1869, after some agitation of the question, acts were passed transferring the property of the telegraph companies to the post-office, and giving that department a monopoly in the conduct of telegraph business within the kingdom. The task set before the post-office was to reduce and simplify the charges, to separate entirely the public wires from wires used for railway purposes, to extend the telegraph to outlying places and to business parts of towns, and to establish free trade in press telegraphy—the meaning of the latter being that, instead of collecting and supplying news as the companies had done, the department should only arrange to transmit news, at specified rates, for all comers, leaving the newspapers to make their own arrangements for obtaining information. The great progress of telegraphy in the hands of the postal telegraphs department is one of social features of the time. Including a large number of new offices prepared for opening on the occasion, the post-office started in 1870 with 1007 telegraph stations, to which about 1900 railway stations receiving messages on behalf of the department fall to be added. In 1878 the number of offices belonging to the post-office was 3,756, making, when the railway stations are added, a total of 5,311 offices. It appears, however, that the railway offices only take in from the public 7 per cent of the messages sent. The mileage of wire under charge of the postal telegraphs department, and exclusively devoted to public business, in 1878, was 107,353, with 5,980 m. of private wires, for which rents are paid to the department. The number of messages before 1870 was estimated as reaching 6,000,000 annually, and the following gives the totals for three years since the telegraphs passed into the hands of the post-office:

	No. of messages.	No. of offices open.	Weekly average for each office.
Year ended Mar., 1871.	9,850,177	3,926	46
“ “ 1873.	15,535,780	5,540	53
“ “ 1878.	22,171,783	5,311	80

These statistics show that the growth of business had been so large as to raise the weekly average over the whole number of offices, the closing of many small railway stations also helping this result. So far as the cost to the public is concerned, it is shown that, while under the *régime* of the companies the cost per message averaged 2s. 1½d., the cost under the post-office reaches an average of under 1s. 1d. per message. Writing in May, 1872, Mr. Scudamore, under whose direction the transfer and extension of the telegraph system was conducted, says: “If the messages of the current financial year were to be paid for at the old tariff, they would cost the senders at least £400,000 more than they will cost.” The revenue for 1877-78 was £1,333,542, including in this private-wire rentals, newspaper special wires, etc. The capital invested in the undertaking amounts to about ten millions sterling. The cost of working in 1877-78 was £1,164,131: the staff consisting of 406 persons in the central control of the system (secretary's and accounting offices); 650 in the engineering department (for maintenance and extension of the system); a staff of 1770 in the central office at London: and the services of postmasters, telegraphists, etc., throughout the kingdom, making a total of above 11,400 persons engaged in the service. Of these, 4,981 were messengers engaged in the delivery of messages, the larger portion of whom were supplied with uniform. In addition to electric means of

communication, the post-office uses pneumatic tubes in London and other cities to connect the larger branch offices with the principal station in each case. As those tubes, although forming an interesting branch of the apparatus, are not, strictly speaking, electrical, we must refer to other sources for information as to their construction, mode of working, power used, etc. The result of the transfer from private hands to the control of the government may be summed up in saying that for efficiency, comprehensiveness, and public appreciation, the telegraph system in Great Britain is now second to none in the world. The continent of Europe forms one vast network of telegraph lines. By means of submarine cables (as afterward noticed), the offices in this country are connected with all the four continents, while recent extensions have brought the Australian colonies also into connection with the other sections of the globe. While each kingdom fixes its own internal tariffs and regulations, the rules for the interchange and transmission of telegraph messages between the various countries of the world are regulated by telegraph conventions agreed to at Paris, Vienna, Rome, St. Petersburg, and London (the last named being held in 1879); and all official intimations in connection with international telegraphy are issued from a central bureau in Berne, Switzerland. To the mountain republic the world is indebted, not only for the example of an excellent and cheap internal system, but for the suggestion of this central administration, where all international matters are conducted. In France and Belgium internal telegraph arrangements are complete and cheap; while the United States for many years held a place far in advance of other countries in the ordinary every-day use of its great telegraph organizations. Perhaps the most striking instance of telegraph enterprise is that by which the daily newspapers of San Francisco are enabled to give, by means of a line of telegraph carried over the Rocky mountains (on the line of the Central Pacific and Union Pacific railroads), not only the news from New York, but the parliamentary news from London, the prices of all the continental exchanges, and quotations from Calcutta and China of the previous day.

Submarine Telegraphy.—From the year 1850, when a copper wire insulated with gutta-percha, submerged between Dover and Calais, continued in use for one day, the progress of submarine telegraphy has been as remarkable as that of telegraphy on *terra firma*. The Malta-Alexandria cable was laid in 1861, and continued in use till 1872, when, from repeated breakages in shallow water, its use was discarded. The core consists of a strand of seven copper wires, covered by three layers of gutta-percha; outside of this, a serving of tarred yarn; and, finally, eighteen iron wires, constituting the sheathing. This was the first long cable successfully laid (its total length, in three sections, being 1331 miles); and it was also the first properly tested under water before being laid, and carefully constructed with constant watchfulness as to its electrical and mechanical conditions. This cable was thrown out of use because the chafing it underwent in shallow water made it too expensive in maintenance. So far as construction goes, it corresponds very nearly with sir James Anderson's typical "successful iron-covered cable." With careful testing and supervision, and with the weight of cable, etc., duly proportioned to the strain, etc., a cable forms a permanent property of much value. A new form of cable, with lead as the conductor, has been suggested. In 1877 the task of duplexing a submarine cable was accomplished by Muirhead on the Aden and Bombay cable of the Eastern Telegraph company, and the "artificial line," or balance, has been since applied successfully to other cables, including two crossing the Atlantic. In view of the enormous cost of submarine telegraphy, the attainment of a means by which the carrying capacity of a cable is nearly doubled is of vast importance. In 1877 the Marseilles-Algiers cable, belonging to the French system, was duplexed by M. Ailhaud. The *Journal Télégraphique* gave in 1877 a list of 149 cables belonging to companies, and 420 belonging to government systems, existing at that date. In point of number, Norway stood first, with 193 cables, but the total length of these is only 233 nautical miles. The total length of the 420 government cables was 4,442 nautical miles, of which Britain possessed 49, measuring 1338 miles. The longest of these (excluding cables to the continent) is to Guernsey 70, and to Shetland 63 miles. The company cables (of which 96 per cent had their administration in London) measured 59,547 nautical miles. The longest cable is that from France to America, 2,585 nautical miles, and the largest organization that of the Eastern and Eastern Extension companies, embracing 48 cables of a total length of 21,883 nautical miles, to which, since 1876, several thousand miles have been added in new routes or duplicated cables. In 1879 Great Britain was connected with Europe by eighteen cables, and with Ireland by five cables. From Europe to America seven cables crossed the Atlantic (five from Ireland, one from France, and one from Portugal to Brazil). A cable from Nagasaki to Shanghai joins the internal system of Japan with the outer world; while by cables of 557 miles from Singapore to Batavia, and 1082 miles from Java to Australia, the distant colonies are brought into the telegraph system of the world. Many additional cables, including one to Natal and the Cape, are projected or in course of construction; and before long it cannot be doubted that the imagination of the poet, to "put a girdle round the earth in forty minutes," will be cast into the shade by the realities of the electric telegraph.

See works on *Practical Telegraphy* by Culley, Sabine, Preece and Siveright, etc.;

Journal of the Society of Telegraph Engineers; sir James Anderson's Lecture before the statistical society, London, June 1872; Mr. Scudamore's reports to the postmaster-general, 1870 and 1872; estimates for the telegraph service, laid annually before parliament, etc.

TELEGRAPH (*ante*). The practical application of the scientific laws under which the telegraph operates—in the form of the instrument still, with certain modifications, in general use—is supposed to have been first made by S. F. B. Morse (q.v.) in 1832–35. In 1828 a similar idea was demonstrated by Harrison Gray Dyar, of New York, in an instrument which transmitted frictional electricity through a wire, the charges being recorded by being passed through a moving sheet of litmus paper. It is alleged that the same principle had been demonstrated nearly a century before in Scotland; in 1774 in Geneva, Switzerland; and in 1816 in England, by Ronalds. The first *telegraph line* in operation was between Paddington and Drayton, in England, in 1835, and was 13 m. in length. This antedated the Morse line, which was laid between Washington and Baltimore, by seven years. The printing telegraph was first invented by Alfred Vail, of New Jersey, in 1837, but it was not until 1841 that Wheatstone made his first model of the instrument. In 1845 Mr. C. J. Fleischmann exhibited the Morse apparatus to the emperor of Austria, at Vienna, and with such success that it was adopted by the Austrian government. In 1848 two Americans built a line between Hamburg and Cuxhaven at the mouth of the Elbe, a distance of 90 miles, which was operated on the American plan with Morse instruments, and was employed for reporting marine news. The Wheatstone apparatus did not work well except through comparatively short distances, and at a very low rate of speed, and was altogether inferior to the Morse telegraph. The superior efficiency of the latter in working direct through long distances was caused by the application of the relay and local circuit. In Oct., 1851, a convention met at Vienna of deputies from Austria, Prussia, Bavaria, Württemberg, and Saxony to effect a common and uniform telegraph system. By this convention it was decided that the Morse system was practically the best, and this was therefore adopted. In the beginning of Morse's experiments he made use of the fountain-pen and other devices for recording the characters; but in the end the stylus or steel point for embossing these was found to be the most convenient and satisfactory.—The telegraph business in the United States has long tended toward concentration and consolidation. Gradually the various companies that have from time to time been formed have been bought up, until the Western Union telegraph company represents nearly the entire scope of this interest in the country. This result has been achieved mainly by the purchase of valuable patents, among which those of Edison have been perhaps the most important. As to these, including the quadruplex system, see EDISON, THOMAS A. The number of telegraph offices in the United States on July 1, 1879, was 8,534, the total length of lines, 82,987 m.; and the length of wires, 211,566 m.; the number of messages transmitted in the United States during the year ending June 30, 1879, was 25,070,106.

Within the past few years there has been an important and comprehensive movement in the direction of ocean telegraphy, which had previously for a considerable period been comparatively neglected. English companies have laid three long ocean cables in the east; and a French organization of capitalists have laid a transatlantic double line. The duplication of the lines of the Eastern telegraph company from England to Bombay was completed in 1878. A similar duplication on the part of the Eastern extension telegraph company has extended the connection from Bombay to Australia by way of Madras, to Penang in the Malay peninsula, and to the East Indian islands. In 1879 the Eastern telegraph company were engaged in laying their cable to the cape of Good Hope. An agreement was made by this company with the British government to have their line down between Durban and Zanzibar by the end of July, 1879, and to have the whole cable laid and in working order by the end of the year. In consideration of an annual subsidy of \$17,500, this company agreed to give priority to government messages, and to transmit them over the cable, which was to have a capacity of fourteen words per minute, at half the rate charged the public. The British government also stipulated for the right to take possession of the wires and offices, or to permit any of the colonies so to do, in the event of the occurrence of a war, rebellion, or any other public necessity, and to retain possession so long as this might be required, on the payment of a reasonable sum in compensation. The Cape cable is covered with a brass wrapping, to protect it against the ravages of the teredos and other injurious insects, except as to those portions laid in the deep-sea, where there is no danger from these annoyances. On Nov. 16 the American end of the new French cable, which was manufactured in the workshops of the Siemens Brothers in Charlton, England, was landed at North Eastham, Mass., on Cape Cod, from the steamer *Faraday*. This cable was constructed and submerged at a more rapid rate than any other ever known, the line being completed and messages sent from continent to continent seven months after the concession had been granted to the company by the French government. At about the same time a new cable was put down between Germany and Norway, this being done at the cost of the German government. Prior to that, the only telegraphic communication between Germany and Scandinavia was by way of Denmark. The new cable is a three-wired

line, extending from Romöe, an island off the coast of Sleswick, to a point near Arendal. The effect of this enterprise is to throw all telegraphic traffic between Germany and Norway, and the greater part of that with other countries, except Denmark, England, and France, over the new wires, withdrawing it from the Danish lines; this cable was made by Siemens & Halskæ of Berlin. A short cable was laid by Russia across the Caspian sea from cape Gurgian to Krasnovodsk, a distance of 150 miles. This made telegraphic connection between Tjikislar and Asterabad, and messages can be sent, by way of Teheran, by the Indo-European line to Tiflis. The final link in the chain of telegraphic communication around the earth is the projected cable between California and the Sandwich Islands, for which Cyrus W. Field received from the government of the latter country an exclusive concession, and is probably to be similarly favored by Japan and China. The latter two countries have long been ambitious of extending their telegraphic communication with the rest of the world. A recent scheme is for a new cable between America and Europe, to run from New York to Flores, an island of the Azores; two extensions from the latter terminus extending to the European continent, one being to France, England, and Holland; the other to Fayal, San Miguel, and Lisbon. This gigantic scheme comprehends 7,200 m. of cable.—The employment of subterranean telegraph wires, which has gained much favor on the continent of Europe, has been specially extended in Germany. These were at first only used for short distances, but were found to work so well that they have been laid for considerable lengths, and have entirely answered their purpose. There are in England 10,000 m. of underground wire, but there they do not seem to have encountered the same success in their operation. Objections made to their use are that they cost three or four times as much as open-air wires; that their power to transmit currents is only one-third or one-fourth as great; that the rats and mice attack their gutta-percha envelope; and that they are injured by insects, and also by a species of fungus.

In England, however, this plan is adopted with wires passing through large cities. As a new method of insulation discovered by David Brooks, of Philadelphia, obviates the difficulties which interfere with the successful working of subterranean wires, it may be that they will be hereafter employed in the United States. In the new process of insulation the material employed is paraffine oil. The wires are first wrapped in cotton, and then as many as fifty or more of them are bound together in a tight cover of netting, the whole being then inclosed in a pipe. The pipe, when laid under-ground, is kept continually filled with the oil under pressure, being supplied from connecting reservoirs. Since 1877 there have been short lines in successful operation on this plan; one of them being laid in 35 ft. of water under the Schuylkill river. A similar line is to be laid between Philadelphia and New York, when the process will have a more decisive test.—The difficulties involved in establishing telegraph lines between distant parts of the world are, perhaps, best shown in the case of the line between England and Australia. The line now runs from London to Gibraltar, thence to Malta; and from Malta to Alexandria by three lengths under the sea. Thence it crosses the isthmus of Suez to the latter point; and by another length of cable from Aden to Bombay. Here the Australian message takes to the land again, and crosses India by the government lines to Madras, where it is once more transferred to a submarine cable and carried to Singapore, touching at Penang. The messages for China now diverge, and are taken northward to Hong-Kong, Amoy, or Shanghai; while those for Australia are transmitted by cable to Batavia and Java, where they are taken along the Dutch lines to Banjoewangee, and thence by cable to Port Darwin, Australia. Land lines connect with Brisbane, Sydney, Melbourne, Adelaide, Hobart Town, and other Australian cities.—The postal telegraph system, as in existence in Great Britain, has attracted considerable attention in the United States, and it may be considered to be under advisement among those interested to effect an arrangement by which the entire telegraph system of that country shall be placed in the hands of the government.

TELEMACHUS, son of Odysseus (see **ULYSSES**) and Penelope (q. v.), was an infant when his father left home to join in the war against Troy, but during the latter's long absence of about 20 years, grew into manhood. At the instigation and under the guidance of Athene (Minerva), who had assumed the appearance of *Mentès* (commonly known as Mentor, Lat. "the thoughtful one"), king of the Taphians, his father's dearest friend, Telemachus set out in search of his long-lost sire, after having vainly endeavored to eject his mother's troublesome suitors from the house. Having visited Pylos and Sparta, at both of which places he was most hospitably entertained, Telemachus returned home to Ithaca, where he found his father in the guise of a beggar, living with the swineherd Eumæus. After mutual recognition, father and son proceeded to slay the suitors.—In modern times, Telemachus is known chiefly as the hero of Fénelon's (q. v.) romance, *Télémaque*, once very popular as a school-book.

TELEOLOGY, the doctrine of ends, is derived from the Greek *telos*, an end, a word brought into philosophic discussion by Aristotle. The idea of an end entered into the Aristotelian conception of physical science, but more properly into ethical science or morality. All the ancient systems of morality, from Socrates downward, correctly regarded it as a *practical* science; they started with the inquiry, "What is the proper and final end of all human conduct?" and the answer given by each school was the characteristic doctrine of the school. Aristotle answered, "Happiness in a peculiar sense;" the Stoics said, "A regard to the whole universe of being;" the Epicureans, "Pleasure and the absence of pain." John Stuart Mill, in the concluding chapter of his *Logic*, entitled, "The Logic of Practice, or Art; including Morality and Polity," adopts the ancient point of view, and observes that there should be a science of ends, or a reasoned statement of the final purpose of all human action; for this science he suggests the name *teleology*, remarking that it corresponds to what the Germans call the practical reason. There would be comprehended under it, the art of living or happiness, taste or the beautiful, morality, and politics. See **CIVILIZATION**. The word *teleology* is applied to the argument from design in proof of the Deity. This is in keeping with Aristotle's employment of the word in physics. When a natural philosopher assigns the purpose or end of any natural arrangement, as the offensive or defensive weapons of an animal, he is said to give a teleological explanation.

TELEOSAURUS, a genus of fossil crocodilès, the remains of which occur in the oolitic rocks. They are found associated with marine fossils, and the peculiar modification of their skeleton seems to have specially fitted them for an aquatic life. Both surfaces of the vertebrae were slightly concave, the hind-legs were large and strong, and the anterior portion of the body gradually tapered into the long and slender jaws, giving the animal the aspect of the gavia of the Ganges, only the jaws were more attenuated, and the nasal aperture, instead of being oblique, opened vertically on the truncated end of the upper mandible. The jaws were armed with numerous equal and slender teeth, slightly recurved, and admirably adapted for the capture of fishes, with which the oolitic seas abounded. No less than twenty species have been described, and these present so many striking differences that they have been arranged under six subgenera.

TELEOSTEI, the order of bony fishes, corresponding very nearly with Cuvier's division of *osseous fishes*, and comprising nearly all the common fishes. The skeleton, instead of remaining throughout life nearly or quite cartilaginous, is nearly or completely ossified. The notochord is not persistent, as in the inferior orders; there is a well developed vertebral column, although it is sometimes more or less cartilaginous. The bodies of the vertebrae are *amphicelous* or concave at both ends, forming a double conical, or globular cavity which is filled with the cartilaginous or semi-gelatinous remains of the notochord, which confers great flexibility on the vertebral column. The ossification is not carried further, except in the bony pike, a ganoid. The skull is much complicated, being composed of a great number of distinct cranial bones, and a lower jaw, or mandible, is always present. The pectoral arch has a clavicle, and the paired fins, when present, are supported by rays. Those having soft rays are called *malacopterygii*; those having spinous rays are called *acanthopterygii*. Besides the paired fins there is a variable number of unpaired integumentary expansions known as median fins, which when fully developed consist of one, two, or three fins on the back, called dorsal fins, one at the posterior end, called the caudal fin, and one or two on the ventral surface, called anal fins. The spines of the caudal fin are set vertically, and not horizontally, as in *cetacea*, and in all the bony fishes the form is said to be homocercal, that is, consisting of two equal lobes, but this is not strictly true, as the tail is generally not quite symmetrical, although not so manifestly unsymmetrical as in the cartilaginous fishes, sharks, and rays. The median fins are always supported by joints upon a series of interspinous bones whose spines pass inward and are attached to the spinous processes of the vertebrae. The heart contains two chambers, an auricle and a ventricle, and the branchial artery has its base developed into a *bulbus arteriosus*, which, however, has no striated muscular fibers, is not rhythmically contractile, and is only separated from the ventricle by a single row of valves. The respiratory organs are in the form of free, pectinated, or tufted branchiae, situated in two branchial chambers, each of which communicates internally with the pharynx by a series of clefts, and opens externally by a single aperture or gill-slit, protected by a bony gill-cover, beneath which there is a branchiostegal membrane, supported upon branchiostegal rays. The branchiae are supported by a series of bony arches, usually five on each side (the anterior four only bearing gills), which are connected below with the hyoid bone, and above with the skull. The nasal sacs never communicate posteriorly with the pharynx. These fishes are generally covered with horny cycloid or ctenoid scales overlapping each other, and forming what is called an exoskeleton, but these scales are sometimes absent, or represented by plates of true bone, which are sometimes ganoid, that is composed of an inferior layer of true bone covered by a superior layer of polished enamel; and sometimes formed of shagreen-like bony spines. The stomach is capacious; pyloric caeca are present. An air-bladder may or may not be present, and may or may not communicate with the gullet. The subdivisions of the osseous fishes are numerous, and comprise a great number of families which cannot be enumerated here.

The suborder *malacopteri*, or soft-rayed division, always have an air, or swim-bladder, which communicates with the œsophagus by a duct which is regarded as homologous to the wind-pipe of air-breathing animals having lungs. The skin is sometimes naked, but is usually covered with cycloid scales, sometimes with ganoid plates. The *malacopteri* are divided into two groups, the *apoda* which have no ventral fins, and contain the eel (q.v.) including the *gymnotus* (q.v.); and the *abdominalia*, having ventral fins, containing the pikes (q.v.) of the *esocidae* (q.v.); the carp (q.v.), chub (q.v.), roach (q.v.), minnow (q.v.), of the family of *cyprinidae* (q.v.); the various species of salmon and trout (q.v.) of the *salmonidae* (q.v.).

The suborder *acanthini* have fins which are always supported by soft rays, while the ventral fins are either wanting, or if present, are under the throat, below or anterior to the pectoral fins, and supported by the pectoral arch. The swim-bladder is sometimes absent, but when present does not communicate, as in the preceding order, with the œsophagus by a duct. This suborder is also divided into two groups, by the presence or absence of ventral fins—*apoda* and *subbrachiata*. The most familiar example of the *apoda* is the sand-eel (*ammodytes*) see LAUNCE, *ante*. The *subbrachiata* contain the two important families, the *gobiidae* (q.v.), or cod family, comprising the cod (q.v.), haddock (q.v.), ling (q.v.), etc., and the *pleuronectidae* (q.v.), or flat fishes (q.v.), comprising the sole (q.v.), plaice (q.v.), halibut (q.v.), brill (q.v.), turbot (q.v.), etc.

The suborder *acanthopteri* have fins in which one or more of the first rays are unjointed, inflexible, and spiny, and as a rule the exoskeleton being composed of ctenoid scales. The ventral fins are generally beneath or in advance of the pectorals, and the duct of the air-bladder is always absent. This suborder is divided into *pharyngognathi* (q.v.) having the inferior pharyngeal bones ankylosed to form a single bone; and *acanthopteri veri*, characterized by always having spiny rays in the first dorsal fin, and usually in the first rays of the other fins, while the inferior laryngeal bones are never ankylosed into a single mass. This division is perhaps the most typical of the teleost fishes containing the *percide*, see PERCH, *ante*; the *mygilidae*, see MULLET, *ante*; the *scomberidae* (q.v.), see also MACKEREL, *ante*; the *gobiidae*, see GOBY, *ante*; the *blenniidae*, see BLENNY, *ante*; and the *lophiidae*, see ANGLER, *ante*. The *percide* is the

most important family, and distinguished by having ctenoid scales, teeth on the palate and vomer, as well as on the jaws, and having from five to seven branchiostegal rays.

The suborder *plectognathi* are characterized by having the maxillary and premaxillary bones immovably connected on each side of the jaw. The endoskeleton is only partially ossified, and the vertebral column remains permanently cartilaginous. The exoskeleton is in the form of ganoid plates, scales, or spines, and there are generally no ventral fins, and the air-bladder has no duct. The most remarkable fishes of this subdivision are the trunk fishes (q.v.). See also *OSTRACION*, *ante*.

The suborder *lophobranchii* (q.v.) is a small group, characterized by a peculiar structure of the gills, which are arranged in little tufts upon the branchial arches instead of in comb-like plates, as in the typical bony fishes. The endoskeleton is only partially bony, but the exoskeleton is composed of ganoid plates, and the air-bladder has no duct. Belonging to this suborder are the sea-horses or *hippocampidae*, see *HIPPOCAMPUS*, *ante*; and the *syngnathidae*, see *PIPE-FISH*, *ante*.

TELEPHONE. This instrument is designed to convey sounds to a distance by means of electricity. In 1860 Reis of Frankfort first recognized the principle of the telephone, using a membrane which, vibrating under the action of sound, caused pulsations of electricity to pass along the wire, and actuated the armature of an electro-magnet, which, mounted on a sounding-board reproduced a sound corresponding in pitch and rhythm with the original. The quality of the sound was however entirely lost. There are several claimants for priority in the discovery of the principle of the articulating telephone, and the discoveries of Gray of Chicago, and Graham Bell, an Edinburgh gentleman resident in America, appear to have been nearly contemporaneous, and attained by different lines of study. The articulating telephone of Bell, which was first shown at the Philadelphia Centennial exhibition, is now of very simple construction. A small bar magnet, with a coil of wire over one end, is placed close behind a diaphragm of ferro-type, the whole being inclosed in a case furnished with a mouthpiece. Words spoken into the telephone are reproduced faithfully on a similar instrument at great distances, and by use of the microphone (q.v.) the most minute sounds have been distinctly heard and even magnified. Many extraordinary results have been achieved in conveying and reproducing sounds, and self-caught sounds from "induction" in the wires have produced interesting results. While the telephone is already very largely used in America for domestic and business communication, it has been less successful in Britain, the busier lines increasing the difficulties of induction. Three requirements appear to be demanded to bring the telephone into general use, namely, a simple and reliable call or *avertisseur*, an increase of the sound to render it unnecessary to hold the telephone to the ear, and the removal of induction currents. Various methods for accomplishing each of these ends are now (1879) proposed, but the difficulties are not yet wholly overcome. A controversy exists whether the sounds in the receiving telephone are vibratory or molecular, or a combination of both.

TELEPHORUS, a genus of coleopterous insects, of the suborder *pentamera*, and section *sericornes*. The body is long, narrow, depressed, soft, and somewhat flexible. The species are numerous, and some of them abound in Britain in summer, chiefly in meadows and pastures. The larvae dwell in moist earth, and devour small insects and their larvae. The perfect insect feeds on similar food.

TELERPETON, a remarkable genus of fossil reptiles, the relics of which have been found in fine-grained whitish sandstone quarried at Cummington, near Elgin. A single species, or rather a single specimen, is all that as yet has been detected. It exhibits the skeleton complete, with the exception of the termination of the tail, but the bones have disappeared, and left only the casts as dark-colored cavities in the pale gray rock. Nearly perfect casts of their form were taken by Dr. G. Mantell from these hollow casts. The impressions are so well defined as clearly to show that there were twenty-six vertebrae between the skull and the sacrum, two sacral vertebrae, and a portion of the tail preserved on the slab consists of thirteen others. The ribs, of which there are twenty-one pair, are very slender; they are short near the head, but quickly lengthen as they leave it. The reptilian nature of this fossil is evident. By Dr. Mantell it was considered to be a batrachian, and described as *telorpeton Elginense*; but prof. Owen has more correctly referred it to the lacertine type, because of the numerous ribs, the structure of the sacrum, and the form of the pelvis. He has named it *leptopleuron lacertium*. It has been matter of debate whether the rocks in which the telorpeton was found belong to the old red sandstone measures or to the trias.

TELESCOPE (Gr. *têlêskopos*, far seeing) consists essentially of a lens or mirror, to form, within our reach, an image of a distant object; and a microscope (q.v.), to examine this image in detail. Its invention is ascribed to various individuals living about the end of the 16th c.; but there is no doubt that Galilei (q.v.) was the first to apply it to any purpose other than the gratification of mere curiosity.

The space at our disposal will not allow of our entering into any minute details, so we propose to give: *first*, a general idea of the mode in which a telescope acts, in the course of which we shall incidentally show how the magnifying power and the brightness of the image depend on the dimensions of the various parts of the instrument; *second*, to point out the various causes of imperfection, which in all telescopes are

unavoidable, and how these are reduced to as small an amount as possible; *third*, to mention the most important of the many forms which have been devised, and the processes by which these delicate instruments are practically constructed.

When a lens is employed, as in a camera obscura, to form an image of an object, as AB in fig. 1, the distance of the image from the lens depends on the focal length of

FIG. 1.

the lens, and also on the distance of the object. Practically, with telescopes, the distance of the image from the lens is, on account of the remoteness of the object, the focal length of the lens. Also the image of any point, A , of the object lies in the prolongation of the line joining A with the center, C , of the lens. Join AC , and produce it to a , Ca being made equal to the focal length of the lens, a is the point at which the image

FIG. 2.

of A is formed. Similarly at b the image of B is formed. Thus the image is *inverted*; and, seen from C , the image and the object subtend equal angles, or look equally large. When a concave mirror forms an image, the effect is as in fig. 2, where C is now the center of the sphere of which the mirror is a portion. When the object, AB , is at a great distance, the image, ab , is *inverted*, and is formed half way between C and the mirror. As before, object and image subtend equal angles at C . In order to see these images, the eye must be placed at some such point as E in each of the figures.

So much for the formation *within our reach* of an image of a distant body. We must next show the action of a lens when employed to magnify this image. When an object, as ab in fig. 3, is placed rather nearer to a lens than its focal length, rays which pass from the object through the lens appear to have come, not from the object, but from an enlarged image as $\alpha\beta$, at a greater distance from the lens—but subtending, as before, the same angle at the center, c , of the lens. In practice, the lens is so adjusted as to form the image, $\alpha\beta$, at a distance of about 10 in. from c , in which case the eye sees it most distinctly, and the distance of ab from the lens is then (practically) the focal length of the lens.

FIG. 3.

We now combine the first and third diagrams, and we have the *common astronomical telescope*. The magnifying power is obviously to be measured by the increase in the angle which is subtended by the image $\alpha\beta$ (fig. 4), over that which is subtended by the object, AB . The angle at C is the measure of the apparent size of the object; that at c , of the apparent size of the image. And it is easy to see from the quadrilateral $Cacb$ in the figure that these angles are inversely as the sides Ca and ac . (For instance, if Ca have six times the length of ac , the angle at C will be only one-sixth of that at c .) Hence the magnifying power is to be found by dividing the focal length of the object-lens by that of the eye-lens. In practice, the lenses are so mounted in tubes that their distance may be increased or diminished at pleasure. When the object, AB , comes nearer the observer, its image, ab , is formed *further* from the lens C . Hence, for near objects, the telescope requires

FIG. 4.

to be pulled out. Again, the distance of most distinct vision differs for different people, so that even when AB is at a fixed distance, short-sighted and long-sighted eyes require the eye-lens to be removed from, or advanced to, ab , so that for each eye $\alpha\beta$ may be formed at the distance at which it can be most distinctly seen.

To estimate the relative brightness of the image and object, suppose, for simplicity, all the light which enters the telescope from the object to reach the eye. Then the quantity of light which enters the eye from the image is greater than that which would enter the unaided eye from the object, in the ratio of the aperture of the object-glass, C, to the aperture of the pupil of the eye. But it is spread over a magnified image. If the image be as much larger than the object as the object-glass is larger than the pupil of the eye, the object and image will appear equally bright. Taking the aperture of the pupil as $\frac{1}{10}$ in., the object-lens would require an aperture of 10 in., with a magnifying power of 100 times, in order that brightness should not be lost. Practically, the most formidable difficulty in attaining very high magnifying powers is that due to the enormous size of lenses and mirrors which are required to give the necessary brightness to the enlarged image. It is easy to see that it is impossible to render the final image brighter than the object by any increase of dimensions in the object-lens.

After what we have said about the common astronomical telescope, the reader will have no difficulty, from a combination of figures 2 and 3, in understanding the construction of the Newtonian or Herschelian reflecting telescope.

We proceed to the second part of our proposed scheme of treatment of the subject, viz., the unavoidable imperfections of the telescope, and their reduction to a minimum.

In the first place, then, even with a mirror—where we are not annoyed by the breaking up of white light into its component colors, since the law of reflection (q.v.) is the same for all rays—it is impossible to form a perfectly sharp image of more than one definite point at a time. In order to do even this, the mirror must be formed as part of the prolate spheroid produced by the rotation, about its longer axis, of an ellipse (q.v.), one of whose foci is the object-point, the other the image. If the object-point be, like a star, practically at an infinite distance, the requisite form of the mirror is that formed by the rotation of a parabola (q.v.) about its axis. The axis of the mirror must then be directed to the object-point, and all rays from it will, after reflection, pass accurately through the focus. But this is not strictly true for any other object-point in the field of view, although so nearly true that no inconvenience is practically found to result from it. But, if the mirror used be part of a sphere, no point can be found such that rays diverging from it shall all be brought after reflection accurately to one point of the image; and this defect, called *spherical aberration*, increases proportionally to the surface of the mirror; so that by increasing that surface, for the attainment of brightness, we increase proportionally the indistinctness of the image. To give an idea of the delicate manipulation required in the construction of a reflecting telescope, we take the case of a speculum of 4 ft. aperture and 40 ft. focus, as calculated by sir J. Herschel. If this be first ground to a truly spherical form, it must have a radius of 80 ft., as we have seen above. Now, such a mirror will give a very indistinct image, even under the most favorable circumstances; yet to grind it to the parabolic form, which is practically perfect, leaving the middle untouched, and grinding more and more away from its surface as we proceed outward to the edges, even at the edges we have to remove a film of metal of only the $\frac{1}{11333}$ part of an inch, somewhere about the $\frac{1}{100}$ part of the thickness of the paper on which this is printed!

Lenses, whether the object-lens or the eye-lens, have this defect also; but, as a rule, the spherical aberration in lenses is almost negligible compared with *chromatic aberration*, which arises from the different refrangibilities (see REFRACTION) of the various colored rays; and leads to the formation, by a lens, of a separate image of a bright object for each colored ray. The remedy consists in *achromatizing* (see ACHROMATIC, REFRACTION) the lens—i.e., forming it of two or more lenses of different kinds of glass—so that the colors, separated by one, shall be reunited by the others. With a double achromatic lens, in which a convex lens of crown glass is united to a concave of flint-glass, the focal lengths of the separate lenses can be easily adjusted so as to bring, when in combination, any two assigned rays of the spectrum (q.v.) simultaneously to a focus; and, by a judicious selection of these two rays, we may reduce the consequences of irrationality of dispersion (See REFRACTION) to a minimum. But this is not all. To construct a lens of a given material which shall have a given focal length, is an *indeterminate* problem; we may assign the curvature of either surface at pleasure, and then that of the other is definite, and can be calculated. Thus, the achromatism of a double-lens can be secured in an infinite variety of ways, and we may impose further conditions; i.e., that the curvatures of the convex and concave surfaces shall be adjusted so as to destroy to as far as possible the spherical aberration. Other imperfections, such as those due to (q.v.), etc., cannot be here more than alluded to, as they do not admit, within any reasonable limits, of being popularly explained. Nor can we enter upon questions connected with the correction of chromatic and spherical aberrations in eye-pieces, which is effected by the combination of two or more lenses (generally of the same material) placed at a certain distance from each other. We may only mention that the defect (for terrestrial purposes) of the common astronomical telescope, the inversion of the image, is overcome by combining two such telescopes, the smaller to examine the image formed by the larger, and therefore to reinvert it. This practically comes to constructing the eye-piece of three lenses at a distance from each other; though, for greater distinctness, four are usually employed.

In the earliest, or Galilean, telescope, the eye-lens is concave; a construction only

now used in opera-glasses. It has far less chromatic and spherical aberration than the common astronomical telescope, and is shorter, since the distance between the lenses is the *difference*, not the *sum* of their focal lengths; but it has a very serious defect in the smallness of its field of view. This can only be enlarged, as in opera-glasses, by making the diameter of the object-lens disproportionately great.

Before the discovery of the possibility of forming an achromatic lens, Huygens, Cassini, and others, had endeavored, by enormously increasing the focal length of the object-glass of the common astronomical telescope in proportion to its diameter, to get rid as far as possible of chromatic aberration. This was called the *airial* telescope, as the object and eye-lenses were mounted separately on stands; the tube (which would have been 100 200, or even 600 ft. long) being dispensed with. Valuable work was done with some of these telescopes, of 125 ft. focus, but the longer ones proved unmanageable. The principle involved in these constructions is, practically, the throwing the magnifying power more on the object-lens than on the eye-lens; as the image formed by the former was still so imperfect as not to bear much additional magnification; although achromatic eye-pieces could even then be made with one kind of glass. The great step required for shortening the unwieldy instrument was therefore the perfecting of the object-lens. We have already seen how this was effected. Various very ingenious improvements on achromatic combinations, even yet (we should be inclined to think) worthy the consideration of opticians, were devised by Dr. Blair. He obtained in solutions of mercury or antimony in hydrochloric acid, media, in which, while much more refractive and more dispersive than crown-glass, no irrationality of dispersion as compared with crown-glass could be detected. With these fluid lenses he was enabled to give the telescope an aperture of $\frac{1}{2}$ of its focal length without a trace of residual color. The *diatlytic* telescope, invented in 1828 by Mr. Rodger, and since made by Plössl, seems to promise very well. Its object is to obtain a large aperture for the telescope with a flint-lens (the obtaining of which, in large and perfect disks, is the great difficulty) of moderate size. In this telescope the object-lens is single, and of crown-glass; having, of course, all the defects of the single lens. These are corrected, at some distance in the cone of converging rays, by the interposition of a combination of a pair of much smaller lenses, whose focal lengths are equal for red rays; the first being a convex lens of crown, the second a concave of flint glass. The adjustments of this instrument for exact correction are, a motion of the pair of lenses to or from the object-lens, to correct chromatic aberration; and a change of the distance between the two smaller lenses, to correct spherical aberration.

Chromatic being so much more serious than spherical aberration, it is not to be wondered at that the idea of substituting an object-mirror, in which the former is absent, for an object-lens, was early suggested. The first practicable scheme for the purpose seems to have been that of Gregory; in which, however, two mirrors are employed. In the skillful hands of Short, this instrument completely superseded the ordinary astronomical telescope. Its chief defects are, the great loss of light by two direct reflections, and the increase of the spherical aberration by the fact that both mirrors are concave. The first defect is incurable, the second was partially overcome by Cassegrain's plan of using a small *convex* mirror for the second reflection. To Newton is due the simple idea of using the combination of a single curved mirror with a plane mirror and an eye-piece; a construction differing only in slight particulars from that now universally adopted for reflecting instruments. Newton constructed several such telescopes with his own hands, some of which are still preserved, as in the apartments of the royal society at Burlington House.

The elder Herschel constructed for himself all the instruments, gradually increasing in magnitude the optical power, by means of which he made his grand discoveries; and his son worthily succeeded him, both as constructor and observer.

The gigantic telescopes of lord Rosse and Mr. Lassell are wonderful examples of delicate art, and have had their full share, with the large achromatics of the present day, in the startling discoveries of modern astronomy.

The process of Liebig for depositing on glass an exceedingly thin film of silver, which, by careful polishing, can be rendered more highly reflective than any other material, has been taken advantage of by Steinheil in the construction of large specula. This is an immense step, since any disk of glass will do, its optical properties not being employed; while, if it be once brought to a true parabolic figure, the silvering may be renewed as often as may be required. One of the great difficulties in the construction and working of large reflectors has hitherto been the casting and annealing of metallic masses of a few tons' weight. This, in the silvered specula, is entirely avoided. We cannot here enter into a description of the processes, often extremely ingenious, which have been devised for the grinding, figuring, and polishing of lenses and specula. The reader who desires strictly scientific information, conveyed in a thoroughly popular form, on this and all other points connected with the subject, is referred to sir John Herschel's article "Telescope," in the *Encyclopædia Britannica*, to which we have been largely indebted, and which has been reprinted in a separate form.

TELFAIR, a co. in s. Georgia, drained and bounded by the Ocmulgee and Little Ocmulgee rivers; traversed by the Macon and Brunswick railroad; 925 sq. m.; pop.

'80, 4,828—4,816 of American birth; 2,163 colored. The soil is sandy and covered with pine forests; corn, sweet potatoes, and cotton are the staples. Co. seat, Jacksonville.

TELFORD, THOMAS, an eminent engineer, was b. in the parish of Wester Kirk, in Eskdale, Dumfriesshire, Aug. 9, 1757. His father was a shepherd; and during the intervals of his attendance at school, young Telford followed the same occupation, diligently employing his leisure moments in the perusal of whatever books were within his reach. At the age of 14, he adopted the trade of a stone-mason; and long years afterward, when he had attained the summit of his profession, he confessed the advantages which he derived during this period from "the necessity of making himself acquainted with every detail in the procuring, preparing, and employing of every kind of material, whether it be the produce of the forest, the quarry, or the forge." In 1780 he removed to Edinburgh, and in 1783, he repaired to London, obtaining employment under sir William Chambers, who was then engaged on his chief work, the erection of Somerset house. Telford's merits attracted the notice of his employer, and he was appointed in 1784 to superintend the erection of the resident commissioner's house at Portsmouth dockyard, a work which lasted over three years, and afforded Telford the opportunity, of which he fully availed himself, of mastering the details of construction of docks, wharf-walls, etc. In 1787, he was appointed surveyor of public works for Shropshire; and his two bridges over the Severn at Montford ($3\frac{1}{2}$ m. w.n.w. of Shrewsbury) and Buildwas ($1\frac{1}{2}$ m. w. of Coalbrook Dale), a large number of minor bridges, and other county works, testified to the genius and industry of the rising engineer, and gained for him the planning and superintendence of the projected Ellesmere canal, 103 m. in length, to connect the navigation of the Severn, Dec, and Mersey—a work which occupied 10 years (1795–1805), and greatly added to the already eminent reputation of Telford. In 1790 he was appointed by the British fishery society to inspect the harbors at their various stations, and in 1801 he received a commission from government to report on the state of Scotland, and on the desirable public works for that country. As a consequence, the plan of a canal from Inverness to Fort-William was revived, and its planning and construction intrusted to Telford (see CALEDONIAN CANAL). In the same capacity of engineer to the parliamentary commission of roads and bridges for Scotland, he executed more than 1000 m. of road in the Highlands, Lanarkshire, and Dumfriesshire (see ROAD-MAKING), and erected about 1200 bridges, besides churches, manse, harbors, etc. In 1808, and again in 1813, he was invited to Sweden, to report on the projected scheme for connecting lake Wener with the Baltic, and superintended the construction of the Gotha canal, by which this was effected; receiving on his departure numerous and valuable marks of the royal approbation. His next great work was the construction of the road from London to Holyhead, including the erection of numerous bridges—among others, of the Menai suspension bridge (q.v.)—and the last was the execution of the St. Katharine's docks in London, a work of remarkable merit. His other works are far too many to enumerate. We can only afford to state that, of bridges, the Conway (q.v.), the Broomielaw at Glasgow, the Dean in Edinburgh, the Over at Gloucester (an innovation on the ordinary form); of canals, the Glasgow and Paisley, the Macclesfield, the Birmingham and Liverpool junction, the Gloucester and Berkeley, the Weaver system, the great tunnel ($1\frac{1}{2}$ m. long) on the Trent and Mersey; of harbors, Peterhead, Banff, Fraserburgh, Fortrose, Culleu, and Kirkwall—were planned by this indefatigable genius, and wholly or partially erected under his superintendence. He was much employed by parliament to report on all public engineering schemes or works of importance, and was also occasionally consulted by the Russian government. For the last few years of his life, he retired from the active duties of his profession, employed himself in collecting and arranging materials for a complete history of his various works, and had the greater portion of the MSS. ready when he was seized with a severe bilious attack, and died at Abingdon street, Westminster, Sept. 2, 1834. His life, entitled *The Life of Thomas Telford, Civil Engineer, written by himself*, was published in 1838, in 1 vol. 4to, accompanied with a companion volume of plates. While a mason in Dumfriesshire, he was known favorably as a writer of short poems, in the homely dialect of his district, which are to be found in the appendix to his autobiography. He completed his imperfect school education during the intervals of business, becoming an excellent linguist, and contributed to the *Edinburgh Encyclopædia*. He was elected a member of the Royal society of Edinburgh in 1803, and of its more eminent southern sister in 1827.

TELL, a district in the extreme n.w. of Africa, stretches along the shores of the Mediterranean, and comprehends the corn-growing tracts extending s. from the Mediterranean to the Atlas mountains, and from w. to e. through Morocco, Algeria, and Tunis. The Tell is noticed under the articles Africa and Sahara (q.v.).

TELL, WILLIAM, was, according to Swiss tradition, a patriot who, in the 14th c., rescued his native district from the tyranny of the house of Austria. His story has been variously told, but that version which has found the widest currency is the following. In the beginning of the 14th c., Albert I. of Austria was striving to annex the three Waldstädte, Uri, Schwyz, and Unterwalden, to his family estates. Hermann Gessler, his bailiff (or *Landvogt*), lived at the castle of Küssnacht, and perpetrated on the people of the district the most atrocious cruelties. A league was formed of the principal men of the Waldstädte to resist the Austrian pretensions, and to it belonged Walter Fürst, and William

Tell, his son-in-law. Among other acts of tyranny, Gessler placed the ducal hat of Austria on the top of a long pole, erected in the market-place of Altorf, and gave orders that no one should pass without uncovering his head. Tell and his little boy one day took no notice of the hat, and were at once dragged before Gessler. He, hearing that Tell enjoyed great reputation as a cross-bowman, resolved to make his skill a means of punishing him. He was ordered to shoot an apple from his son's head, and told that if he missed it, he should die. To the amazement of all present, he hit the apple without injuring the child. But this did not satisfy Gessler. Turning to Tell, he asked him what he meant to have done with a second arrow he had in his girdle. "To have shot you if it had slain my son," was the reply. Tell was then seized, bound, and thrown into a boat on the lake of Lucerne, to be taken with Gessler and his men to the castle of Küssnacht. A sudden Alpine storm sprung up. Tell was the only man on board who knew the shore, and could manage a boat in such weather. He was allowed to take the helm, and he soon ran her toward a rocky ledge; he there seized his bow and arrows, sprang on shore, and pushed the vessel back into the water. The storm, however, abated, and Gessler and his party landed. Tell lay in wait for them in a rocky defile, and as they passed, he shot Gessler through the heart. This befell in 1307, and was followed by the great Swiss war with Austria—the first of a series which lasted till 1499—in which, however, Tell took no prominent part. Tell was drowned, it is added, in 1350, in attempting to save a friend during a great flood of the river Schächen.

There is evidence that, in 1387, a religious service was instituted to commemorate the act of Tell at the place where he lived; and that, in the following year, Tell's chapel was built on the spot where the boat was said to have landed. Russ and Etterlin, chroniclers who lived toward the end of the 15th c., told his story as true history. Tschudi, who wrote in the first part of the 16th c., repeated it in the form in which it is now familiar to us, and in which it was adopted by Schiller, in his well-known drama. So early as the end of the 16th c., however, doubts were expressed of its authenticity. Guilmann, who wrote a book, *De Rebus Helveticis*, called in question the very existence of Tell. What, he asks, has become of his family and relatives? Why was he not spoken of by his contemporaries? Grasser, the author of a Swiss *Heldenbuch*, pointed out a striking resemblance between Tell and Toke, the hero of an old Scandinavian fable, recorded by Saxo Grammaticus. From that period, incredulity became general, and several books were published to show that the story was legendary. One of these, *Guillaume Tell; fable danoise*, was burned by the public hangman at Uri, and then a patriotic feeling was manifested on the subject, which, it is believed, made Swiss writers, including J. von Müller the historian, cautious in expressing farther doubt. Voltaire, in speaking of Tell, makes the remark, that "*l'histoire de la pomme est bien suspecte*," and asserts that no part of the tale had a foundation in fact. His opinion became known all over Europe; and since then, a whole library has been published on the story of Tell, in Switzerland, Germany, Denmark, and France. The most important works, however, bearing on the question, are (1) Ideler's work, *Die Sage vom Scheusse des Tell*, published at Berlin in 1826, in which it is shown that the incident of the apple is purely legendary; (2) an edition of Russ's chronicle, edited in 1834, by M. Schneller of Lucerne, in which it is proved that serious disparities exist between the different versions of the story as told by the Swiss chroniclers; and (3) a work containing a series of documents relating to early Swiss history, published in 1835 by M. Kopp, also of Lucerne, in which it is as satisfactorily shown that, although a continuous series of charters exist relative to the bailiffs of Küssnacht in the 14th c., there is no Gessler among them. Tell is nowhere mentioned in contemporary records; but it need not, therefore, be inferred that an obscure peasant did not exist of the name, who shot an Austrian bailiff on the banks of the lake of Lucerne, who by this act caused a revolt, and who lost his life in attempting to save that of a friend. If such incidents really occurred—and from the early foundation of Tell's chapel, and other facts connected with it, we must presume they did—it would be easy to explain how they became connected with the old fable of the tyrant, the bowman, and the apple.—Ample information on the Tell controversy will be found in Hisely's *Recherches* (1843); and Vischer's *Die Sage von der Befreiung der Waldstätte* (1867).

TELLEZ, GABRIEL, better known by his literary pseudonym of *Tirso de Molina*, a Spanish dramatist of great reputation, was b. at Madrid in 1585, became a monk in 1620, and died in 1648, prior of the order to which he belonged. Tellez was a friend and pupil of Lope de Vega, whom he almost rivaled in facility of execution. In the preface to his *Cigarrales de Toledo* (1621), a collection of novels and comedies, he reckons the number of the latter composed by him at 300; of which, however, only 68 have come down to us. Besides these, he wrote several interludes, a great number of *Autos Sierumentales*, an *Acto de Contricion en Verso*, and a *Genealogia de los Condes de Sastago* (Mad. 1640). Tellez ranks next to Calderon and Lope de Vega as a dramatist. Although he generously affected to consider himself only a follower of the latter, he is really one of the most decisively original geniuses of his country, and imitated Lope in nothing except in cultivating the same national spirit in literature. His plays, deficient in artistic conception, are full of dramatic vitality. The "situations" are numerous and captivating, the delineation of character fresh, piquant and vigorous; the wit abundant,

and the language richly poetical.—The best edition of Tellez's works is that of Don Juan Eugenio Hartzenbusch, in the *Teatro Escogido* (12 vols., Madrid, 1839-42).

TELLICHERY, a sea-port t. and military station of British India, in the district of Malabar, 90 m. s.w. of Seringapatam. The site of the town is very beautiful, and the neighboring country highly productive, the low lands producing two, and in some cases three, crops of rice in the year. The cocoa-nut tree also grows in great abundance, and is put to many uses by the inhabitants. On account of its salubrity, Tellicherry has been called the Montpellier of India. There is a natural breakwater abreast of the fort, formed by a reef of rocks running parallel to the shore, having a depth within suitable for ships of 500 or 600 tons. Pop. '71, 20,504.

TELLING FORTUNES is a criminal offense when accompanied with begging of money or with fraudulent objects. Every person going about pretending or professing to tell fortunes, or using any subtle craft, means, or device, by palmistry or otherwise, to deceive and impose on her majesty's subjects, is deemed in law a rogue and vagabond, and may be committed to the house of correction for three months, with hard labor, by a justice of the peace.

TELLINIDÆ, a family of lamellibranchiate mollusks; having the mantle widely open in front; the foot tongue-shaped; the siphons separate, long, and slender; the shell usually equivalve and shutting close, the hinge toothed. The species are very numerous, and are found in almost all seas, mostly living in sand or sandy mud, some of them at a considerable depth. The fossil species are also numerous, and are found in the more recent formations. The genus *donax* belongs to this family.

TELLURIUM (symb. *Te*, equiv. 64—new system, 128—spec. grav. 6.183) is a chemical element, which some authorities place among the metals, and others among the non-metallic bodies or metalloids. Although in its outward characters it closely resembles the metals, its close analogies with sulphur and selenium indicate that its true place is among the metalloids. It possesses a high metallic luster, and resembles bismuth in color; it fuses at about 850°, and at a higher temperature is converted into a yellow vapor; it is a bad conductor of heat and electricity. When strongly heated in the air it burns with a blue flame, and gives off white fumes of tellurous acid. Like sulphur and selenium, it is soluble in cold oil of vitriol, to which it gives a fine purple-red color, and on dilution it is precipitated unchanged; and in these respects differs from all metals. In nitric acid it dissolves with oxidation.

Tellurium forms two compounds with oxygen, viz., *tellurous acid*, TeO_2 , and *telluric acid*, TeO_3 . *Tellurous acid* exhibits very slight acid properties, and in the anhydrous state it combines with acids, and acts the part of a weak base. These salts have a metallic taste, and are said to act powerfully as emetics. The *telluric acid* has only a feeble affinity for bases, but it forms salts, which contain 1, 2, and 4 atoms of the acid to each atom of base. Tellurium unites with hydrogen to form tellureted hydrogen, TeH , which is a gaseous body, analogous to sulphureted hydrogen, and precipitates most of the metals from their solutions in the form of tellurides, which have a close analogy with the corresponding sulphides.

In experimenting upon the action of the salts of tellurium, it has been found that they possess the power of forming, in the body of a healthy person, compounds which impart to the breath, to the perspiration, and to the gases generated in the intestinal canal, a disgusting fetor, which makes him a nuisance to every one he approaches; and this smell may last for weeks, although the quantity of tellurium that was administered did not exceed a quarter of a grain.

Tellurium is a rare substance, found chiefly in Transylvania, but recently discovered in Hungary, in North America, and in the Altaï silver mines. It sometimes occurs native, but more commonly as a telluride of gold, lead, or silver. For the method of extracting it, we must refer to any of the larger works on chemistry, and especially to the *Lehrbuch* of Berzelius. It was discovered in 1782 by Müller von Reichenstein, but it was not till 1798 that its properties were accurately studied by Klaproth. The word tellurium is derived from the Latin *tellus*, the earth.

TEMBU (Abatembu, or Tambookie) is the name of an important tribe of Kaffirs, occupying the region e. of the present boundary of the Cape Colony, where it forms the eastern limit of the district of Queenstown, formed by sir Harry Smith in 1849-50, a rather elevated plateau, from which flow the head-waters of the Kei, Bashee, Tsomo, and other important rivers. They number about 90,000 souls, and are of a less warlike and predatory nature than the adjoining tribes of the Amaxosa and Amagaleka Kaffirs. In the earlier Kafir wars, and even in the great one of 1835-36, the Tambookie Kaffirs remained neutral, and even friendly to the colonists; but in the war of 1848-49, they were induced to join the other tribes, and were defeated with great loss by a small colonial force. In the war of 1851 they were much broken and scattered; but eventually submitting to the British authority, they have quietly located themselves in the unoccupied country e. of the White Kei and Tsomo rivers, a good pastoral region, but rather bare of wood. Wesleyan missionaries have several stations among the Tambookie tribe, and many of them exhibit very pleasing features. A British resident, paid by the Cape Colony, also resides among them.

TEMES, a co. in s.e. Hungary, in the trans-Tibiscan circle; 2,289 sq.m.; pop. '70, 356,174. It is drained by the Temes and Bega rivers. The soil is very fertile, producing wheat, corn, hemp, flax, fruit, cotton, and grapes from which much wine is made. The silk-worm is raised, and great numbers of cattle. Capital, Temesvár.

TEMESVÁR, a Hungarian city, seat of the commander of the Banatish-Servian military frontier, is a strongly fortified place on the Bega canal, and is about 300 m. s.e. of Vienna, with which it is connected by railway. The town is fortified with a triple wall and moat, and has four suburbs. Of the population about a half are German, only a seventh being Magyar, and the rest Rumanians, Jews, and Servians. In Temesvár are a fine cathedral, an ancient castle, a magnificent episcopal residence, an armory, barracks, and a theater. There are manufactures of cloth, silk, paper, and oil, and a brisk transit trade in grain, wax, honey, and brandy, with Transylvania, Servia, and Rumania. Temesvár has endured a vast number of sieges—the latest being that of 1849, when it was bombarded for 107 days by the Hungarian insurgents, but was relieved at the end of that time by marshal Haynau. Pop. '69, 32,223.

TEMISCOUATA, a co. in e. Quebec, Canada, bordered n.w. by the St. Lawrence river, and s. by New Brunswick and Maine; 1770 sq.m.; pop. '70, 22,491. The surface is mountainous. Co. seat, Isle Vert.

TEMPÉ, a narrow valley or gorge, about 4½ m. long, in the n.e. of Thessaly, between Olympus (q.v.) and Ossa (q.v.), through which flows the river Peneus. The classic poets (none of whom, curious to say, appear to have ever seen the glen) praise it for its matchless beauty, and hence the name with them became a synonym for any lovely vale. In point of fact, however, the scenery of Tempé is characterized by wild grandeur rather than by soft sylvan charms.

TEMPERA, in painting, the same as *distemper* (q.v.).

TEMPERAMENT is a term which has been employed in physiology ever since the time of Galen, to designate the certain physical and mental characteristics presented by different individuals. Dr. Todd, in his article on this subject in the *Cyclopædia of Anatomy and Physiology*, observes that "the temperaments the existence of which seems most consistent with observation, are those admitted by Cullen, namely, the *sanguineous* and the *melancholic*, the *phlegmatic* being a degree or modification of the sanguineous, and the *choleric* of the melancholic.

Individuals of the *sanguineous* or *sanguine* temperament are such, according to Cullen, as have the quantity of fluids in the body large in proportion to the solids; the habit of body soft and plump; the skin smooth, white, and readily sweating on exercise; the hair soft, and generally pale, passing from thence to a red tint; the complexion ruddy; the eyes blue; the bodily strength moderate; and the mind sensible, irritable, cheerful, and unsteady. In persons of the *melancholic* temperament, the habit of the body is somewhat hard and meager; the skin and complexion coarse, and of a dun color; the hair hard, curly, and black; the strength considerable; the mind slow, disposed to gravity, caution, and timidity, but tenacious and steady.

Some writers recognize a *nervous* temperament, in which the predominating characteristic is a great excitability of the nervous system, and an undue predominance of the emotional impulses. This temperament is always associated with the sanguineous or the melancholic. In both sexes, the characteristics of the temperaments are far less manifest in old age than in earlier life. If it be admitted, as Dr. Todd believes, that a constant connection exists between color and temperament, it obviously follows that the nature of the temperament is determined by certain peculiarities in the physical condition of the organism. The different temperaments often merge so gradually into one another that it is in many cases difficult to decide positively to which variety any special case belongs.

TEMPERAMENT, in music, a system of compromise in keyed instruments for the avoidance of the necessity presupposed by the strict relation of musical intervals of having a separate row of keys corresponding to each tonic. Taking C as keynote, the ratios of the notes of the diatonic scale, as derived from the number of vibrations in a given time of a string sounding that note (see *MUSIC*), are:

C	D	E	F	G	A	B	C
24	27	30	32	36	40	45	48

The intervals between these notes are by no means equal, and may be thus expressed in numbers by logarithms:

C	D	E	F	G	A	B	C
51	46	28	51	46	51	28	

We have here three species of intervals, of which those represented by 51 are called major tones; those by 46, minor tones; and the smaller intervals represented by 28, semitones. These intervals will evidently only serve with C as keynote. If, for example, we start from D instead of C, we find E a tolerable, though not quite correct, second to D; but the third and seventh of the scale are entirely wrong. Were the major and minor

tones equal, and each semitone exactly half a tone, the insertion of a note in the middle of each tone dividing the seven intervals would make it immaterial where the scale began; any one of the twelve notes becoming alike available as a keynote; and though such equality is contrary to the immutable principles of harmony, an arrangement based on it is found practically to give but little offense to the ear. In what is called the *equal temperament*, the twelve intervals are all of the same length, and no advantage is given to one key over the rest. This is, in theory at least, the temperament adopted in the pianoforte. Another system, known in this country as *Smith's* or the *vulgar temperament*, in which some keys were favored at the expense of others, has been much used in organs. While the keys of B \flat , F, C, G, D, and A are more perfect than on equally tempered instruments E \flat , A \flat , D \flat , and F \sharp contain some very harsh intervals. The bad fifths and thirds which exist in these keys are designated by musicians by the name of *wolf* intervals. This mode of tuning the organ is being more and more abandoned for the equal temperament, or an approximation to it. The different characters of the various keys often observed on the pianoforte, as well as the organ, could have no existence were the temperament absolutely equal, and arise out of the circumstance that this strict equality is not altogether adhered to in practice.

TEMPERANCE. *History of the Movement.*—The origin of the temperance movement dates from the beginning of the present century; and the merit of having taken the first steps in the matter belongs to America, where the vice of drunkenness appears to have reached an alarming height about that time. In the month of April, 1808, a society was established at Moreau, county of Saratoga, in the state of New York, consisting of 43 members; one of whose rules was as follows: "Art. 4. No member shall drink rum, gin, whisky, wine, or any distilled spirits, or compositions of the same, or any of them, except by the advice of a physician, or in case of actual disease (*also excepting at public dinners*), under the penalty of 25 cents, provided that this article shall not infringe on any religious rite." This society had other rules prohibiting members (under penalties) from offering any of the above liquors, or from being intoxicated; but though it continued to exist for 14 years, it does not seem to have accomplished much good. Gradually, however, the attention of the clergy and of philanthropical laymen was called to the subject; and after a series of sermons had been preached and published against a vice whose rapid progress was threatening (according to Dr. B. J. Clarke) to make the Americans "a community of drunkards," a society was started at Boston (Feb., 1826), called *The American Temperance Society*, "to restrain and prevent the intemperate use of intoxicating liquors." In 1829, *The New York State Temperance Society* was formed; and before the close of the year, 1000 local societies, with 100,000 members, were in existence, and a periodical, entitled *The Journal of Humanity*, established to promote the new movement. Rumors of the progress of temperance societies soon reached the old world, and in Aug., 1829, a society was started at New Ross, in the county of Wexford, Ireland, under the auspices of the rev. George Whitmore Carr, the members of which pledged themselves "to abstain from the use of distilled spirits, except as a medicine in the case of bodily ailment," and further, "neither to allow the use of them in their families, nor to provide them for the entertainment of friends." Simultaneously, a movement in favor of temperance was begun in Belfast and the north of Ireland, by the rev. Dr. Edgar, rev. Dr. Cook, and rev. Mr. Morgan, and before 12 months were over, 60 societies had been constituted, numbering about 3,500 members, both Catholics and Protestants. Meanwhile, Scotland had not been uninfluenced. As early as Oct., 1829, Mr. John Dunlop, of Greenock, a justice of peace for Renfrewshire, after lecturing on the subject of temperance in Glasgow, Sterling, and elsewhere, succeeded in forming a society at Greenock, the first in Scotland, and the precursor of *The Glasgow and West of Scotland Temperance Society*, formed in the ensuing November. Mr. Dunlop is thus entitled to be considered "the father of temperance societies in Great Britain." In his early labors, he was greatly assisted by Mr. William Collins of Glasgow, who became the editor and publisher of the *Temperance Record* (1830-35). The rules of *The Glasgow and West of Scotland Temperance Society* were substantially the same as those of the American and Irish societies—the members voluntarily agreeing "to relinquish entirely the use of ardent spirits, except for medicinal purposes," although "the moderate use of other liquors is not excluded." The zeal and activity of this society were remarkable. According to the report read at the first annual meeting (Dec. 30, 1830), it had circulated in the course of the year 425,300 tracts and 20,200 pamphlets, and numbered in Glasgow alone 5,072 adherents; while it was stated that throughout Scotland at large there were 130 societies, and 25,478 members. It is not necessary to follow further in detail the course of the temperance movement, *strictly so called*, in Scotland, except to remark, that numbers of the clergy now began to interest themselves in it, and at the close of 1831, there were 187 ministers of various denominations in Scotland connected with the cause; but we must now notice the introduction of a new and more stringent application of the temperance principle. On Sept. 21, 1830, Mr. John Davie, and several other members of the temperance society of Dunfermline, pledged themselves to "total abstinence from all intoxicating liquors—small-beer excepted, and wine on sacramental occasions;" and in the course of the next two years, "total abstinence societies" were started in Glasgow, Paisley, and other places. In 1830, the temperance movement

extended to England. Mr. Henry Forbes, a merchant of Bradford in Yorkshire, happening to be in Glasgow on business, had attended one of the meetings of the Glasgow society, became deeply interested, and on his return home took steps to organize a Bradford society (Feb. 2, 1830). Another society was formed at Warrington (April 4, 1830); a third at Manchester (May 12, 1830); and by the close of the year, about 30 temperance societies were in existence, numbering in all 10,000 members. In June, 1831, *The British and Foreign Temperance Society* was organized in London, mainly through the persevering efforts of Mr. William Collins of Glasgow. This was for many years the leading society of the party, its patron being the bishop of London, and its vice-presidents including several other prelates, distinguished officials both civil and military, and a few members of parliament. The pledge taken by its members was simple: "We agree to abstain from distilled spirits, except for medicinal purposes, and to discountenance the causes and practice of intemperance." We have not space to narrate its history and progress in detail, but we may notice that it was instrumental in awakening an interest in the temperance movement both in the army and navy, and that, in the course of a single year (1831-32), it could boast of having induced 400 old Greenwich pensioners to give up their grog!

Gradually, however, the more fervid friends of temperance in England arrived at the same conclusion as the Dunfermline "reformers"—viz., that a crusade against gin and other "alcoholic" liquors was not enough; that "beer" was the great cause of drunkenness in their country, and that nothing but total abstinence from all intoxicating drinks would cure the evil. The movement in this direction first took shape at Preston in Lancashire, in Sept., 1832, when Mr. Joseph Livesey, and some other members of the temperance society there, pledged themselves "to abstain from all liquors of an intoxicating quality, whether ale, porter, wine, or ardent spirits, except as medicines." An active propagandism in all the principal towns of Lancashire followed, and a considerable number of adherents were gained to the new cause. In Sept., 1833, according to the commonly received story (see Burne's *Tetotalter's Companion*, p. 333), the notable word *tetotal* was first used. A certain Richard Turner, or, as he was more generally called, "Dickie Turner," a plasterer's laborer or *lime-larry*, who was much given to holding forth in the Lancashire dialect at the meetings of the new sect, happened in the course of a philippic against temperance to say: "I'll hev nowt to do wi' this moderation—*botheration*—pledge; I'll be rect down tee-tee-total for ever and ever." "Well done, Dickie!" said Mr. Livesey: "that shall be the name of our new pledge." This origin of the word, which appears to make it but a stuttering pronunciation of *total*, has, however, been disputed; and it is affirmed that the term is simply a Lancashire phrase for final, thorough, or complete; thus, when a man is discharged merely for want of work, he is said to be *sacked*, but when discharged from inability to work, *tetotally sacked*. Whatever may have been the origin of the term, the new sect was resolved to be "thorough." In April, 1834, a *Youths' Temperance Society*, on strictly *tetotal* principles, was formed at Preston, and before a year had passed, it reckoned nearly 1000 members. By dint of zeal, respectable *tetotal* societies were also established at Manchester (Aug., 1834), Lancaster (Nov., 1834), Colne (Dec., 1834), Isle of Man (Dec., 1835), and numerous other places. Meanwhile (Sept., 1835), a conference of Lancashire and Yorkshire delegates was held at Manchester, and a new general society formed under the title of *The British Association for the Promotion of Temperance on the Principle of Total Abstinence from all Intoxicating Liquors*. This title clearly indicated the ambitious views of the new sect. It wished, and it hoped ere long, to speak in the name of the whole temperance party; and as early as 1836, one of the Yorkshire district societies, that of Wilsden, ventured to memorialize *The British and Foreign Temperance Society* of London on the subject of the total abstinence pledge. The answer that it received showed that a disruption was not far off. In Scotland and Ireland, the progress of *tetotalism*, as distinct from temperance, was not at first very marked; but its votaries were resolute, and held vehement discussions, public and private, with the advocates of the rival system, in which they were generally considered victorious by the crowds before whom they disputed. During 1834-35, *tetotalism* was struggling hard for recognition in London—the influential leaders of the old temperance society being dead against it. At length, however, owing to the persevering efforts of Mr. Livesey of Preston and other enthusiasts, the *tetotalers* got a footing, and, in Sept., 1835, established *The British Tetotal Temperance Society*, which, in Aug., 1836, was merged into *The New British and Foreign Society for the Suppression of Intemperance*. *Tetotalism* now in turn began to get the upper hand, and in the course of the next two or three years, the "moderate" party almost disappeared; the majority of its members doubtless passing over to the ranks of the total abstinents. But these new fell out among themselves. Up to 1839, *The New British and Foreign Society* had two pledges, the long and the short; the former including the "neither give nor offer" clause; and the latter omitting it. The more rigorous *tetotalers* made strenuous efforts to get the "short" pledge abolished, which were as strenuously opposed, and in a very brief period the whole *tetotal* world was up in wild commotion on the subject. Various meetings of "delegates" from the different societies in England, Scotland, and Ireland were held in London in May, 1839, under the presidency of earl Stanhope, and scenes of the utmost disorder ensued. The result was a temporary disruption, and the formation of two socie-

ties. Still the cause prospered in spite of fierce distractions. Strong provincial associations were formed in Yorkshire, Leicestershire, Lancashire, Norfolk, and Cornwall and Wales, almost always on the "long pledge" principle. In Scotland, the "long pledge" took deep root; indeed, after 1837-38, the "short pledge" was scarcely ever thought of. But it was in Ireland that the most brilliant successes attended the movement. In 1838, father Mathew (q.v.) commenced his extraordinary career, and in less than two years, 1,800,000 men and women were enrolled in *Ireland's Great National Total Abstinence Society*.

The subsequent history of the movement must be briefly sketched. In Nov., 1842, the disruption, above mentioned, of *The British and Foreign Temperance Society* was healed, and the two societies which that disruption had called into existence were amalgamated in *The National Temperance Society*. The work of proselytizing then went on vigorously. Innumerable tracts were circulated, and all Britain echoed with the noise of infinite speech. Excursions, processions, Exeter hall demonstrations, incessant tea-parties, etc., were got up with enthusiasm, which speaks volumes for the energy and sincerity of the teetotal agents. But in a less showy though more noble way, the missionaries of the new faith pursued their benevolent work in the lanes and alleys of large cities, the haunts of profligacy and dissipation, where they sought out the homes of drunkards, and tried (not without success) to rescue them from the power of the horrible vice that was dragging them to destruction. Action of this sort—whatever one may think of the movement as a whole—is to be spoken of only with reference. In Aug., 1846, *The World's Temperance Convention* met in London, on which occasion 302 delegates were present, representing different societies in the United Kingdom and the United States. Since then, the temperance cause has steadily, if not rapidly, progressed. It has recently been estimated that there are not fewer than 4,000,000 total abstainers (inclusive of juveniles) in Great Britain and Ireland, and a much greater number in the United States of America. Of late years, total abstainers have devoted themselves mainly or largely to advocating the necessity or propriety of imperial legislation on the subject of intoxicating liquor.

The most recent development of the temperance movement is that known as *Good Templarism*. It originated in New York in 1851, and rapidly spread through the United States. In 1868, the order established itself in England, in 1869 in Scotland, and in 1870 in Ireland. Its progress has been singularly rapid. In England alone, exclusive of Scotland, Ireland, and Wales, there were in 1875 no fewer than 3,570 "lodges," having 168,425 members, estimated in 1879 to have increased to more than 200,000 persons. These of course do not represent absolutely new adherents to the temperance cause. They are in many cases members drawn from the older temperance societies, though it is also an undoubted fact that the order has been very successful in making fresh converts to the cause of total abstinence. The name is derived from the famous *Knights Templars*, and originated in a fanciful analogy between the functions of the ancient order of military monks, and the modern disciples of temperance. As the former were enrolled to defend the holy sepulcher and the interests of religion, so the latter are banded together to protect Christianity against a worse foe than the Saracens, viz., "the drinking institutions of the land." It is professedly a *religious* movement, and its ritual is evangelical. Its platform is absolute prohibition of the manufacture, importation, sale, or use of all intoxicating liquors as beverages: but it owes its great popularity to certain peculiarities in its constitution, its picturesque or showy ceremonial, and its aim to combine social and festive amusements with missionary zeal.—See *Good Templarism*, by the rev. George Gladstone (Glasgow, 1872); as also the several regularly appearing magazines of the order, the *Good Templar*, the *Good Templars' Watchword*, etc.

Pleas and Counter-pleas.—The question of abstinence from intoxicating liquors is capable of being argued on three distinct grounds, *scriptural*, *physiological*, and *social*. We propose to furnish a brief synopsis of the leading arguments *pro* and *con* under each of these aspects. First, then, the *scriptural argument*.

The scriptural argument in favor of abstinence from intoxicating liquor may be briefly stated. The only "strong drink" mentioned in the Bible is wine. It is both praised and blamed. The question raised by teetotalers is: Are the sacred writers referring in both cases to the same kind of wine? This they deny, and endeavor to make good their denial by an appeal to the original Hebrew. On examination it is found that ten or twelve different designations for wine are used, but the two by far the most frequent are *yayin* and *tirosh*. The first of these is the generic term for wine, and therefore (say the advocates of total abstinence), as it *must* embrace fermented liquor, it is the word used when wine is denounced. Thus, it is *yayin* that is a "mockery" (Prov. xx. 1), that is not to be looked upon (Prov. xxiii. 31, 32), etc. On the other hand, when wine is praised, *tirosh* is the word used, and *tirosh* (it is asserted) means the wine in clusters, that is, the actual grape itself, or the unfermented juice thereof, then, as now, liberally drunk as a beverage by the inhabitants of Syria and elsewhere. The application of this view to the New Testament is obvious. If there was a wine that might be used, as well as a wine that was condemned—which, ask the teetotalers, would Christ and his apostles be most likely to sanction? The wine that "maketh red the eyes," that "biteth like a serpent, and stingeth like an adder," that "deceiveth," that "maketh drunken" and "mad;" or the wine that "maketh glad the heart," that is "good," a "blessing," etc.;

—in a word, *yayin* in any of its dangerous forms (*sábe*, from the root to “soak;” *chemer*, the “foaming or bubbling;” and *mésec*, *mzég*, *mamsac*, the mixed wines), or the innocent *tirósh*, that cheers, but not inebriates? It is conceived that there can be but one answer to this question, and that every candid and reverent Christian must be forced to the conclusion, that the wine which Jesus made at the marriage-feast at Cana of Galilee, and used in his last supper with his disciples, and which Paul advised Timothy to drink for his stomach's sake, was the unfermented, innocuous, and popular *tirósh*.

To this it is replied that the distinction made between *yayin* and *tirósh* does not exist. Both parties are agreed that the former term is the generic one (corresponding with the Greek *oinos*, the Latin *vinum*, and the English *wine*, with all of which it is believed to be etymologically connected); but it is denied by the scriptural opponents of total abstinence that *yayin* means fermented, and *tirósh*, unfermented wines, exclusively. Not to trench upon the chemistry of the question, which, it is affirmed, wholly disproves the possibility of the “juice of the grape,” being kept for any length of time without undergoing a process of fermentation, and thereby acquiring to a certain degree intoxicating properties, it is alleged that the etymology of *tirósh* does not favor the teetotal view. According to Gesenius, it is derived from the root *yarásh*, “to get possession of;” that is, of the brain. Dr. Lees, indeed, quotes Bythner as suggesting that it may have been so named because the vine was a “possession” in the eyes of the Hebrews; but this is extremely improbable, and in the absence of other explanations, that of Gesenius is certainly to be preferred. Again *tirósh* is not exclusively used to denote the “fruit” (strictly so called) of the vine; the dreaded *yayin* performs the same harmless function—e.g., in Jer. xl. 10, 12, where it is connected with a verb significant of “gathering,” and in Ps. civ. 14, 15, with another expressive of growth. It is even denied that *tirósh* is ordinarily to be so understood, for although, being mostly found in connection with “corn,” the verb applied to the consumption of that article of food is by *zaqam* made to apply to the “wine” also, yet in the only passage where the act of consuming *tirósh* alone is mentioned (Is. lxii. 8, 9), the verb is *sháthah*, which invariably signifies the act of drinking. Lastly, it cannot be shown that *tirósh*, when it does mean wine, means innocuous wine. No doubt, *yayin* is the one generally employed when wine is denounced, and *tirósh* when it is praised, but this is not uniformly the case, for in Hos. iv. 11, “whoredom and wine (*yayin*) and new wine (*tirósh*) take away the heart,” *tirósh* actually forms (as has been remarked) “the climax” of intoxicating influences. The conclusion, therefore, to be drawn from a consideration of Scripture is, that the distinction insisted on by total abstinents between the two terms—viz., that the one (*yayin*) means fermented, and the other (*tirósh*) unfermented wines, is one that cannot be maintained. Both must be held as referring to fermented intoxicating wine; and the praise of *tirósh* is simply to be considered a recommendation of the moderate use of ordinary wine, as the condemnation of *yayin* is to be regarded as a solemn prohibition of excess in the same.

The physiological argument in favor of total abstinence necessarily takes various shapes; for it is concerned with physiological questions which are yet, to a great extent, matter of opinion—of speculation and conjecture, not of science. A question arises upon three distinct points: 1st, the effects of alcoholic liquors in quantities sufficient to produce intoxication; 2d, their effects when habitually used in moderate quantities; 3d, the effect of abstaining from them altogether.

Upon the first point, teetotalers usually maintain that insanity, idiocy, almost every form of organic disease, many chronic, not a few acute disorders, are frequent results of habitual intoxication; that the children of drunkards are often idiotic, and have transmitted to them various diseases, which are produced by excessive drinking—which, therefore, tends to the deterioration of the race; that drunkards are always the first victims of epidemics; and that it can be shown from tables of mortality that drinking has a marked effect in shortening life. It is not disputed that many of these effects can be connected with the habitual use of liquors in excess; but as to some of the most striking of them, it is denied that they are physiological effects of such excess—being not direct results of hard drinking, but due to the bad conditions under which poor people who drink hard usually live. The question between teetotalers and those who differ from them, at this point, however, is only a matter of degree. The latter admit that alcohol, in narcotic or intoxicating quantities, produces only injurious results. In such quantities it has a deteriorating, a devalizing influence upon the brain and nervous tissue, and habitual excess in its use is attended by a progressive impairment of nervous structure, indicated at length by such results as epilepsy or delirium. See INTOXICATION. But the results of excess differ greatly, it is said, in the case of different persons, so that, not unfrequently, many years of hard drinking do not affect the system of the drinker in a marked degree.

It is upon the second point—the habitual use of alcoholic drinks in moderation—that the opinion of teetotalers seriously conflicts with that of many physiologists. The teetotal argument—leaving out minor points, such as an alleged effect of alcohol in impairing the digestion—may be stated thus: 1. Alcohol can never have been intended by nature for the food of men. It is never produced spontaneously in nature. The vegetable world yields in abundance the principles which form the flesh, and those which keep up the heat of the body, but the healthy plant never produces alcohol. In the body too, in health, food is never converted into alcohol. And the body does not

merely not produce alcohol; it treats it as a foreign element, and gets rid of it as fast as possible. 2. Alcohol in the body, by taking up the oxygen supplied through the lungs, checks the burning of tissue, upon which life and the production of energy, muscular or mental, depend; and similarly it impedes the efforts of the body to get rid of the waste matters which are the products of the burning. It thus lowers vitality, vitiates the blood, and prevents the production of healthy fiber. Toddy or beer taken at bed-time, instead of being favorable to health, has just the same effect, according to Dr. Carpenter, with sleeping in a four-post bed with the curtains carefully tucked under the bed-clothes. In either case, that is, there is a diminution of the supply of oxygen required for vital processes, especially for burning the waste of the body. 3. The stimulation produced by alcohol is succeeded by a recoil or reaction; and to produce a certain effect of stimulation, the quantity taken must constantly be increased. From this cause—to say nothing of social influences connected with drinking calculated to produce the same result—moderate drinking tends to pass into excessive drinking, about the evil consequences of which there is no dispute.

The physiological opinion opposed to those arguments is, that while alcohol, like other similar substances, has in large quantities a narcotic, a devitalizing effect, it has in small quantities a stimulating effect, between which and narcotism there is a difference, not of degree, but of kind. The stimulating effect is precisely the same with that of highly-nutritious and easily digested food; as regards the vital functions, it differs from the effect of ordinary food only in rapidity of production. It does not substitute an abnormal for the normal action of the bodily organs; it restores their natural functions; and it is capable of rectifying either deficient or redundant functional action. The only positive difference of effect between ordinary food and alcoholic stimulation is, that the latter does not, to any great extent, add to the bulk of the body. There is no recoil or reaction after it, except that, as in the case of ordinary food, the effect is exhausted after a time. There is nothing to support the belief in a reaction, except the depression involved in the gradual recovery from the narcotic effect of a large quantity of alcohol; but between the narcotic effect of a large, and the stimulating effect of a small, quantity, there is, as already said, a difference of kind—their connection is merely accidental. And the experience of mankind—the fact that moderate drinking does not usually pass into excessive drinking—sufficiently shows that it is not found necessary to increase the quantity used for stimulation. Since stimulation restores the natural functions, it, of course, is capable of removing the consequences of functions being perverted. Thus, it is maintained that, among other things, it gives relief from pain and muscular spasms, reduces the circulation when too rapid, produces healthy sleep, and removes general debility, as well as the fatigue of special organs. Whether it, to an important extent, affects the waste of tissue, or keeps waste matters in the blood, is at present undetermined; however this may be, there is no justification for holding that life is to be measured by the aggregation of tissue, or the rapidity of bodily changes. The notion that alcohol checks the burning of tissue by taking up the oxygen received by the lungs, originated when it was believed, upon the authority of Liebig (it was so believed until a few years ago, but the contrary is generally held now), that alcohol was altogether decomposed in the body. If these views are correct, it follows that alcohol, taken cautiously and in small quantities—the quantities varying with the circumstances and with the constitution of the individual—may be used not only with safety but with advantage.

Under the third head teetotalers, of course, maintain that total abstinence is highly favorable to health. They adduce their personal experience; the mortality statistics of one or two regiments and of ships' crews mainly, or entirely, made up of abstainers; the evidence of arctic voyagers on the one hand, and of travelers in tropical regions on the other, to prove that in every climate health can be maintained, and is most likely to be maintained, when no use is made of alcoholic drinks. On the other side, the fact that men of all races use alcoholic beverages is held to show that men, living as men must usually do, find those beverages useful, if not necessary. It is not disputed that many persons live in health without them—that persons having an abundance of wholesome food, not over-worked, living in well-constructed houses, and in wholesome air, can usually dispense with them. But when some, or all, of those conditions are wanting—which in towns, at any rate, happens in all but exceptional cases—it is alleged that a nearer approach to health is made when a moderate use is made of alcohol.

The social arguments in favor of total abstinence, though very weighty and earnestly insisted upon, can be indicated in a few sentences. It is affirmed that the use of alcoholic drinks is at the root of all the misfortunes of the poorest and most numerous class; that it is the chief cause of pauperism, the chief cause of crime, a frequent occasion of immorality; that it lowers the health and shortens the life of the great mass of artisans and laborers, makes their homes wretched, and exposes them and their families to the evils and temptations of chronic destitution. Then, such are the seductive influences of drink and good-fellowship, that moderate drinkers are in danger of becoming drunkards; thus the use of liquors effects the ruin of a considerable percentage of the middle and upper classes. Total abstinence is demanded as a measure of personal precaution, because no one who drinks at all is safe against falling into drunkenness; as a patriotic duty, incumbent upon those who desire the improvement of the poorer classes; as a duty

of example which every man owes to his neighbor, and which, involving self-denial, must have a favorable reflex influence upon character. On the other side, it is not denied that drinking is closely connected with, or that it exasperates, the misery undergone by the poor; but it is denied that it is the cause of the misery. It is maintained that drinking must be regarded as an effect of the bad conditions inherited by the poor, and under which they live. Persons born in close alleys, and brought up in foul air, living always from hand to mouth, often upon insufficient or unwholesome food, feel (it is said) a need of stimulants to support vitality. It is affirmed that the fluctuations of crime (properly so called) do not depend upon the amount of drinking, but—so far as they can be traced to one circumstance—upon variations in wages; that it is destitution, not drunkenness, that contributes most largely to the production of crime. The drunkenness, the crime, the pauperism, it is maintained, cannot be permanently reduced except through a material and moral improvement being effected among the poor. Then it is denied that moderate drinkers, in general, are in any danger of becoming drunkards; it is persons wanting in prudence, and of intemperate constitution, who are exposed to that danger.

Of late years total abstinents—in unison with others who, though not themselves abstainers, are anxious to promote public sobriety—have exerted themselves to obtain, in one shape or another, a legislative prohibition of the trade in drink. This movement was set on foot in Great Britain in 1853, by an organization called "the United Kingdom alliance," on account of the success which had crowned the exertions of teetotallers in Maine and many other of the United States. In Maine the liquor traffic was suppressed in 1846; the law was made more stringent by a provision for confiscating all alcoholic drinks in 1851; and though in 1856 the existing laws were repealed, and it became lawful to distill spirits, to sell spirits, and to have spirits in possession, drinking-houses continued to be prohibited. The "alliance" soon found that there was no possibility of carrying a Maine liquor-law through the British parliament; and they have accordingly confined themselves to asking for a permissive bill, enabling the ratepayers of a parish, if a majority of two-thirds of them should think fit, to suppress all public-houses within the parish. Hitherto they have been unsuccessful. They support the bill upon the merits by a variety of arguments. Alcohol, they say, being a poison, its sale ought to be subject to the same restrictions as that of other poisons. The legislature has admitted the exceptional and dangerous nature of the liquor trade, by putting it under strict regulation; in consistency, it should suppress it as a trade altogether. They allege that the amount of drinking in a place always varies directly with the number of public-houses; and then that the amount of crime and of pauperism varies directly with the amount of drinking. In 1857 Dr. Lees calculated the expense of the use of liquors to this country at 120 millions a year—the cost of the liquor being put at 60 millions, and the remainder of the amount made up by allowing for the crime and pauperism caused by drinking, the loss of time in drinking, and, through disease induced by drinking, the waste of life consequent upon it and many minor items. This money, it is said, if not spent upon drink, would have a marvelous effect in improving the condition of the poor. On the other side, it is maintained, *in limine*, that the subject-matter of this bill is so very important, and so full of difficulty, that parliament should not delegate its functions in respect of it to the ratepayers; also, that to do so would be to plant, in every parish in the country, the seeds of perpetual strife. Upon the merits it is said that a prohibitory law could not be carried out—at any rate, in large towns where the worst evils connected with drinking are found; and that systematic attempts at evasion would be made, which would demoralize the people, and put them in chronic antagonism to the law. Besides the arguments already stated upon this side, it is urged that—excepting the case of poisonous substances—it is no part of the duty of a governing body to say to its people: You shall not spend your money upon this or that; that it is unreasonable, in a fiscal point of view, to speak of the national resources being wasted upon liquors any more than upon tea or beef, or other substances that perish with the using; and that the power of procuring articles which are desired is what men work for—the great motive of industry. It is also maintained that compulsory abstinence from drink would not produce the same results as voluntary abstinence; that men would seek indemnifications, resorting, it might be, to other and more injurious narcotics than alcohol, and to vices which might be even more injurious than drinking. It is said that abstinence, to be valuable, must be a sign of a moral improvement; and that it is safest we should leave the poor to face the temptations of their situation, trying to fortify them against these temptations by education, by giving them just, moral, and religious views; at the same time holding before them the spectacle of temperance and its results in the case of the more comfortable classes.

The following are the leading organizations in Great Britain that, with various modifications of creed, carry on the temperance agitation. They can claim as directors and advocates men of acknowledged position and ability; and the aggregate sum of money spent annually is very great. The National temperance league, London (organ, the *Weekly Record*); the United Kingdom alliance, Manchester, with numerous branches (organ, the *Alliance News*); the church of England and Ireland temperance society, London (organ, the *Church of England Temperance Magazine*); the Scottish temperance league, Glasgow (organ, the *League Journal*); the National band of hope union, London

(organ. *Band of Hope Review*). Besides these, the Roman Catholic and Methodist branches of the temperance society form distinct organizations, while the order of *Good Templars* has its organs in the United States, and in England, Scotland, and Ireland.

TEMPERATURE OF THE BODY IN HEALTH AND DISEASE. It is universally admitted, as a result of the observations of numerous physiologists, among whom our own countryman, Dr. John Davy, stands pre-eminent, that although the range of temperature varies in different parts of the human body, the normal temperature at completely sheltered parts of the surface amounts to $98^{\circ}.4$, or a few tenths more or less in temperate climates; and that if there is a persistent elevation above $99^{\circ}.5$, or a depression below $97^{\circ}.3$, some form of disease is certainly indicated. (In warm-blooded animals, generally, the temperature is one degree lower at completely sheltered parts of the surface than in the back of the mouth, or other accessible internal parts.)

Some of the circumstances which cause a deviation from the normal temperature are mentioned in the article on ANIMAL HEAT. It may be further noticed, that exposure to cold without exercise, and sustained mental exertion, reduce the temperature, and that the amount of heat is at first reduced after a full meal, although, as stated in the above-named article, it subsequently rises. Moreover, in the tropics, the average temperature is nearly 1° higher than in temperate regions.

When the temperature rises in cases of disease, the following relation to its augmentation and that of the pulse has been established: *an increase of temperature of 1° above 98° corresponds with an increase of 10 beats of the pulse in the minute.* Thus, if the pulse is 60 at 98° , it is 70 at 99° , 80 at 100° , and so on. It is now established beyond all doubt, by the observations of Wunderlich, Virchow, and many other foreign physicians, and by Parkes, Jenner, Aitken, and Ringer in this country, that the preternatural heat which in certain cases can be detected by the thermometer, and may exist to the extent of 4° , 6° , or even 8° above the healthy average, and which varies in amount in different diseases, in different persons, and at different times of the same day, is the essential symptom of fever. Dr. Davy, in his *Physiological and Anatomical Researches*, vol. i. p. 206, describes the case of a lunatic soldier, in whom the accidental discovery that his temperature was 6° above the normal standard, led to the detection of tubercular disease of the lungs and intestines. Wunderlich, whose experience embraces at least half-a-million exact thermometric observations, bears unqualified testimony to the value of this mode of investigation in the early detection of disease, and as often furnishing an important guide to treatment. Some of these instances are quoted by Dr. Aitken in his *Science and Practice of Medicine*, 3d ed. vol. i. pp. 44-46.

We give in a condensed form a few of the more important of these observations. In *ague*, the temperature of the body begins to rise several hours before the beginning of the paroxysm, and after the disease *seems* to have disappeared, a periodic increase of the temperature may still be detected, and as long as this continues, the patient is not really cured. In *typhoid fever*, the rise of temperature, or its abnormal fall, will indicate what is about to happen three or even four days before any change in the pulse or other sign of mischief has been observed. A sudden fall of temperature has thus denoted intestinal hemorrhage several days before it appeared in the stools. A fall as low as 93° was noticed by Parkes in a case of this kind. When a person, who yesterday was healthy, exhibits this morning a temperature above 104° , it is almost certain that an attack of ephemeral fever or ague is coming on, and should the temperature rise up to or beyond $103^{\circ}.3$, the case will certainly turn out of ague or of some other form of malarious fever. If, during the first day of illness, the temperature rises to 106° , it is certain that the patient does not suffer from typhus or typhoid fever; and if the temperature of a patient, who exhibits the general signs of pneumonia, never reaches $101^{\circ}.7$, it is certain that there is no soft infiltration in the lungs. "In typhoid fever, a temperature which does not exceed on any evening $103^{\circ}.5$, indicates a probable mild course of fever. A temperature of 105° in the evening, or 104° in the morning, shows that the attack is a severe one, and forebodes danger during the third week. On the other hand, a temperature of $101^{\circ}.7$, and below, in the morning, indicates a very mild attack, or the commencement of convalescence. In pneumonia, a temperature of 104° and upward indicates a severe attack. In acute rheumatism a temperature of 104° is always an alarming symptom. In a case of jaundice otherwise mild, an increase of temperature indicates a pernicious turn. In tuberculosis, an increase of temperature shows that the disease is advancing, and that untoward complications are setting in. In short, a fever temperature of 104° to 105° in any disease indicates that its progress is not checked, and that complications may still occur."—*Op. cit.*, p. 21. We may further observe that, from the observations of Dr. Sidney Ringer, a persistent elevation of temperature exists as an invariable precursor of the growth of tubercle in any organ. As a general rule, when the temperature rises continuously to $106^{\circ}.2$, the prognosis is unfavorable; and when it rises to 110° , a fatal issue is almost certain. The diseases in which the highest temperatures have been observed are scarlatina, in which it has been noted at 112° , and tetanus, in which, at the period of death, it was $112^{\circ}.5$, and an hour afterward was $113^{\circ}.8$. In Dr. Aitken's work, the reader will find a series of diagrams illustrating the range of temperature in ague, erysipelas, measles, pneumonia, simple continued fever, scarlatina,

small-pox, typhoid and typhus fevers, etc., together with a full description of the instruments to be used, the method of using them, and practical rules for recording observations.

TEMPERED, or TOUGHENED, GLASS, glass in a peculiar molecular condition, produced by placing it while hot in a tight box containing oil. The box is tight to prevent ignition of the oil. The surface to variable depths, depending upon the conditions of the experiment, becomes very hard, and apparently tough, for articles of glass prepared by this method may be thrown with considerable violence upon the ground without breaking. When, however, they do break they are shattered into minute fragments, after the manner of prince Rupert's drops (q. v.), indicating that the molecules of glass are held together in a condition of strain, and this is shown to be the case by an examination of the optical properties of the glass. Continued jarring will produce disintegration, and the material will not bear to be ground. It is the invention of M. de la Bastie of France.

TEMPERING METALS. A peculiar effect is produced upon some metals by heating them to redness, and then suddenly cooling them. By this means, extreme hardness is obtained, especially in steel, which is so susceptible to this process, called tempering, that almost any degree of hardness and brittleness can be obtained. If, for instance, we make a piece of steel red hot, and then plunge it into cold water, it becomes hard and brittle when cold, and is actually, though slightly, increased in bulk. But if we reheat the metal, and allow it to cool slowly, it again becomes soft and malleable as before. Moreover, if we again reheat it, but not to redness, and cool it suddenly, it is still further softened. If, before reheating, the surface has been polished, a beautiful shade of color is produced by the heat, which is varied according to the temperature employed; and so exactly is this the case, that the experienced manipulator is entirely guided by the color produced, instead of by nice regulations of the heat applied. For ordinary operations, the metal is cooled by plunging it in cold water; but oil, mercury, and saline solutions are used for special purposes. An exact series of experiments has proved that the following colors are produced at the temperatures given: very pale yellowish, by 430° Fahr.; pale straw, 450°; yellow, 470°; brown, 490°; mottled brown, 510°; purple, 530°; bright blue, 550°; blue, 560°; dark blue, 600°.

TEMPLARS, KNIGHTS, a celebrated religious and military order, founded at Jerusalem in the beginning of the 12th c., by Hugues de Paganes, Geoffroy de St. Omer, and seven other French knights, for the protection of the Holy Sepulcher, and of pilgrims resorting thither. Baldwin II., king of Jerusalem, bestowed on this order their first place of residence; and an additional building was acquired from the abbot and canons of the church and convent of the temple, whence the order obtained the name of the "poor soldiers of the temple of Solomon," afterward abbreviated into templars. The knights were bound by their rule to hear the holy office every day, or if prevented by their military duties, to say a certain number of paternosters instead; they were to abstain from flesh four days in the week, and from eggs and milk on Fridays. They might have three horses and an esquire each, but were forbidden to hunt or fowl. In the earlier period of their history, the templars made a great show of poverty, contrasting much with their later condition. After the conquest of Jerusalem by the Saracens, they spread over Europe; their valor became everywhere celebrated; immense donations in money and land were showered on them; and members of the most distinguished families thought themselves honored by enrolment in the order. In every country where they existed, they had their governor, called the master of the temple or of the militia of the temple. The templars had settlements in England from an early period. The first was in London, on the site of Southampton buildings, Holborn; but from 1185 their principal seat was in Fleet street, still known as the temple. The round church which bears their name was dedicated by Heraclius, patriarch of the church of the resurrection in Jerusalem, in 1185, and the chancel was consecrated in 1240.

The templars were at first all laymen and of noble birth. Pope Alexander III., however, in 1162, authorized the admission of spiritual persons not bound by previous vows, as chaplains to the order, who were not required to adopt the military vows. A third class was afterward introduced, consisting of laymen not of noble birth, who entered as serving brothers, some of them being attendants on the knights, and others exercising trades in the houses or lands of the order. Eventually, many persons became affiliated members without taking the vows, for the sake of the protection afforded them. As the power and prosperity of the templars increased, so did their luxury, arrogance, and other vices, which gave the French kings a pretext for endeavoring to suppress them, and lay hold of their possessions. Accusations, many of which were absurd and incredible, were brought against them by two members of their own body. Their principal enemy was Philippe IV. of France, who induced pope Clement V. to accede to a scheme by which the whole members of the order were seized and imprisoned, their lands confiscated, and many of them tried, convicted, and executed for capital crimes. The English templars were arrested by command of Edward II.; and a council held in London in 1309 having convicted them of various crimes, most of which were probably imaginary, the king seized their possessions. In 1312 the whole order throughout Europe was suppressed by the council of Vienne, and its property bestowed on the

knights of St. John, to which latter order their English possessions were formally transferred by a statute of Edward II. in 1323.

The habit of the templars was white, with a red cross of eight points of the Maltese form worn on the left shoulder. Their war-cry was "beau séant;" and their banner, which bore the same name, was parted per fess sable and argent. They also displayed above their lances a white banner charged with the cross of the order. Their badges were the *Agnus Dei*, and a representation of two knights mounted on one horse—indicative of the original poverty of the order.—See Addison's *History of the Knights Templars, the Temple Church, and the Temple* (Lond. 1842); A. O. Haye's *Persecution of the Knights Templars* (Edin. 1865).

TEMPLATE, a mold in wood or metal, showing the outline or profile of moldings, and from which the workmen execute the molding.

TEMPLE (so called because the knights templars had one of their branches in that part of London), in its connection with the law of England, is a part of the city of London occupied exclusively by barristers or attorneys, with few exceptions. It is the joint-property of the two Inns of Court (q.v.), called the societies of the inner temple and middle temple, each of which has a right of calling persons to the degree of barrister—a privilege shared by the two other Inns of Court, Gray's Inn (q.v.) and Lincoln's Inn (q.v.). The temple consists of buildings occupied by barristers, who rent the same from the above two societies, who are the private proprietors, and issue their own regulations as to the management of the property.

TEMPLE, DANIEL, 1790–1851; b. Mass.; graduated Dartmouth college, 1817, and Andover seminary, 1820; sailed as a missionary of the American board to the east, 1822, with a printing-press; stationed at Malta, 1822–32, and had charge of the press; resided at Smyrna, 1832–44; returned to America, 1844. He published many books in modern Greek, Italian, and Armenian, wrote many scriptural histories, and edited and contributed to a monthly magazine in modern Greek. His life and letters were published after his death by his son, the rev. Daniel H. Temple.

TEMPLE, FREDERICK, D.D., b. England, 1821; graduated with the highest honors at Balliol college, Oxford, 1842; was fellow and tutor in mathematics; ordained in the church of England, 1846; principal of the training college, Kneller hall, 1848–55; an inspector of schools, 1855–58; master of Rugby school, 1858–69; appointed bishop of Exeter, 1869, his confirmation as such being ineffectually opposed because of his share in writing, 1860, the well known *Essays and Reviews*. He is one of the queen's chaplains, and has published three volumes of sermons preached in Rugby chapel.

TEMPLE, RICHARD GRENVILLE, Earl, 1711–79, b. England; returned to parliament from Buckingham, 1734; and in 1752 succeeded to the earldom. He was a political associate of William Pitt, and held the positions of lord of the admiralty, 1756–57, and lord privy seal, 1757–61. The *Grenville Papers* (1852–53), edited by W. J. Smith, consist of the correspondence between Pitt and George and Richard Temple. They throw much light on the political and court life of the period.

TEMPLE, SIR WILLIAM, an eminent diplomatist and popular writer, was the eldest son of sir John Temple, master of the rolls in Ireland. He was born in London in 1628, studied for two years at Emmanuel college, Cambridge (where he had the celebrated Dr. Ralph Cudworth for tutor), and at the age of 19 went abroad on his travels. He acquired the French and Spanish languages, and also cultivated his taste for English composition. He entered on public life in 1661, as member for the co. of Carlow, in the Irish parliament. In 1665 he was selected to proceed to Westphalia on a secret mission to the bishop of Münster; and on his return he was created a baronet, and appointed resident at the court of Brussels. He was, as sir James Mackintosh has remarked, the model of a negotiator, "uniting politeness and address to honesty;" while, as a domestic politician, "in an age of extremes, he was attached to liberty, and yet averse from endangering the public peace." In fact the chief aim and desire of this accomplished statesman was to enjoy lettered ease and leisure, apart from all exciting public care and responsibility. His most important diplomatic success was the famous treaty of 1668, known as the triple alliance, by which England, Holland, and Sweden bound themselves to unite in curbing the ambition of France. This negotiation was accomplished in five days, in conjunction with the great Dutch statesman, De Witt. At the congress of Aix-la-Chapelle, and at the subsequent treaty of Nimeguen, Temple was also a negotiator. He was long ambassador at the Hague, and assisted in bringing about the marriage of the prince of Orange with the princess Mary. Charles II. in vain endeavored to prevail upon him to accept the appointment of secretary of state; but though shunning such arduous duty, he attempted to reform the government by establishing, with consent of the king, a privy council of 30 persons, by whose deliberations his majesty promised to be guided in all public affairs. As might have been foreseen, so numerous a council, under such a sovereign as Charles, and in times of such fierce rivalry and faction, proved an utter failure. Temple then finally abandoned politics, and retired to the country. When the revolution placed William III. on the throne, Temple was again solicited to become secretary of state; but he again refused. The remaining 10 years of his life were mostly spent at his favorite seat of Moor park,

in Surrey, where he carried out his schemes of planting and landscape gardening, and realized his early wish for studious retirement. During this period he had, as secretary and humble companion, the immortal Jonathan Swift, who regarded his stately self-complacent patron with more fear and distrust than affection, but who ultimately became his literary executor. Temple died at Moor park, in Jan., 1699. His collected works form four volumes (Lond. 1814).

As an author Temple is now known chiefly by his historical *Memoirs*, and his *Miscellanea*, the latter being a collection of essays on various subjects—as government, trade, ancient and modern learning, gardening, heroic virtue, and poetry. He has been considered one of the reformers of our style; “the first writer,” says Johnson, “who gave cadence to English prose.” His style has quite a modern air, and is smooth, copious, and agreeable. He is too pretentious as respects scholarship and learning, and has no weight as a political writer; but he expatiates very pleasantly on foreign travel and country life, on flowers and fruits, on parterres, terrace-walks, and fountains. His epicurean temperament is happily and characteristically displayed in the last words of his last essay. “When all is done,” he says, “human life is at the greatest and best but like a froward child, that must be played with and humored a little to keep it quiet till it falls asleep, and then the care is over.” This is taking the battle of life very easily, but it is not in such a manner that great men or true patriots are formed.

TEMPLEMORE, a market-t. of the co. of Tipperary, province of Munster, Ireland, is supposed to take its name from a commandery of the knights templars, and is situated on the right bank of the river Suir, 9 m. n. of Thurles. Although without manufactures of any note, Templemore has some considerable share of inland traffic. It is a station on the Great Southern and Western railway, 79 m. distant from Dublin. The public buildings, one of which is an extensive barrack, are substantial, but without any noteworthy, architectural character. The pop. in 1871 was 3,497, of whom 2,493 were Roman Catholics.

TEMPO (Ital. time), the degree of rapidity with which a piece of music is to be executed. The rhythmical proportions of notes, as indicated by their form, give them only a relative value, and have no reference to the absolute speed with which the composition should be played. Some compositions require, from their character, a quick lively movement; for others, a slower movement is more suitable; and different terms are used to indicate different gradations of movement. Of these the principal, beginning with the slowest, are: *Largo*, broad; *larghetto*, somewhat broad; *lento*, dragging; *grave*, heavy, solemn; *adagio*, slow; *andantino*, moving a little; *andante*, moving; *allegretto*, somewhat lively; *moderato*, moderately quick; *allegro*, lively; *vivace*, with vivacity; *presto*, rapidly; *prestissimo*, with great rapidity. These terms are not always used with the precision that might be wished, and sometimes apply more to the character than to the absolute speed of performance. They are often modified by other qualifying words, as *allegro con brio*, lively and with briskness; *allegro appassionnato*, passionately excited. The *tempo* is indicated with more exactness by a reference to the beat of the metronome (q.v.). Thus, M.M. ♩ = 120, signifies that 120 beats of the metronome, each representing a crochet, are to fill up the space of a minute; M.M. ♩ = 60, that 60 quavers are to be performed in a minute.

While the general rule is, that the time of a movement is to be steady and unvarying, cases often occur where a certain part of a composition has to be taken quicker or slower than the rest; this is indicated by such terms as *più vivo*, more lively; or *ritenuto*, kept back; while a return to the original time is expressed by the words *a tempo*. The performer may be required to proceed from one degree of movement to another, not abruptly, but gradually; the time used to express this are: *ritasciando*, slackening; *ritardando*, retarding; *calando*, calming down; *stringendo*, pressing on; *accelerando*, gradually increasing speed; with some others.

TEMPO RUBATO (stolen time) is the name given to a mode of performance in which a restless character is imparted by protracting one note beyond its proper duration, and curtailing another, so that the aggregate duration of each measure remains unchanged.

TEMPORAL BONES. See **SKULL**, *ante*.

TEMPORAL POWER (OF THE POPE) is a phrase susceptible of two meanings, which are very distinct from each other, and the confusion of which has led to frequent and serious misunderstanding.

I. In one of these senses it means the sovereign power which the pope possessed as ruler of the so-called papal states (q.v.), and which, especially of late years, has been the subject of much controversy. The power which the pope exercised within his own states, although modified in its exercise by his spiritual character, was in substance the same as that of any arbitrary sovereign. The history of its origin and progress, and of the variation of the limits within which it has been acknowledged, is briefly detailed under the head **PAPAL STATES**. The question as to the necessity or utility of such a power vested in the hands of a spiritual ruler, and even of its lawfulness and its compatibility with his spiritual duties, has been very warmly debated; nor is this controversy of entirely recent origin. Many of the mediæval sectaries put forward the principle of the incompatibility of the spiritual with the temporal power in the same person, not only in relation to the pope, but also as to the baron-bishops or other ecclesiastical

seigneurs of that age. Such were the doctrines of the Vaudois, of Pierre de Bruis, and above all, of Arnold of Brescia. The last-named of these rendered himself specially obnoxious by the activity and even turbulence with which he propagated this view, and the sentence of death under which he suffered was the penalty of rebellion quite as much as of heresy. Through the centuries which followed, the anti-papal controversies turned so entirely upon doctrine, that there was little room for the discussion of this question, and it is a mistake to suppose, as has not unfrequently been done, that it entered in any way into the conflict of Gallican and Ultramontane principles. Even the great Gallican champion, Bossuet, not only admitted the lawfulness of the pope's temporal sovereignty, but contended that it was in some sense necessary to the free exercise of his spiritual power, and to the independence of his ecclesiastical government. It was not until the aggression of the French republic upon Rome, and the annexation of the papal provinces called the Legations to the Cisalpine republic, and afterward to the kingdom of Italy, by Bonaparte, that the controversy assumed any practical interest. During the later conflict between Pius VII. and Napoleon I., the design which the latter entertained of a still further annexation of papal territory was one of the main causes of dispute; and still more recently, after the re-annexation of nearly the same portions of the papal states to the kingdom of Italy, the question once more agitated the entire Catholic world. No formal and authoritative judgment of the Roman church was pronounced regarding it; but a strong and almost unanimous expression of opinion was tendered to the present pope, Pius IX., in the form of letters and addresses from bishops and others in every part of Catholic Christendom. The tenor of all these is nearly the same. They profess that the possession of temporal sovereignty is no essential part of the privileges of the successor of St. Peter; but they also regard the possession of a sovereignty independent of any particular sovereign, as the means providentially established for the protection of the spiritual independence of the pope, and of the free exercise of his functions as spiritual ruler of the church. The contrary opinion held by some distinguished members of the Roman church, although regarded with great disfavor, was not formally condemned by a doctrinal decision, nor was any action taken on it in the Vatican council. The recent annexation of the city of Rome itself to the kingdom of Italy elicited a still stronger expression. The event is noticed in the article papal states (q. v.).

II. By the second signification of the phrase "temporal power of the pope" is understood what would more properly be called the claim of the pope, in virtue of his office, to a power over the temporalities of other kings and states.

This power may be of two kinds, *directive* and *coercive*. In the first sense, it is a claim which no Catholic, consistently with his belief of the spiritual supremacy of the pontiff, can be supposed to deny, as it imports nothing more than that the pope, as supreme moral teacher, has power to instruct all members of his church, whether subjects or sovereigns, in the moral duties of their several states.

If the power be regarded as coercive, it is necessary to distinguish the nature of the coercion which may be employed. That coercion may either consist in the threat or infliction of *purely spiritual censures*; or it may involve temporal consequences, such as suspension or deprivation of office, forfeiture of the allegiance of subjects, and even liability to the punishment of death. Considered in the former sense, the claim must be regarded as a natural consequence of the spiritual headship of the church, which is acknowledged by all Catholics; nor can it be denied that the power to compel sovereigns, by purely spiritual censures, to the fulfillment of the moral duties which their state imposes, is a natural concomitant of the spiritual primacy.

But the papal claim to authority over the temporalities of kings has gone far beyond these limits. From the 10th c. downward, popes have claimed and have repeatedly exercised a power of coercing kings, and punishing them when refractory by suspension, by deprivation, and by the transfer of the allegiance of their subjects to another sovereign. This well-known claim has been a subject of controversy in the Roman Catholic church between the Gallican (q. v.) and Ultramontane (q. v.) schools; and in the Ultramontane school, two different theories have been devised for its explanation. The first and most extreme (which holds the power to be a direct one) supposes that this power was given directly by God to St. Peter and his successors, that the two powers are fore-shown by the "two swords" mentioned in Luke xxii. 38, and that the temporal power is a privilege of the primacy by divine law, equally with the spiritual sovereignty itself. According to the second, or *indirect* theory, the temporal power is not directly of divine institution, but is an indirect though necessary consequence of the spiritual supremacy; and is only given as a means of completing, and, in a corrupt and disorganized state rendering more efficacious, the work which the spiritual supremacy is directly instituted to accomplish. It was in this latter form that the theory of the temporal power was defended by the great champion of Ultramontanism, cardinal Bellarmine, and the celebrated declaration of the Gallican clergy (*Declaratio Cleri Gallicani*) in 1682 (see GALLICAN CHURCH) was directed against it.

A third view of the temporal power, and one which has found many modern defenders, was propounded by the celebrated Fenelon (q. v.). According to Fenelon's theory, which is generally described as the historical theory of the temporal power, the pope does not possess, whether by direct divine appointment, or in virtue of the necessities of his spiritual office, any temporal power whatsoever. But he possesses the

plenitude of that spiritual power which is required for the government of the church, and he is empowered to enforce it by spiritual penalties, and especially by excommunication or deprivation of membership of the church. Now, although excommunication and such other penalties, of their own nature, are purely spiritual, yet the religious sentiment of the medieval period, and the awe with which it regarded the authority of the church, invested these penalties with certain temporal effects. See EXCOMMUNICATION.

The penalty of forfeiture of certain civil rights was attached by the law of England, in the case of private persons, to the spiritual censure of excommunication (q. v.). The same penalty was applied by the laws of other countries to the sovereigns themselves; by the law of Spain in the sixth council of Toledo in 638; that of France, as confessed by Charles the Bald in 859; the law of England, under Edward the Confessor, and the so-called Saxon and Swabian codes of Germany. The last-named codes recognize in the pope, in certain specified cases, the right to excommunicate the emperor himself; and ordain that in case the emperor should remain for twelve months without being absolved from the excommunication, he shall be deposed. In the appeal of the Saxon nobles to the pope against Henry IV., this law is expressly referred to. The contemporary historians, Paul of Bernried, Lambert of Aschaffenburg, Nicholas Roselli, and others, describe it as the ground of the emperor's deposition; and even Henry himself, without denying the force of the law, sought his defense solely in a denial of the charge of heresy which was imputed to him. The same spirit of the age is exhibited in the form of oath taken at the coronation of the sovereign in many countries, especially (although not exclusively) in those whose kings—as Roger of Sicily, Peter III. of Aragon, Guiscard of Naples, Godfrey of Jerusalem, and John of England—had made their kingdoms feudatory to the see of Rome; by which the monarch swore to be the protector and defender of the sovereign pontiff and the holy Roman church in all their necessities and utilities, and to guard and maintain their possessions, honors, and rights.

From these and similar indications of the public feeling of the mediæval time, the advocates of this theory of the temporal power infer that orthodoxy and obedience to the pope, in all essential matters of faith and discipline, were by the consent, express or tacit, of sovereigns and of peoples accepted as a condition of the tenure of supreme civil authority—a condition similar in its character and objects to that which forms the basis of the limitation settlement of the succession to the English crown, to the heirs of the princess Sophia of Hanover, “being Protestant.” Hence they conclude that the function really exercised by the popes in relation to heterodox or scandalously immoral sovereigns, or oppressors of the church and church liberties, was in itself a spiritual one, and that the civil consequences which it entailed of deprivation or deposition arose, not from the church law, but from the expressed or understood international civil law of the age. This notion of the origin and nature of the pope's power over sovereigns and states may be regarded as the view now commonly received, and it may help to a better understanding of some points of the controversy regarding the celebrated Syllabus. It may be added, that this view is not confined to Catholic writers, but is held by Leibnitz, Pfeffel, Eichhorn, Voigt, Frederick Hurter (while still a Protestant), and others.

On the other hand, it is difficult, if not impossible, to reconcile this theory with the language used by the popes themselves in enforcing their claim to temporal authority, and with the arguments upon which they rest that claim. Nor can it be denied that whatever is said of the cases of the exercise of such a power which occurred in the 12th and 13th centuries, the power continued to be claimed and to be exercised down to and even after the reformation, when it would be idle to suppose that any such public understanding, if it had existed in the middle ages, had not been revoked, if not by all, at least by those nations which had revolted from the Roman church.

The history of most of the principal instances of the exercise of this power by the popes, will be found detailed under the separate articles which refer to the particular popes or sovereigns who engaged in the contest of church and state.—See Gosselin's *Pouvoir du Pape au Moyen Age*.

TENACITY (Lat. *tenacitas*, power of holding) is that property of material bodies by which their parts resist a force employed to attempt to separate them. It is the result of the attractive forces exerted by the particles of matter upon one another through the infinitely small spaces which are supposed to exist between them; hence it differs in different materials, and even in the same material at different degrees of temperature. The practical bearings of the tenacity of solids (especially of wood and iron) are discussed in the article STRENGTH OF MATERIALS; and we shall therefore here only state a few of the conclusions at which Muschenbroek and other experimentalists have arrived regarding the modifications which the tenacity of metals undergoes in consequence of various processes. Forging and wire-drawing increase the tenacity of metals in longitudinal direction. Copper and iron have this property more than doubled, while gold and silver have it more than trebled by these metals being drawn into wire. Mixed metals have usually a greater tenacity than simple ones. See ALLOY.

TENAILLE, in fortification (q. v.), a work in low relief, constructed immediately in front of the curtain. It may either have two faces, in a line with the faces of the adjoining bastions, and meeting at the center in a re-entering angle; or three faces, of which two are prolongations of the bastion faces, and one parallel to the curtain. The *tenaille*

must be low enough for the defenders to be safe from the musketry-fire on one bastion defending a breach in the other bastion. This work is of great use in protecting the ditch, covering the postern from the enemy's view, etc.

TENANCY AT WILL, in point of law, means an occupation by a person in the character of a tenant, but for no fixed term other than the will or caprice of the landlord or proprietor. In general, courts are averse to assume a tenant to be a tenant at will, if there are materials to satisfy the description of a yearly tenant. Rent is payable, under a tenancy at will, according to the time of occupation, and the tenancy can be determined by either party at any time. But the tenant is not to be prejudiced by the sudden determination of the tenancy, so that if he has sown the lands, he is entitled afterward to re-enter the lands, to reap the crops; and, in like manner, he has a reasonable time to remove his furniture.

TENANCY IN COMMON, in point of law, means a right to hold or occupy lands, or possess chattels, along with another or other persons. In such a case, each has an equal interest; but in the event of the death of either, his share does not go to the survivors, as is the case in joint tenancy (q.v.), but to his heirs or executors. Tenancy in common applies to ownership as well as leasehold interests. Though each tenant has as much right to the whole property as the others, yet neither has a definite share set apart to himself exclusively. If one wastes or deals with the property to a greater extent than his share, the others can bring an action against him. Each can at any time compel a severance of the property, so that thereafter he may have his own share severally.

TENANCY IN COMMON (*ante*). The undivided interests of tenants in common need not be acquired at the same time or by the same title by all the tenants, and they need not be the same in amount. The share of each tenant is subject to his debts, and to dower and courtesy. His power over it is absolute. He may make a conveyance of it, devise it by will, or incumber it by mortgage. In most of the states the common law rule has been so changed by statute that what would be a joint tenancy in England is in this country a tenancy in common; so that persons who take land in undivided shares by will or deed are tenants in common. A tenant in common can always compel partition. See PARTITION.

TENANCY ON SUFFERANCE differs from a tenancy at will in this, that a tenant at will enters on a good title, whereas a tenant on sufferance has no title, and wrongfully continues. Thus, when the term has ended, and the tenant has got notice to quit, but does not, he continues a tenant on sufferance, and may be ejected at any time, unless the landlord elect to treat him as a tenant in continuation of the former lease.

TENANT FOR LIFE, in English law, means one who has not the absolute property, but an interest in the property, which ceases with his own life, or the life of another. An estate for life in lands is classed with freehold estates. Where the estate for life depends on the life of a third person, as it is the interest of the tenant that such third person should live as long as possible, frauds are often committed on the reversioner by misrepresenting the fact of such person being alive; hence, to prevent fraud, the reversioner may insist on the third person being produced, failing which he will be taken to be dead. An estate for life is usually created by deed, but there are two legal estates for life—namely, the widow's estate in dower, and the husband's estate by courtesy on his wife's death. As a general rule, a tenant for life of real estate is entitled to take wood to repair and burn in the mansion of the estate; but he cannot for other purposes fell the trees, nor open mines or pits, though, if these have been already opened, he may carry them on. Sometimes a tenant for life is declared by the deed or will to be tenant without impeachment of waste, in which case he can exercise most of the rights of an absolute owner, except cutting down ornamental timber, or defacing the family mansion. Tenants for life may now apply to the court of chancery for leave to raise money to drain the lands and make improvements. When a tenant for life dies between the usual terms for drawing rent, the rent is apportioned between his executors and the party next entitled. A tenant for life is called, in the law of Scotland, a life-renter (q.v.).

TENANT IN FEE SIMPLE, in English law, is the old feudal description of one who is absolute owner, the fiction being that all were originally tenants of the crown. A tenant in fee simple has a freehold estate of inheritance, which is the highest degree of property known to the law. There is practically no feudal connection with the crown, and he can alienate or devise the property without the leave or sanction of the crown. A tenant in fee simple has an absolute right to the soil and the mines down to the center of the earth, and has a right to build as high as he pleases. If he dies, the estate goes to his heirs, i.e., his heirs general; but he has power to devise it to whom he pleases, subject to certain restrictions, in cases where the donee is a charitable corporation or trustee for charitable purposes. See MORTMAIN. A tenant in fee simple is called, in the law of Scotland, a *fiar* (q.v.).

TENANT IN TAIL. See TAIL, ESTATE.

TENANT-RIGHT. This term is used by tenants to denote the various claims of right which they may maintain against their landlords, such as the right of occupancy not subject to removal; and the right to occupy at a rent not subject to increase on the ground of improvements; it being said to be inequitable to make

them pay rent for what they have themselves produced. It is in Ireland that the claims have always had most importance. In Ulster, and in the north of Ireland generally, the equity of them has long been recognized and acted upon. In the south of Ireland, on the other hand, tenant-right was never conceded by the proprietors; while the right of occupancy not subject to removal, has, *de facto*, been enjoyed by the tenants. The non-settlement of the question was long the cause of bitter controversy, and undoubtedly its evil condition was the root of much of the national misery. Owing to the old tenure of land as tribal or clan property, the people of the south of Ireland never received into their minds the notion of "contracting" with any one as the "owner" of land. They had the traditional feeling of being themselves the owners; and so much was this feeling a source of agrarian disturbances, that few Irish "landed proprietors" have ever ventured fully to exercise their rights of property. And nothing was more common in the south than to find that the land had been in the occupancy of the same families from time immemorial without lease or contract of any kind.

The discontent in Ireland continued unabated till the British government interfered and settled the claims, in so far as was practicable at the time, on equitable principles. The passing of the landlord and tenant act of 1870, marked an epoch in the history of Ireland. Under it the Ulster tenant-right custom and all corresponding customs received the force of law, and when the matter did not admit of being regulated by a definite custom, the outgoing tenant became entitled to compensation from the landlord to an amount varying from one to seven year's rent, according to circumstances. The act also contained various provisions, giving compensation for improvements. It would be too much to say that this act has produced contentment, but it has greatly diminished the dissatisfaction, and has opened the way to the ultimate solution of the whole question. To Mr. Gladstone is due the principal share of the honor of passing it, but some of its best clauses were the work of Mr. Bright.

The Irish claim of tenant-right very much resembles that made by the Indian ryots against their zemindars. In India, as in Ireland, until what may be called recent times, land belonged to families or communities, which held themselves to be composed of kindred; but by acts passed by our government, a class of mere tax-collectors have been converted into land-owners, in order to facilitate the collection of the revenue. Hence, there has been in India an agitation very much resembling that which prevailed in the south of Ireland. The ryot claim of tenant-right was made the subject of a suit before the supreme courts of India, when a majority of the judges favored the equitable claim of the ryots. In countries where the people have been trained in notions derived from the Roman or feudal laws, there has been little heard of this species of claim of right, and land has been recognized by the people as being, like other things, a fair subject for contract.

In Scotland and in the north of England farms are almost always let on long leases, and at such rents as are supposed to repay the tenant the capital which he may lay out in improvements; and the common case is, that the landlord binds himself to pay the tenant a stipulated sum as the value of his improvements, provided that these are found at the end of the lease to be of a certain stipulated value. Over England generally, on the other hand, tenancy can be ended by six months' notice on either side, and the evils incidental to this precarious tenure have been obviated or mitigated solely by the honorable conduct of the English proprietors. It is quite common in England to find that the son has succeeded the father as tenant-at will for many generations, often for centuries.

Since the admission of the claim to tenant-right in Ireland, it has been more frequently heard of in the other parts of the United Kingdom, especially in the form of a claim to compensation for permanent or unexhausted improvements made by the tenant. Of the equity of this claim there can be no doubt, and the law might easily be altered so as to admit of effect being given to it. As matters at present stand, there is little inducement for a tenant to improve the land. The law by which the ownership of improvement follows the ownership of land, is in the present condition of things in the highest degree unjust and inexpedient. The tenant's interest in all his improvements ending with his tenancy, he is very unlikely, at least toward the end of his term, to spend anything on the land which will be of benefit to it; and where he is a tenant-at-will, he is entirely without interest to improve it.

TENASSERIM, acquired by Britain after the war in 1825, is the third or southernmost division of British Burmah* (q.v.)—the other two divisions comprising the ancient kingdoms of Pegu and Aracan. On Jan. 31, 1862, these three maritime provinces were united under one local administration, bearing the name of British Burmah.

Tenasserim is a narrow line of coast about 500 m. in length, with a varying breadth of from 40 m. at its southern extremity to 80 m.; the latter distance being measured from the sea-shore at the mouth of the Salween to the range of mountains on the e. that separates Tenasserim from Siam. It extends lengthwise from the southern

*The provinces of British Burmah extend along the eastern shore of the bay of Bengal from the Naf estuary, in about 20° 50' n. lat. to the Pak-cha river, in about 10° 15', with a coast-line of 900 English miles. Their area and population, according to the latest returns, 1872, are as follows: Aracan, area 14,526 sq.m., pop. 484,363; Pegu, area 27,300 sq.m., pop. 1,662,058; Tenasserim, area 46,730, pop. 600,727.

border of Pegu in 17° 50' n. lat. to near the tenth parallel of n. lat., and from 97° 30' to 99° 26' e. long., and has a total area of 46,730 sq. miles. Tenasserim is divided into six administrative districts, besides the town of Moulmein: Toungu, area 6,354 sq.m.; Schwe-gyen, 5,567 sq.m.; Salwen, 4,646 sq.m.; Amherst, 15,193 sq.m.; the town of Moulmein, 10 sq.m.; Tavoy, 7,200 sq.m.; and Mergui, 7,760. The principal town is Moulmein, the next in importance being Toungu and Mergui.

Physical Features.—The general aspect of the country is bold and picturesque. The numerous wooded ranges of hills take generally a course from n. to south. The northern part of the country is the most level; the southern portion is little else than a wilderness of thickly-wooded hills, inclosing long and narrow valleys. The soil of the plains is very fertile, and suited to the growth of rice, indigo, cotton, sugar, and vegetables. Tobacco grows chiefly on the banks of rivers in the hills. Only about $\frac{1}{15}$ of the country is under cultivation, and the forests occupy two-thirds of the entire area. The chief rivers are the Salwen, Gyne, Attaran, Yé, Tavoy, and Tenasserim. The Tenasserim, from which the country derives its name, is the most considerable river of the province. The principal ports of Tenasserim are Moulmein (q.v.), Amherst, Tavoy, and Mergui, of which Moulmein is the best. Amherst harbor, at the mouth of the Salwen, affords good anchorage for ships of any draught of water, but is difficult of approach. The Mergui archipelago, lying off the southern coast of Tenasserim, consists of almost innumerable islets, some of which are said to be rich in iron ore; and they are famous for their edible birds' nests. Numerous anchorages are found among the islands. The country possesses vast stores of mineral wealth, which now lie absolutely neglected. Gold-washing has been pursued with success at the head of the Tavoy river. At Kahan, on Mergui island, are rich and accessible tin-mines; and thousands of tons of good clean ore, yielding 75 per cent of the pure metal, could be raised not far from the surface of the ground. A very productive iron ore is obtained from Iron island, between Tavoy and Tiger island. Mergui province furnishes a valuable lead ore, and has extensive fields of coal. Manganese has been found on the Tenasserim river, where it is believed to be very plentiful.

Botany.—The botanical productions of Tenasserim may vie with those of any part of the world. There are more than one hundred different kinds of timber-trees, of which the teak is the most important. The celebrated *Amherstia nobilis* is the most splendid of the many flowering and ornamental trees for which Tenasserim is famous. The palm tribe are in great variety, and Dr. Griffith collected 1700 different species of plants in about 14 months.

The *climate* of Tenasserim is regulated by the monsoons; and the wet and dry seasons divide the year into two nearly equal parts. The average yearly fall of rain is about 194.28 inches, and this descends during the six rainy months from May to October. The greatest amount of rain ever recorded as having fallen in one day (May 27, 1857) is 12.75 inches; and the gauge for the week registered 40.27 inches (Dr. Walter). While the rains last, the temperature is very uniform, the thermometer ranging between 76° and 82°. The cool season lasts from the cessation of the rains in October, when the north-east monsoon begins, to the middle of February. During that time, the thermometer seldom reaches 90° in the shade, and occasionally falls at low as 56°, and now occurs the greatest thermometric range, which is sometimes as much as 30° in one day. The sun then gradually regains its power, and the heat increases daily till the south-west monsoon again brings clouds and rain. In the hot period, the thermometer at mid-day is not often below 92° in the shade, and not unfrequently stands at 95°.

Commerce.—The principal exports from Tenasserim are teak, timber, and rice. The trade of the province is, however, not on the increase. The first two articles of export mentioned are not continuous from year to year; and we accordingly find that the decrease in the value of trade is owing to the diminished demand for teak timber. Indeed the defective continuity of supply is to some extent a fact also as regards timber. Rice is the most reliable article of commerce.

Inhabitants.—In 1872 the pop. of the Tenasserim districts was as follows: Toungu, 86,166; Schwe-gyen, 129,485; Salwen, 26,117; Amherst, 193,468; Moulmein (town), 46,472; Tavoy, 71,827; Mergui, 47,192; total pop. of Tenasserim, 600,727. Most are Burmans proper, but there are other races, as Talaings, or descendants of the ancient Peguans; Karens, a dispersed people, inhabiting secluded mountain districts—among whom Christianity has made some progress, through the labors of American missionaries; Tounghoos, Khyengs, Shans, Europeans and their descendants, Chinese, and Indians. Throughout Tenasserim and British Burmah generally, inheritance and marriage are regulated by Buddhist law, while at the sea-ports the English mercantile law and law of contracts are in force, and regulate the decisions of the courts.—*The Natural Productions of Burmah and the Tenasserim Provinces*, by the rev. F. Mason, A.M. (Moulmein, 1850); *Six Months in British Burmah*, by Christ. T. Winter (Lond. 1858); *The Tenasserim and Martaban Directory* (Moulmein, 1857); *Reports of the Administration of the Province of British Burmah, for 1861–1862, and 1863*, by lieut.-colonel A. P. Phayre, c. b., chief commissioner and agent to the governor-general (Rangoon, 1862, 1863).

TENBY, a small parliamentary and municipal borough, and thriving watering-place, of South Wales, in the county of Pembroke, and 10 m.e. of the town of that name. Its

charming situation on a peninsula, overlooking the bay of Caermarthen, its salubrity of climate, and the facilities for bathing which the extensive sands in the vicinity afford, have made it one of the best and most fashionable watering-places in Wales. A considerable part of the ancient embattled walls of the town still remains. There are also a handsome church and picturesque ruins of a castle. The season lasts from June till October, and the number of permanent winter residents is annually increasing. Fishing is extensively carried on. Pop. '71, 3,180; but during the season the number is greatly increased.

TENCH, *Tinea*, a genus of fishes of the family *cyprinide*, of a thick form, with small scales, and a barbel at each side of the mouth, the teeth on the pharynx compressed and club-shaped. The COMMON TENCH (*T. vulgaris*) is an inhabitant of ponds and other stagnant waters in Europe and the north of Asia. It passes the winter in a torpid state, concealed in the mud. It is of a deep yellowish-brown color, more rarely golden or greenish. Instances have occurred of its attaining a length of 3 ft., but a tench of half that length is unusually large. It is very tenacious of life, and, like the carp, can be conveyed to a distance alive in wet moss. It spawns in May and June, depositing its spawn among aquatic plants. The ova are very small and very numerous. The flesh of the tench is soft and insipid, except when it is very well fed, when it becomes delicate and pleasant. It is commonly placed in ponds along with carp; a much smaller number of tench than a carp, however, being deemed sufficient to stock a pond. In Britain, the tench is found only in England, and there sparingly in some of the slow and muddy rivers. It is not improbable that it may have been originally introduced as a pond-fish, although it has long been naturalized. Angling for tench resembles angling for carp. The same kinds of bait are used.

TENCIN, CLAUDINE ALEXANDRINE GUÉRIN DE, 1681-1749; b. Paris; at first a nun; absolved from her vows in 1714. She lived in Paris with her brother, afterward cardinal, where she gained riches out of John Law's schemes. She was the mistress of cardinal Dubois, and of the regent, and other eminent men; and was the mother of D'Alembert by the poet Destouches. She was arrested, but acquitted, in 1726, on the charge of having endeavored to make away with La Fresnay, one of her numerous admirers, who had committed suicide at her house. She was the friend of Fontenelle, Montesquieu, and other literary men. Among her works are: *Le Siège de Calais*, an historical novel (1739-40); and *Les Malheurs de l'Amour* (1747).

TENDA, COL DE, a pass over the Maritime Alps. See ALPS.

TENDER, as a legal term, means the formal offer to perform some obligation incumbent on the person tendering. It is more frequently used in reference to the payment of money which is due. Whenever a tender of the debt is properly made, the legal consequence is this, that if the money is refused, the creditor will have to pay the costs of any action he may bring to recover it, and cannot claim interest afterward. In case such an action is brought, the debtor has nothing to do but to plead that he duly tendered the money, and if he then pay into court the sum which he had formerly tendered, the other party must stop the action, or continue it at his own risk. In order, however, that a tender should have the above effect, it must have been duly made—that is to say, it must have been made without imposing any conditions on the creditor, and at the proper time and place. The tender must be in money, and not by bill of exchange; but Bank of England notes are a good tender for all sums above £5. If the debt is beyond 40s., it ought to be in gold, so far as it goes. Though other bank notes than Bank of England notes are often tendered, the creditor is not bound to accept them; but if he take them without any specific objection, then it will be a sufficient discharge. A tender of a larger sum than is due is good, but must not require change to be given, which the creditor is not obliged to find. Nor must any condition be annexed to the tender, not even the condition of giving a stamped receipt, though on other grounds, by statute, a person receiving payment is bound to fill up a stamped receipt on its being tendered to him, and to pay the stamp; and his refusal to fill up the receipt subjects him to a penalty of £10. A tender of payment must, in general, be made to the creditor at the place he has indicated, and it is the duty of the debtor to find out and pay the creditor. With regard to payment of rent, however, it is enough that the tenant be ready to pay the rent on the premises at the time it is due, it being the landlord's duty to send or call for it, for the land is the proper debtor, and that is the place to apply to in the first instance.

TENDER, in naval language, a small vessel appointed for the service of a larger one. Steam gunboats are most commonly employed as tenders.

TEN DON is a term employed in anatomy to designate the white fibrous tissue reaching from the end of a muscle to bone or some other structure which is to serve as a fixed attachment for it, or which it is intended to move. In accordance with their form, tendons have been divided into the three following varieties: (1) *Funicular*, or rope-like, as the long tendon of the biceps muscle of the arm; (2) *Fascicular*, as the short tendon of that muscle, and as the great majority of tendons generally; and (3) *Aponeurotic*, or tendinous expansions, sometimes of considerable extent, and serviceable in strengthening the walls of cavities, as, for example, the tendons of the abdominal muscles.

The tendons commence by separate fascicles from the end of each muscular fiber,

and they similarly terminate by separate fascicles in distinct depressions in the bones, besides being closely incorporated with the periosteum. In some birds, whose tendons are black, the periosteum is black also, from this incorporation. If a tendon is ruptured by an accident, or divided by the surgeon, the two ends, if not too far separated, unite with extreme readiness, by the formation of intervening plastic material, which soon acquires great firmness. So rapidly is this process of repair carried on, that, according to Mr. Paget, a specimen, six days after division, could bear the weight of 25 lbs.; while in another specimen, the new material, at the end of 21 days, bore a weight of 56 lbs. When the interval between the two ends of a tendon exceeds a certain limit, there will be only an imperfect bond of union, and either a partial or total loss of the use of the muscle will result. For details regarding this process of repair, which has an intimate bearing on the treatment of ruptured tendons, the reader is referred to Mr. Paget's admirable *Lectures on Surgical Pathology*.

Among the diseases of tendons, inflammation requires especial notice. "Tendons," says Mr. Tatum, in his article upon *Affections of the Muscular System*, "together with their sheaths, are not unfrequently inflamed. Independently of gout and rheumatism, the most frequent cause is a sprain or wrench in the neighborhood of a joint. These injuries are occasionally productive of long-continued wearing pains, assuming much of a rheumatic character, and yield often slowly and unwillingly to the remedies, both local and general, employed in rheumatism."—Holmes's *System of Surgery*, vol. iii, p. 544. In one of the forms of whitlow (q.v.), known as *paronychia gravis*, or *tendinous whitlow*, "the tendons and their sheaths in the finger and hand are the seat of a severe and often most destructive inflammation, which, though often confined to one finger, not unfrequently extends to the hand and arm, attacking not only the tendons and softer parts, but exposing the bones, and disorganizing the joints."—*Op. cit.*, p. 544. It arises from slight punctures or wounds, with or without the inoculation of irritant or poisonous matter, and often without any apparent cause, except a derangement of the general health. It begins with severe and throbbing pain in the palmar surface of a finger, which extends upward along the arm. There is extreme tenderness, and a certain amount of redness and swelling, with great tenseness of the parts. If the inflammation is not checked, suppuration soon ensues, accompanied by much constitutional disturbance. The matter frequently extends among the muscles, and in bad cases occurring in unhealthy persons, the bones and joints became affected in the way already mentioned. In the early stage, free leeching, followed by hot fomentations, may be useful. The hand should be kept elevated, and an active purgative, with low diet, prescribed. If, as is often the case, these measures are unsuccessful, a free incision must be made along the center of the palmar aspect of the finger—an operation which gives extreme relief, by removing the tension, and allowing the escape of blood, even if little or no pus is discharged. A generous diet, stimulants, and tonics, are now advisable; and under this treatment the disease generally yields; although cases occasionally present themselves in which the suppuration produces such results as to render amputation of the arm necessary, or even to cause death. A permanently bent finger, from adhesion of the tendon to its sheath, is a common result in severe cases of whitlow of this kind.

Tendons are not very unfrequently the seat of syphilitic enlargements or tumors. Malignant tumors scarcely ever spring from tendons, but fibrous tumors and small cartilaginous enlargements are often found in tendons.

Rupture of the tendons is an accident which is frequently caused by violent muscular action, especially if, from illness or other causes, the muscles have been for some time in a state of inactivity. The long tendon of the biceps cubiti is very obnoxious to this injury, which, in this case, is more often due to the disorganization caused by chronic rheumatic gout than to mere mechanical violence. The other tendons most frequently ruptured are the tendo Achillis, and the tendons of the rectus femoris and the triceps humeri. When a tendon is ruptured or divided by a surgical operation (tenotomy), "the part which is attached to the muscle is drawn away from the opposite end for about an inch. Blood is poured out between the ends, but much less than in rupture of muscles. The pain is said not to be very great; a considerable shock, however, is felt, as from a blow received on the part, accompanied by cramp of the muscle, and a perfect inability to use the limb; and in rupture of the tendo Achillis, a feeling is described as if the heel were sinking into a hole in the floor."—Holmes's *System of Surgery*, vol. iii, p. 541. The essential point in the treatment of ruptured tendon is to keep the injured part in a state of constant rest and muscular relaxation, so that the separated ends may be approximated as much as possible, and to prevent any violent extension till firm union, by the process of reparation, has been established. The special methods of treating individual cases (as rupture of the tendons of the rectus femoris and the triceps, and of the tendo Achillis) are discussed in Holmes's *System of Surgery*, and other standard works on surgery.

TENE BRIO. See MEAL-WORM.

TENEDOS (Turk. *Bogdsha-Adassi*), an island belonging to Turkey in the n.e. of the Ægean sea, off the coast of the Troad, and about 17 m. s. of the western entrance to the strait of the Dardanelles. It is about 5 m. long by 2 broad, rocky, but not unproductive, with a pop. of more than 6,000, who are partly Greeks and partly Turks. The

chief t., also Tenedos, or *Bogdsha*, has a trade in wine. Opposite Tenedos, on the coast of Asia Minor, is the bay of Besika, whither the English fleet was sent in 1877.

TENEMENT, in the strict legal sense, includes everything of a permanent nature that may be an object of tenure, whether corporeal or incorporeal. The phrase *liberum tenementum*, or freehold, is thus applicable to officers and rents as well as to real estate. The term tenement took its origin in the feudal system, where all lands were held on condition of pecuniary or military service to a feudal lord; and the real estate or incorporeal hereditament became known as the *holding*, or *tenement*. The common use of the word to denote leased or rented houses is derived from the fact that such property was always occupied by tenants rather than by owners in fee. It is now very generally used to indicate rooms let within a building devoted to that purpose.

TENERA'NI, PIETRO, 1789-1869; studied sculpture with Thorwaldsen and Canova at Rome. Among his more famous works are the "Angel of the Last Judgment," the sarcophagus of Pius VIII. for St. Peter's; "Christ on the Cross," at St. Stephen's in Pisa; and "Flora," now owned by queen Victoria. He also made many statues and busts. He was professor at the academy of St. Luke, and in 1860 director of Roman museums.

TENERIFFE, the largest of the Canaries (q.v.).

TENERIFFE, PEAK OF, or PICO DE TEYDE, a famous dormant volcano, the highest summit in the Canary islands, stands in the s.w. of the island of its own name, and is 12,182 ft. above sea-level. The lower slopes of the mountain are covered with forests, or laid out in extensive meadows, yielding rich grass; but the upper ridges, and the peak, properly so called, are wild, barren, and rugged in appearance. The peak and its two inferior neighbors—the *Montana Blanco* and *Chojorra*—rise from a rugged circular plain of lava debris and pumice, 7,000 ft. above sea-level, about 8 m. in diameter, and fenced in on all sides by an almost perpendicular wall of rock. From the crevices of these mountains sulphurous vapors are constantly exhaling. The peak can be seen from a distance of upward of 100 m.; but the view from it is generally destroyed by the dense masses of cloud which hang over the surrounding sea at an average elevation of 4,000 to 5,000 ft., the sky above being almost uniformly clear and bright. Mr. Piazza Smyth, in the summer and autumn of 1856, made here a series of experiments for the purpose of ascertaining how far astronomical observation could be improved by eliminating the lower third part of the atmosphere, and with this object observed for two months, first on Guajara (an elevated peak of the rocky wall, 8,903 ft. high), and afterward on Alta-Vista (on the side of the peak, 10,702 ft. high). See *Teneriff*, by C. Piazza Smyth (London 1858).

TENES, a rising sea-port of Algeria, 100 m. w. of the city of Algiers. It is happily situated for commerce, is the entrepôt for Orleansville, and the depot for the supply of the army with provisions. It is at once fortunate in the agricultural resources of its territory, in its mineral wealth, and its position in respect to transit-trade. Pop. (of commune in 1871), 8,000.

TENESMUS (from the Gr. *teinein*, to strain), is the term employed in medicine to designate a straining and painful effort to relieve the bowels when no fecal matter is present in the rectum; the effort being excited by some adjacent source of irritation. All that is got rid of by the straining, which usually occasions more or less descent of the gut, is mucus, frequently stained with blood. Tenesmus is a common symptom in dysentery, irritation of the bladder, stricture of the urethra, etc.

TENIERS, DAVID, the elder, a Flemish artist of note, was born at Antwerp in 1582. For some years he was a pupil of Reubens; afterward, he visited Italy, where he studied under Adam Elzheimer, and, on his return, settled in his native city, where he died in 1649. The subjects of Teniers's pencil are, in general, very homely, and often low—the interiors and exteriors of public-houses, smoking-rooms, rustic games, weddings, etc.; but they are executed in the most vividly realistic manner, with such charm of color, and happy ease of composition, that they never fail to excite in the beholder a lively sense of pleasure. Teniers was almost constantly employed during his career as an artist.

TENIERS, DAVID, the younger, son of the preceding, was born at Antwerp in 1610. He received his first lessons in art from his father, who, it is said, subsequently placed him in the studio of Adrian Brauwer; but this statement can scarcely be true, for Brauwer (q.v.) was only two years older than himself. It is probable that he derived most, if not all his professional instruction from his father, to whose genius his own bore a peculiarly filial resemblance. In fact, the elder Teniers may be considered the founder of a school of which the younger is the most brilliant and prolific member. The latter, like his parent, rapidly rose into distinguished consideration, enjoying in the course of his life the favor and friendship of the archduke Leopold, queen Christina of Sweden, Don John of Austria, the prince of Orange, the bishop of Ghent, and other dignitaries. Teniers lived for the most part in a villa on the out-skirts of Malines, where he had abundant opportunities of studying closely that humble rustic life which he has so charmingly depicted in all its aspects; but he died at Brussels Feb. 11, 1685. He was twice married—first, to a daughter of the painter Breughel (q.v.), *Velut* Breughel as he was called; and again to the daughter of a councillor at the court of Brabant. The

number of his pictures is something marvelous. Smith, in his *Catalogue Raisonné*, has carefully described 685. England is peculiarly rich in specimens, but they are also literally scattered over the galleries and private collections of the continent, and, in spite of their number, bring great prices. They possess, but in a superlative degree, the beauties of the elder Teniers's pieces. In the coloring of his skies, the sketching of his trees, the animation and grouping of his figures, we see everywhere the presence of a richer, finer, more observant and more imaginative genius.

TENNANT, WILLIAM, still to be remembered as the author of *Anster Fair*, was born at Anstruther, in Fife, in the year 1785. A cripple almost from his birth, and doomed to propel himself through life on crutches, he betook himself naturally to study, as requiring no exertion of the limbs. In 1799 he went to the neighboring university of St. Andrews where, however, he only remained two years, leaving it to join his brother, a corn-agent, in business. In this his success was indifferent; and in 1813 he was fain to accept the situation of parish school-master at Denino, a small hamlet about 4 m. from St. Andrews, with a salary of £40 a year. The year before, he had published his *Anster Fair*, a poem of much sprightliness and humor, notable as the first attempt to naturalize in our language the gay *ottava rima* of the Italians; by Byron, soon after adopted with such splendid success in his *Byppo* and *Don Juan*. The piece gradually made its way, and in 1814 a highly laudatory notice of it appeared in the *Edinburgh Review*, from the pen of the then omnipotent Jeffrey. In 1816 Mr. Tennant became teacher of a school at Lasswade, near Edinburgh, whence three years afterward, he transferred his services to the academy of Dollar in Clackmannanshire. His attainments as a linguist were extraordinary; and in 1835 he was appointed professor of oriental languages in the university of St. Andrews—a post for which, perhaps, not many men then living had similar qualifications. In connection with his new duties, he published, in 1840, grammars of the Syrian and Chaldee languages. He died Feb. 15, 1848, at his residence near Dollar, where his summers were usually spent. He was one of the most genial and amiable of men. Besides other miscellanies in verse, he gave to the world, in 1822, *The Thane of Fife, a Poem*; in 1823, *Cardinal Beaton, a Tragedy*; and in 1825, *John Balfour, a Drama*. None of these later productions had much success, or did anything to increase the literary reputation which his first work had won for him.

TENNENT, GILBERT, 1703-64; b. Ireland; came to America with his father, 1718, and aided him in an academy in Philadelphia; studied medicine and theology; was ordained pastor of a Presbyterian church in New Brunswick, N. J., 1726, continuing the connection until 1743, though traveling and preaching with Whitefield in New England for several months; founded and became pastor of a church in Philadelphia, with which he remained connected until his death. In 1851 he visited England with president Davies to obtain aid for the college of New Jersey. He published *Lawfulness of Defensive War; Sermons on Important Subjects*.

TENNENT, SIR JAMES EMERSON, LL.D., 1804-69; b. Ireland; educated at Trinity college, Dublin, and called to the bar. He was a member of parliament, 1832-45; secretary to the India board, 1841-45; and civil secretary to the Ceylon colonial government, 1845-50. He was again elected to parliament in 1852, was secretary of the poor law board the same year, and a joint secretary of the board of trade, 1852-67, when he was made a baronet. Under his original name of Emerson (Tennent being added on his coming into the estates of his wife, a daughter of William Tennent), he published *Travels in Greece* (1825); *Letters from the Aegean* (1829); and *History of Modern Greece* (1839-45). Among his later works are *Christianity in Ceylon* (1850); *Account of Ceylon* (1859); *Sketches of the Natural History of Ceylon* (1861); and *The Story of the Guns* (1864).

TENNENT, WILLIAM, D.D., 1705-77; b. Ireland; brother of Gilbert; came to America, 1718. While studying theology he was attacked with fever, and fell into a trance, giving no sign of life, except a slight tremor under the left arm, which led the physician to refuse consent to his interment, and the funeral was postponed for three days, when vitality became perceptible. His recovery was slow and painful, for months his memory and mental faculties seemed lost. At length he felt a sudden shock in his head, and by degrees recovered his recollection. He related that at the time of his apparent death he found himself in the midst of wonderful glory, among a multitude singing very sweetly, and that when about to join them some one said to him, "You must go back." At the shock of this announcement he awoke. He was ordained in Freehold, N. J., 1733, and continued the pastor 44 years. He published a few sermons.

TENNESSEE, a river of the United States, the largest tributary of the Ohio, has its origin in the union of the Clinch and Holston, which rise in the Alleghany mountains of south-western Virginia, and, flowing s.w. in two parallel valleys, unite at Kingston in the w. of Tennessee state. The river flows still s.w. in the Alleghany valley, entering Alabama close by the n.w. corner of Georgia, whence it flows 60 miles further in the same course, then, turning to the w.n.w., re-enters Tennessee at the n.e. corner of Mississippi, flows northwardly across the state, then n.w. across Kentucky to its confluence with the Ohio at Paducah; length 800 miles, or, from the source of the Holston, 1100. Its chief branches are the Sequatchie, Paint Rock, Flint, Duck, North Branch, Hiawasse, Big Sandy,

and Clark's. It is navigable 259 miles to Mussel shoals—a series of broad shallow rapids—and 500 miles above. Chief towns, Florence and Decatur in Alabama; and Chattanooga, Tennessee.

TENNESSEE, a southern state of the American union, the third admitted under the federal constitution, extends in lat. 35° to $36^{\circ} 30'$ n., and long. $81^{\circ} 37'$ to $90^{\circ} 25'$ w.; and is bounded on the n. by Kentucky and Virginia; and on the s. by Georgia, Alabama, and Mississippi. Area, 45,600 sq. miles. The chief towns are Nashville (the capital), Memphis, Knoxville, Chattanooga, Murfreesborough, and Jackson. The principal rivers are—the Mississippi, forming the boundary on the w.; the Cumberland (q.v.), the Tennessee river, which twice crosses the state; the Obion, Hatchee, and numerous branches of the larger rivers, which give navigation and water-power to the entire state. Eastern Tennessee is crossed by several ridges of the Alleghany mountains, some of which have elevations of 2,000 ft.; the middle region between the Cumberland and Tennessee rivers is hilly, and the w. level. The western portion of the state, between the Mississippi and the Tennessee, is of the alluvial and cretaceous formation of the shores of the Atlantic and gulf of Mexico. Extensive iron mines lie between the Tennessee and Cumberland rivers. In the limestone regions are numerous caves, mostly unexplored. Several in the Cumberland mountains are 100 ft. deep, and miles in extent. A considerable river has been discovered in one at a depth of 400 ft.; another opening perpendicularly in a mountain has never been fathomed. In some of these caves are large deposits of fossil bones of extinct animals. In the Enchanted mountain are seen impressions of the feet of men and animals in limestone. Tracts of several acres have sunk into caverns 100 ft. deep. In many places are interesting remains of ancient mounds and fortifications.

The climate of Tennessee is temperate, and, except in some of the river-bottoms, salubrious. The soil of the whole state, except the eastern mountainous regions, is extremely fertile, producing cotton, tobacco, Indian corn, wheat, flgs, peaches, grapes, and all the fruits and productions of the southern temperate regions. The state is richly wooded with pine, oak, hickory, sugar-maple, cedar, black walnut; and the woods abound in game, as bears, deer, opossums, racoons, foxes, etc.; and the country is rich in horses, cattle, sheep, and swine—the last running in large herds in the woods, and fattening on nuts. In 1870 farms averaging 166 acres in size occupied 19,581,214 acres of land, of which 6,843,278 were improved. In the same year the live stock was valued at \$55,064,075; and the crops consisted in part of 41,343,614 bushels Indian corn, 6,183,916 bushels wheat, 21,465,452 lbs. tobacco, and 181,842 bales cotton. The commerce of the state, by its rivers and 23 lines of railway, is chiefly with New Orleans, St. Louis, and Cincinnati. There are state asylums for deaf and dumb at Knoxville, and for the insane and blind at Nashville. There are 51 colleges; a common school-fund of \$2,500,000; 2,842 churches, chiefly Methodist, Baptist, and Pre-byterian; 9 daily, 110 weekly papers. The value of property in 1874 was \$289,533,656; the bonded debt, \$22,968,400.

In 1756 a settlement was formed near Knoxville, then a part of North Carolina. Nashville was settled near the close of the revolution; and in 1790 Tennessee was organized as a territory with Kentucky; and admitted, in 1796, into the union as a separate state. In Jan., 1861, a proposal to secede from the union was defeated; but in June, carried by a majority of 57,667. In ten months the state raised 59 regiments for the confederacy; while 5 or 6 were also recruited for the union. The state was the scene, at Knoxville and Chattanooga, of some of the most important operations of the war. Tennessee sends 8 representatives to congress, in addition to the 2 senators allowed to each state. For some years after the civil war portions of Tennessee continued in a very disturbed condition, numerous outrages being committed by bands of disguised marauders. The pop. in 1800 was 105,602; 1820, 422,813; 1840, 829,210; 1860, 1,109,847; 1870, 1,258,373 (of whom 936,119 were white, and 322,331 colored).

TENNESSEE (*ante*) for civil purposes is divided into east, west, and middle Tennessee, and comprises 8 great natural divisions. On its eastern borders rises, in huge, ridge-like masses and treeless domes, the Appalachian chain, the loftiest peaks of which attain an elevation of more than 6,000 ft. above the sea. These mountains are called the Unakas, and they form one of the natural divisions of the state. Adjoining this chain on the w., and inclosed between the Unakas and what is known as the Cumberland table-land, is the valley of East Tennessee, which is one of the most important agricultural regions. Next comes the Cumberland table-land, an elevated plateau 2,000 ft. above the sea and 1000 ft. above the valley of east Tennessee. Then, resting against the western edge of the Cumberland table-land and extending to the Tennessee river, with an average elevation of 1000 ft. above the sea, are the highlands, rimlands, or terrace lands. In the center of these is the great central basin, elliptical in shape, and resembling the bed of a drained lake. Its soil is productive of all the crops suited to the latitude, and it is called sometimes the garden of the state. The western valley forms the sixth natural division, which is comparatively narrow, with spurs from the highlands pointing in toward it and here and there running down to the margin of the Tennessee river. The seventh division is a plateau or slope of west Tennessee, and differs from all the others in having only a few rocks. Its soil is light, porous, siliceous, and very fertile. The eighth division is the bottom of the Mississippi, a low, flat, allu-

vial plain, which has a rank luxuriance of vegetable life that is almost tropical. The eastern mountain-border consists mainly of silurian rocks, and in part is believed to be of the azoic age. It affords asbestos, kaolin, and red, green, and other granites. Valuable copper mines are also found in this region, and the foot hills abound in iron ore, including rich pyrites, limonite, hematite, magnetite, and iron-manganese ores. In the valley of east Tennessee are lithographic shale, heavy-spar, millstone, slate, potter's clay, limestone, native blue vitriol, marble, and ores of lead and zinc. Coal-measures occupy about 5,100 sq.m., mainly occupying the Cumberland mountain plateau, from which an annual product of 400,000 tons is usually derived. Middle Tennessee contains petroleum, alum, gypsum, glass-sand, marble, copperas, fectile clay, and iron. In west Tennessee lignite is found in abundance, and there are beds of green-sand marl. The forests of the state have a large variety of timber-trees. In the east the white and other pines grow across extensive tracts; in the west the larch, cypress, and cottonwood, and nearly everywhere may be found the tulip-tree, hickory, magnolia, sweet and black gum, black and white walnut, cherry, pecan, ash, maple, locust, beech, and several kinds of oak. The general elevation of the state secures it from the oppressive summer heat of the Gulf states, and the winters are in no parts severe. Along a line running e. and w. through the middle of the state the mean temperature is 57° in east Tennessee, 58° in middle, and 59° in west Tennessee. On the southern boundary it is about 1° higher, and on the northern 1° lower. The only sickly region is the swampy part.

The name of the state is derived from Tannassce, the Indian name of the Little Tennessee river. It was permanently colonized in 1754 by settlers from North Carolina, of which province the present state was a part. In 1776, however, it was officially designated the District of Washington; and after the revolution, the people having expressed dissatisfaction with the government of North Carolina, the whole region was ceded to the United States and became an organized territory. In June, 1796, it was admitted into the Union as a state with its capital at Knoxville. At that time there were no settlements in west Tennessee and only a few scattered here and there in middle Tennessee. But the westward tendency of emigration soon led to encroachment on portions occupied by Indians, who were finally removed to the Indian territory in 1819, from which time the growth of the state was rapid. During the rebellion, 1861-65, nearly the whole state was a battle ground. Severe battles took place at fort Pillow, Stone river, Island No. 10, Nashville, Chickamauga, Lookout mountain, Missionary ridge, Knoxville, Franklin, and other places. In April, 1865, the state legislature met in Nashville, ratified the thirteenth amendment to the federal constitution, and reorganized the state government, and the following year the state was readmitted to the union. Though it has been politically disturbed at times since, the state has, for the most part, succeeded well in returning to its former prosperity. In 1870 there were 267,020 persons engaged in agricultural pursuits; 54,396 in professional; 17,510 in trade and transportation, and 29,061 in manufactures and in mechanical and mining industries. By the census of 1880 the total population was 1,542,463, of which 1,139,120 were white, and 403,343 colored.

In agricultural products Tennessee has always ranked high. Its average annual production of Indian corn is about 50,000,000 bushels; of wheat, 8,000,000 bushels; oats, 5,600,000 bushels; tobacco, from 13,000 to 22,000 hogsheads; cotton, 400,000 bales; hay, 110,000 tons; sweet-potatoes, 1,200,000 bushels; Irish potatoes, 1,122,000 bushels; peanuts, 500,000 bushels. There are raised in particular localities hemp, broom-corn, flax, sorghum, and rice; and all the garden vegetables in nearly all parts of the state are raised in abundance. Though the number of acres devoted to barley is very small, it is nevertheless reported to be a profitable product. Rye and buckwheat, however, are not. The dairy products in 1870 were 9,571,069 lbs. of butter; 142,240 lbs. of cheese; and 415,786 galls. of milk. The live stock at that time was valued at \$55,084,075, and consisted of 273,200 horses, 102,983 mules and asses, 682,318 neat cattle (of which 243,197 were milch cows), 826,783 sheep, and 1,828,690 swine. The manufacturing industries of the state in 1870 were increasing rapidly. The number of establishments at that time was 5,317, employing 732 steam engines and 1340 water-wheels, 19,412 hands, and capital amounting to \$15,595,295. The amount of wages paid was \$5,390,630; value of raw material used, \$19,657,027; value of products, \$34,262,636. Among these manufactures were 216 flouring-mills, producing \$5,666,698 worth of flour and meal; 349 saw and planing-mills and sash factories, producing together, \$3,768,976 worth of manufactured lumber; 65 furnaces, blast-furnaces, and foundries, producing \$2,072,040 worth of iron; 395 establishments for tanning and currying leather; 28 cotton mills; 220 wheel-wright shops; 2 copper-milling and smelting works, producing copper valued at \$510,677; 133 wool-carding and dressing mills; 4 cotton-seed oil mills; 44 liquor distilleries; 89 cabinet shops; 21 machine shops; and 4 car-shops. The state has no direct foreign commerce, though Memphis and Nashville are both river-ports of entry. Its large exports of cotton are made through New Orleans, Norfolk, Charleston, and New York. The shipments of cotton (two-thirds of it from Memphis) in 1873 were 613,750 bales, and in 1872, 548,913 bales, the value of which was from 35 to 45 million dollars. The tobacco shipped annually is usually worth two millions more; and altogether the wholesale trade of the state is estimated at \$300,000,000. The amount of transportation, therefore, over the railroads is large. The most important of these roads are the Mobile and Ohio, the

Mississippi Central and New Orleans, the Memphis and Charleston, the Memphis and Ohio, the Mississippi and Tennessee, the Memphis and Paducah, the East Tennessee, Virginia and Georgia, the Nashville and Chattanooga, the East Tennessee and Georgia, the Nashville and North-western, the Jackson and Birmingham, the St. Louis and South-eastern, the Jackson and Evansville, the Selma, Montgomery, and Memphis, the Memphis and Vicksburg, the Louisville, Nashville, and Great Southern, and the Cairo and Tennessee river. Of the banks in the state in 1875, 26 were national, with \$3,360,000 paid capital, \$3,116,500 bonds on deposit and \$3,061,232 circulation outstanding; 11 were state banks with a capital of \$1,442,000; and 8 were savings banks, of which 4 reported a capital of \$263,000. The insurance companies numbered 12 fire and marine and 3 life insurance companies.

Compared with the other states and territories, Tennessee ranks in area twenty-fifth, ninth in population, seventh in lands and farms, ninth in farm products, and fifth in home manufactures. The financial affairs of the state have embarrassed its government for several years. In 1870 the public debt was \$43,052,652, which has been contracted chiefly by railroad enterprises. On Jan. 1, 1880, this amount had been reduced to about \$31,560,000, which was bearing 4 per cent interest. The *ad valorem* tax at that date was \$104,194,574; the revenue received from privileges granted and minor sources, \$295,000; and the current expenses, not including the interest on the debt, \$675,750. The constitution provides that all property shall be taxed according to its value, so that the taxes shall be equal and uniform throughout the state, and that no species of property shall be taxed higher than any other of the same value. But the legislature is empowered to except from taxation property held by the state, counties, cities, or towns that is used exclusively for public or corporation purposes, and such as may be held and used for religious, charitable, scientific, or educational purposes. Accordingly, for many years full advantage has been taken of these provisions, and up to 1875 no railroad nor any other corporations, except insurance companies and a few banks, had ever paid any state tax.

The educational interests of the state until 1873 were much neglected. Though there were many higher institutions, the common schools were allowed to go without system or state aid. At that date the legislature passed a general law establishing schools and made provisions for their maintenance. The total annual income in 1876 from the permanent fund and state taxation was about \$600,000. Besides this, the public schools in various parts of the state received aid from the Peabody education fund to the amount of \$34,300. The school population in 1875 was 319,671 white children and 106,230 colored; the number of pupils enrolled was 198,085; the average attendance (16 counties not reporting), 136,118. Among the universities and colleges in Tennessee the most prominent are Vanderbilt university (M. E. south), Nashville; Fisk university (colored), Nashville; East Tennessee university, Knoxville; East Tennessee Wesleyan university (M. E.), Athens; Cumberland university (Presbyterian), Lebanon; and the university of the South (Protestant Episcopal), at Sewanee. Altogether, these schools, with a few others not mentioned, have usually about 2,800 students. The number of libraries in the state in 1870 was 3,505, with 802,112 volumes, of which 2,732, with 597,299 volumes, were private. The total number of newspapers and periodicals published is about 141, including 9 daily, 110 weekly, 17 monthly, and 1 quarterly. The religious organizations in 1870 were: Baptist, 987; Christian, 203; Congregational, 3; Protestant Episcopal, 33; Friends, 5; Jewish, 4; Lutheran, 22; Methodist, 1339; Presbyterian, 556; Roman Catholic, 21; and United Brethren in Christ, 7.

The state constitution provides that every male citizen 21 years old, who has resided in one county a year preceding an election, shall be entitled to vote. The executive power is vested in a governor, who is chosen every two years; a secretary of state, appointed by a joint vote of a general assembly every four years; a treasurer and comptroller of the treasury, appointed in the same manner every two years; an attorney-general, appointed by the supreme court judges every eight years; and a state superintendent of schools, nominated by the governor and confirmed by the senate every two years. The house of representatives has 75 members and the senate 25, who are elected for two years. The judicial power is vested in a supreme court of 5 judges, elected for 8 years, and in the usual minor courts. By the apportionment of 1870 the state is entitled to 10 representatives in congress. The state's electoral votes have been cast as follows: 1796, Jefferson and Burr, 3; 1800, Jefferson and Burr, 3; 1804, Jefferson and Clinton, 5; 1808, Madison and Clinton, 5; 1812, Madison and Gerry, 8; 1816, Monroe and Tompkins, 8; 1820, Monroe and Tompkins, 7; 1824, Jackson and Calhoun, 11; 1828, Jackson and Calhoun, 11; 1832, Jackson and Van Buren, 15; 1836, White and Tyler, 15; 1840, Harrison and Tyler, 15; 1844, Clay and Frelinghuysen, 13; 1848, Taylor and Fillmore, 13; 1852, Scott and Graham, 12; 1856, Buchanan and Breckenridge, 12; 1860, Bell and Everett, 12; 1868, Grant and Colfax, 10; 1872, Greeley and Brown, 12; 1876, Tilden and Hendricks, 12; 1880, Hancock and English, 12.

TENNEY, in heraldry, orange color, one of the tinctures enumerated by heralds, but not of frequent occurrence in coat-armor. It is indicated in engravings by lines in bend sinister, crossed by other barways.

TENNEY, SAMUEL, 1748-16; b. Mass.; graduated at Harvard, 1772; began practice as a physician in Exeter, N. H.; became a surgeon in the revolutionary army, and was present at the battles of Saratoga and Yorktown. From 1800 to 1807 he was a member of congress. He was one of the first members of the American academy of arts and sciences, and published many scientific treatises and political essays.

TENNEY, SANBORN, 1827-77; b. N. H.; educated at Amherst college, and studied natural history with Agassiz. He was for some years a lecturer on natural history, of which he became professor in Vassar college at its foundation. He was called to a similar position at Williams college in 1868. Among his publications are: *Geology for Teachers, Classes, and Private Students*; a *Manual of Geology*; *Natural History Tablets*; and *Elements of Zoology*.

TENNEY, WILLIAM JEWETT, b. Newport, R. I., 1811; graduate of Yale college, 1832: He was co-editor of the *Journal of Commerce*, of the *New York Evening Post*, and editor of the *Mining Magazine*. He became a member of a staff of writers connected with Appleton's publishing house in New York, and is one of the editors of Appleton's *Annual Cyclopaedia*. He has edited an illustrated edition of *The Queens of England*, and prepared *The Military and Naval History of the Rebellion in the United States*, 1865.

TENNIS, a game of great antiquity, belongs to the class of ball-games, and finds its analogies in the *sphairistikos* of the Greeks, and the *pila* of the Romans. Under the name of *paume*, a name given to it from the ball being at that time struck with the palm of the hand, it is noticed in the Arthurian romances, and in the earlier records of the dark ages. In the 15th c. it was in great vogue in France among all classes, from the monarch to the meanest of his subjects; and about this time the use of a heavy glove to protect the hand in striking the ball was introduced, and a further improvement was subsequently effected by the adoption of the *racket*. The game in England kept pace with its progress in France, and, during the 16th, 17th, and 18th centuries, was generally practiced under the name of *tennis*. Many modifications have been introduced, but the legitimate descendant of the *paume* and *tennis* of former days is the present game of rackets. (See LAWN TENNIS). "Rackets" is played in a court 96 or 97 ft. long, by 33 or 34 feet wide, and surrounded by walls sufficiently high to prevent the balls from being lost. The players are either two in number, or four, divided into two parties. The player or party "in" *serves* the ball against the head-wall of the court, so as to rebound over a line drawn at a certain distance; it is returned by means of the racket by the player or party "out," who must make it rebound from the wall to the other side of the line; and the game is thus carried on till one player fails to strike the ball or cause it to rebound properly. If the player "in" fails, he changes places with the player "out;" if the latter fails, the former scores a point. The part of the court on which the player or party in is placed is called the "service" side; the other the "hazard" side. A similar game played without the racket is called *fixes*, *hand-tennis*, or *hand-ball*.

TENNYSON, ALFRED, was born in the year 1809 at Somersby, in Lincolnshire, of which parish his father was rector. He was the third of a large family, several other members of which shared with him in some measure the genius which has won for him undisputed rank as the first English poet of his time. Very early the bent of nature became obvious; and in 1827 Tennyson, along with his brother Charles, issued a small volume, entitled *Poems, by Two Brothers*, of which almost nothing has been preserved. Having gone to complete his education at Trinity college, Cambridge, he gained in 1829 the chancellor's medal by a poem in blank verse, entitled *Timbuctoo*, in which there is plainly to be traced some impress of his peculiar genius. His literary career, however, may properly be said to date from 1830, in which year a volume appeared of *Poems, chiefly Lyric*, by Alfred Tennyson. It was not received with great favor by the public; but amid much that was weak and immature, it contained pieces which in no indistinct manner announced the advent of a true poet. In a notice of the book by prof. Wilson, in *Blackwood's Magazine*, the promise of the young writer was recognised in sufficiently express terms. The praise was, however, not unmixed with censure, which, though it seemed on the whole judicious, did not commend itself as such to the poet, who retaliated on "crusty Christopher" in his next volume, published in 1833. This consisted of a selection of poems from the previous one, carefully retouched by the writer, with the addition of pieces produced in the interval, many of which have scarcely been surpassed in beauty by anything he has since produced. Onward from this time the reputation of the writer slowly but surely extended itself; and the publication, in 1842, of *Poems, by Alfred Tennyson*, in two volumes, raised him to the position of absolute supremacy which he has ever since continued to occupy by almost universal consent. In 1847 appeared *The Princess, a Medley*; and in 1850 the series of elegies entitled *In Memoriam, A. H.*, a tribute of affection to the memory of Arthur Hallam, a son of the eminent historian, and the chosen friend of the poet in his earlier years at Cambridge. On the death of Wordsworth, in 1850, Tennyson succeeded him as poet-laureate, in which capacity he issued, in 1852, his *Ode on the Death of the Duke of Wellington*. In 1855 appeared *Maud, and other Poems*. The immediate reception of this little volume was not enthusiastic. While many of its lyrics instantly caught

the public ear, *Maud*, as a whole, at first rather puzzled the critics, and was little better than "caviare to the general;" and though it has since risen in estimation, the subtle and recondite art exhibited in the structure of the poem is probably even now appreciated by only a few of its admirers. But for any little falling off in Tennyson's popularity on this occasion, a noble *amende* was made him on his next appearance. *The Idylls of the King*, published in 1859, were everywhere received with enthusiasm. With scarce a whisper of dissent, this work at once took rank as one of the noblest poems in our language. It was followed in 1864 by a volume, containing *Enoch Arden*, one of his most finished and successful works; *Aylmer's Field*; a short piece, *Tithonus*, consummate in its beauty and finish; and a few other poems of a somewhat less elaborate character; one of which, however, *The Northern Farmer*, written in the Lincolnshire dialect, is singularly striking. Since then Tennyson has given us several new *Idylls*, which may be considered to complete his handling of the Arthurian romance: *The Holy Grail* and *Pelleas and Ettarre* (1869); and *Gareth and Lynette*, and *the Tournament* (1873). *The Window, or Songs of the Wrens*, appeared in 1870. In 1875 he essayed in a new field by publishing *Queen Mary*, a drama, which was followed by *Harold*, also a play, in 1876. The collected editions of Tennyson's works (since 1872) arrange the various *Idylls of the King* in the order, not of their publication, but of their proper sequence in the legend of Arthur, and enable the reader to appreciate the full beauty and significance of the ideal story. Tennyson's biography, even more than that of most authors, is given, so far as the public is concerned with it, in the simple enumeration of his works. He has lived for the most part a retired life in the Isle of Wight, not much caring to cultivate society, but greatly beloved by his intimate friends.

It is not an easy matter to criticize the poetry of Tennyson dispassionately, so deeply is one apt to become enamored of its beauties. His verse is the most faultless in our language, both as regards the music of its flow and the art displayed in the choice of words. Nowhere in literature is the *callida junctura verborum* so wondrously seen. As a painter, no modern poet has equaled him. But it is neither to his color nor to his music alone that he owes his great popularity. His *virtue* as a poet doubtless lies in these things; but the pleasure which his poetry gives springs largely from the cordial interest he displays in the life and pursuits of men, in his capacity for apprehending their higher and more beautiful aspirations, and in a certain pervasive purity and strength of spiritual feeling.

TENON, in carpentry, the square end of a timber, reduced about one-third its thickness, to fit the mortise or socket in another timber, so as to join the two.

TENOR, in music, one of the four classes into which voices are divided in respect of their compass. It is the higher description of adult male voice, and generally extends

from  to . Music for tenor voices is most properly written on the

tenor or C clef, , in which its principal tones come within the staff; but the treble clef is occasionally used, with the notes written an octave above their true pitch.

TENOTOMY, or the division of tendons, is a comparatively recent surgical operation, whose object is to relieve some variety of deformity by severing a permanently contracted muscle at its tendinous portion. The invention of subcutaneous tenotomy is due to Stromeyer (1831), and a lucid account of the history of this operation is given by Dr. Little in his *Treatise on Club-foot and Analogous Deformities* (Lond. 1839). The various kinds of knives that have been devised for severing tendons are termed *tenotomes*. The affections in which tenotomy is advantageously employed are club-foot, contractions of the upper extremity from spasm and paralysis, deformity from diseases of the palmar fascia, torticollis or wry-neck, ankylosis of the knee and other articulations, and squinting.—For further details, the reader is referred to the above-mentioned work by Dr. Little, and to the same author's treatise *On the Deformities of the Human Frame* (Lond. 1853).

TENREC, or **TANREC**, *Cenetes*, a genus of mammalia, nearly allied to moles and hedgehogs, usually ranked in the family *crinacidae*. The tenrecs are incapable of rolling themselves up like hedgehogs. They are nocturnal animals, natives of Madagascar and the Mascarene isles. Three species are known. They are remarkable for spending the hottest part of the year in a dormant state, as some animals in arctic regions spend the winter. Their flesh has a very peculiar flavor, but is acceptable to the natives of Madagascar.

TENSAS, a parish in n.e. Louisiana, lying on the Mississippi; drained by Tensas river and Macon bayou; 680 sq.m.; pop. '80, 17,824—17,654 of American birth; 16,250 colored. Surface low, level, and fertile; corn, cotton, and sweet potatoes are the staples. Capital, St. Joseph.

TENSE (Fr. *temps*, from Lat. *tempus*, time), in grammar, designates a set of changes which verbs undergo in order to mark the time of the action. See **CONJUGATION**.

TENT (Lat. *tentorium*, from *tentus*, stretched). Without speculating on the relative priority of tents and other forms of human dwellings, it is safe to assume, that among nomadic tribes, some shelter, easily framed and portable, must have been felt to be a primary necessity. The skins of animals, or the larger kinds of foliage, would form the earliest coverings, for which textile fabrics would be substituted as civilization advanced. In the book of Genesis, the patriarchs, Noah, Abraham, Lot, Isaac, Jacob, are represented as dwelling in tents, probably much the same as the modern Arab tents, which are large structures, very rude in form, covering a considerable space of ground, but of small height. Among the Nineveh sculptures is a representation of the tent of king Sennacherib, which, like modern tents, was supported by ropes: numerous tents of the officers and common people are likewise shown.

The early Greek, and afterward the Macedonian tents were small coverings of skins, under each of which two soldiers slept. Alexander the great is said to have had a pavilion of extraordinary magnificence. Its roof, one mass of gilded embroidery, was sustained by eight pillars covered with gold. In the center, was the royal throne; and 100 beds could be made up within the temporary edifice.

The Roman soldiers seem to have used two sorts of tents—one, a tent proper, of canvas or some analogous material, and constructed with two solid upright poles, and a roof-piece between them; the other, more resembling a light hut, of a wooden skeleton, covered by bark, hides, mud, straw, or any material which afforded warmth. Of these tents, the poles of the first would have been too cumbersome for carriage, and were probably cut afresh at each halting-place; the latter was evidently unsuited to removal, and was most likely only erected for winter-quarters, or a long sojourn. The Roman tent held 10 soldiers, with their *decanus*, or corporal.

In Persia, there are many tribes who pass their whole time in tents, which, naturally, they have brought to considerable perfection. They make them nearly hemispherical, with a wooden framework, and covered with felt, while worked hangings close the aperture. This felt admits of the exhibition of much taste in its decoration.

The Chinese lower orders live much in tents. They are ordinarily of matting. These people are clever in their construction, and make them of great size, and with considerable comfort.

Modern military tents are all made of linen or cotton canvas, supported by one or more poles according to shape, and held extended by pegs driven into the ground. British tents comprise the hospital-marquee, a large oblong tent with high side-walls; and the round-tent, or bell-tent, for troops. The latter is 12 ft. 6 in. in diameter, 10 ft. 4 in. high, weighing, with all its appurtenances, 68 lbs., and giving sleeping accommodation to 16 men; the appurtenances comprise 2 mallets, 50 pins, 20 ropes, 20 loops, and 2 long ropes, for use in storms in giving additional firmness round the central pole. In modern tents, there is a low side-wall of canvas, to give greater room inside. These tents are said to be comfortable and moderately healthy, if floored with tarpaulin, vulcanized india-rubber, or other waterproof material. The great drawback is the tendency to blow over. To obviate this, and the inconvenience arising from the conical shape, maj. Rhodes, a British officer, invented some years ago a new tent, which has found much favor both in this and in other countries. He does away with the central pole, and has a circular frame, hinging in the center like the ribs of an umbrella, over which the canvas is stretched. It is claimed for this tent, that it is more roomy than the regulation-tent, in proportion to its weight, is better ventilated, and possesses far greater stability.

TENTACULITES, a genus of obscure annulated tapering shells, found abundantly in some strata of silurian age. They are generally referred to annelids, but the structure of the shell seems to exhibit greater affinities to recent pteropodous mollusks.

TENTERDEN, a municipal borough and market-t. in the Weald of Kent, 18 m. s.s.e. of Maidstone. The church, which contains portions of early English, is surmounted by a massive and lofty perpendicular tower. Tradition asserts that a quantity of stones, which had been got together for the purpose of strengthening the sea-wall of the Goodwin Sands, were employed in the building of this tower, and that when the next storm came, the district of Goodwin Sands, which had formerly belonged to the mainland, was submerged. Thus arose the popular saying, that "Tenterden steeple was the cause of the Goodwin sands." Pop. '71, 3,669.

TENTERDEN, CHARLES ABBOTT, Lord, a distinguished English lawyer, was born at Canterbury, on Oct. 7, 1762. He was the son of a hairdresser. Being admitted on the foundation of the king's school connected with the cathedral, he distinguished himself by perseverance and extreme accuracy. A small exhibition in the gift of the chapter enabled him to proceed to Oxford, where, in 1781, he was elected scholar of Corpus Christi college; and a few years later he obtained what were then the chief distinctions at the university, the chancellor's two gold medals, one being for English, and the other for Latin composition. In due time he became a fellow of his college. After being a student of the Inner Temple in 1795, he was called to the bar. He joined the Oxford circuit; and in spite of a husky voice, a leaden and unmeaning countenance, and painfully timid manners, his great activity of mind, good taste, scholarship, scientific and legal knowledge, were soon appreciated, so that he rapidly acquired a large business. He

published, in 1802, his treatise *On Merchant Ships and Seamen*, in all respects the best written book which had till then appeared on one department of English law. It had the effect of increasing his employment in the more lucrative mercantile causes; and in 1807, it appears from his income-tax return that his fees amounted to upward of £8,000. In 1816 he accepted a puisne judgeship in the court of common pleas; and in 1818 he was knighted, and chosen to succeed lord Ellenborough as chief-justice of the king's bench. As a judge, his most marked characteristic was his evident impartiality and freedom from bias. The comparative leisure he enjoyed on the bench he spent in reading the classics and in the study of botany. He was, in 1827, raised to the peerage. In the house of lords he was the most influential speaker against the Catholic relief bill; and in his last speech he made a vow that if the reform bill, that "appalling bill," passed, he would never again take his seat as a peer. The success of the measure, it is believed, affected his health. He was seized with a violent attack of inflammation in Nov., 1832, when presiding at the trial of the mayor of Bristol for misconduct during the riots, and he died there on the 4th of that month.

TEN THOUSAND, RETREAT OF TIME. After the battle of Cunaxa and the death of Cyrus, in the expedition of the latter against his elder brother Artaxerxes, the Greek army being in great straits chose Xenophon as one of their leaders, and by his firmness and prudence were conducted back to Greece after enduring many hardships and fierce warfare. The story is told by Xenophon himself in his *Anabasis, or Retreat of the Ten Thousand*, (see **CYRUS** and **XENOPHON**). The entire distance, going and coming was 1155 parasangs, or over 4,000 English m., and the time occupied in the retreat was 8 months. The course was through Media, across the Carduchi range, through Armenia and across the Euphrates, and then through the countries of the Taochi, Chalybes, Macrones, and Colchians, terminating in the Greek colony of Trapezus, on the Euxine sea.

TENUROS TRÉS, a tribe or sub-order of birds, of the order *insessores*, characterized by a lengthened slender bill, which is sometimes straight, sometimes curved. Some of them feed on insects, some chiefly on the honey of flowers. To this tribe belong the creepers (*certhiadae*), sun-birds (*cinnyridae*), humming-birds (*trochilidae*), and hoopoes (*upupidae*).

TENURE OF LAND, in England, was an accompaniment or immediate consequence of the feudal system (q.v.) established during the middle ages throughout the greater part of Europe. Feuds were introduced by the barbarous tribes who poured themselves into the Roman empire during the 4th, 5th, and 6th centuries. The chief feature of feuds was, that the lands of the conquered country were parceled out to the conquerors, on the condition of bearing arms whenever the sovereign required them. The relation thus created between sovereign and vassal was called a feud. The grantee held his lands at first for life only, but gradually it was developed into a hereditary character, and also into one which admitted of subinfeudation, i.e., the parceling out of the feudal land among vassals of the head vassal, who was the lord of his own vassals. This kind of relation between lord and vassal gradually was extended to all kinds of land, for the owners of allodial land voluntarily surrendered their land to some lord, so as to have the same advantages. The vassal did homage to the lord, and took the oath of fealty. Besides these characteristics, the holding came to be attended with the following incidents. 1. An aid, which was a payment granted to help the lord in his necessities. 2. A relief was a tribute paid by a new tenant on succeeding to his predecessor. 3. A fine was paid by a tenant to the lord on alienating the lands to a purchaser. 4. An escheat or forfeiture was the reverting of the estate to the lord when there was a failure of heirs or some violation of duty on the part of the vassal. The feudal system was extended to England by the Norman barons soon after the conquest, with the concurrence of William I., much to the dislike of the Saxons, whose grievances grew until they found vent in Magna Charta, which was in fact an attempt to restore their earlier constitution. The chief fiction, however, of a relation between the crown and the holders of land was not got rid of. The crown was nominally the lord paramount, and there were intermediate lords called mesne lords, of whom the tenants held. Gradually, the kinds of tenure were classed under free and base services—the former being those which a free-man might perform, as serving in war, or paying a sum of money; the latter, such as a peasant might perform, such as ploughing the lord's land, etc. These were afterward further distinguished according to the certainty or uncertainty of the extended service to be performed. Ultimately, the tenures were classed as three, 1. *Knight-service*, or *chivalry*, i.e., holding on condition of serving in the war, and taking the oath of fealty. This was accompanied by the incidents of descent, wardship (or guardianship of the knight's heir by the lord), marriage (i.e., the lord's right to give the knight's infant in marriage), aids, reliefs, primer seisin (i.e., one year's profits from an heir on his succession), fine, escheat, and forfeiture. These incidents gradually grew irksome. James I. proposed to commute knight-service into an annual fee-farm rent; but this not being done, the statute of 12 Ch. II. c. 24 swept the whole away, and converted it into free socage. 2. *Free socage* was a tenure by some certain and determinate service, as by paying a small fixed rent, or ploughing the lord's lands for a fixed number of days. The incidents were rather less burdensome than those of knight-service, being descent, wardship, marriage,

and reliefs, primer seisin, fines, escheat, and forfeiture. These incidents were all abolished by the above statute of 12 Ch. II. c. 24, and the tenure of free socage is now generally known as freehold. 3. *Villainage service*, or copyhold tenure (q.v.), which still exists nearly in its original state. The result is, that in England at the present day the two tenures are freehold and copyhold. The leading characteristic of freehold is, that practically the feudal relation between the crown and the holder is cut off, and the holder is entirely his own lord and master, can sell the estate, devise it by will, give it away, and do what he likes with it free from any interference or payment to the crown. As to copyhold, the feudal relation is kept up to a certain extent between the lord and the copyhold tenants, who must in form pay rents more or less nominal, and fines and heroids (q.v.) to the lord on alienating the lands or succeeding thereto. Yet, practically, the copyholder does not materially differ from a freeholder except that he is liable to these petty and harassing acknowledgments toward a stranger; and by recent statutes, he can compel the lord of the manor to commute these fines and incidents, and convert the tenure into freehold.

In Ireland the tenure of land is almost identical with that in England.

As to Scotland there is a marked difference between the tenure of lands there and the tenure in England. At the present day the feudal system prevails to a great extent, resembling in many respects the English copyhold tenure. Every piece of land there has generally its lord or superior and its vassal, that is say, the vassal has the *dominium utile*, or actual enjoyment, while the superior has a kind of superior interest, or *dominium directum*, which consists in his drawing a rent called a feuduty, which the vassal is bound to pay, or to forfeit the land. On each alienation or death of the vassal, there must be certain forms superadded, implying a consent or recognition by the superior, and certain casualties or additional payments must be made on such occasions. Recent statutes have tended to extinguish several of these superfluous forms, and make the vassal more independent. But a great many remain unaltered. And not only is there this feudal relation between the crown and its vassals, but these may subdivide the property and create intermediate estates without limit, each vassal being in turn the superior to his subvassal; and this endless chain of relationships complicates the conveyancing still more. See CONVEYANCING; FEU.

TEOCALLI (House of God), the name given to the temples of the aborigines of Mexico, of which many still remain in a more or less perfect state. They were built in the form of four-sided pyramids, and consisted for the most part of two, three, or more stories or terraces, with the temple, properly so called, placed on a platform on the summit. The largest and most celebrated is the pyramid of Cholula, measuring 1440 ft. each way, and 177 in height; it is much defaced, and the temple on its summit has been removed. The teocallis in Yucatan are in far better preservation; they are not generally built in terraces, but rise at an angle of 45° to the level of the platform, with an unbroken series of steps from base to summit. The temples on their summit are sometimes ornamented with bas-reliefs in stucco and hieroglyphic tablets, and the roof is formed by courses of stone approaching each other, and furnished with projections like dormer windows. Not unlike the teocallis are the palaces of the Aztec kings or chiefs, which differ from them in having the pyramid smaller, less prominent, and oblong in plan, while the building, larger and more elaborate, consists for the most part of a stone basement, with square doorways, but without windows, surmounted by a structure which appears to be directly copied from wood-work. On some of these façades we have also rude pillars and grotesque carvings, and there are often a number of chambers in the interior. A palace and temple are sometimes found attached together; and in a few cases, the most remarkable of which is the Casa de las Monjas, at Uxmal, the buildings are arranged round a court-yard. See MEXICO.

TE'OS, an ancient Ionian city on the w. coast of Asia Minor; on a peninsula s.w. of Smyrna. It was a member of the Ionian confederacy and prosperous till the Persian conquest, when a large part of its inhabitants withdrew to Abdera in Thrace. Its principal production was wine. It was the birthplace of Anacreon, of Heecataeus, of the geographer Andron, and the sophist Protagoras.

TEPIC', a t. of Mexico, in the state of Jalisco, on a height 400 m. n.w. of the city of Mexico. Tepic is the residence, during the rainy season, of most of the wealthy inhabitants of the port of San Blas, about 25 m. distant. Pop. 10,000.

TERA MO (anc. *Interamna*), a t. of southern Italy, in the province of the same name, at the junction of the Tordina and Vezzola, 28 m. n.e. of Aquila. It is well built, with long and rather wide streets, has a cathedral, a public library, a foundling-hospital, and a botanic garden, carries on an active trade in corn, wine, and olives, and has a pop. of 10,000.

Ancient *Interamna* (of which the name Teramo is an Italianized form) was a city of Picenum, in the territory of the Præutii. In the middle ages it also bore the name of Abrutium or Aprutium (supposed to be a corruption of Præutii), whence the modern name of the district, Abruzzo. Vestiges of the ancient city—the amphitheater, temples, baths, aqueducts, etc.—are traceable, and many statues, altars, and inscriptions have also been discovered. In the plain below Teramo took place, July 27, 1460, between the army of John duke of Anjou and the Milanese allies of Ferdinand I. of Aragon,

one of the most sanguinary battles ever fought in Italy. After the contest at Casteldardo (1860), Teramo was the first Neapolitan city that opened its gates and gave joyful welcome to king Victor Emmanuel.—Pop. of province '71, 246,004.

TERAPHIM (Heb. plur.), a word of uncertain derivation (connected by some with *Serapis*), denoting certain images, idols, or household gods occurring in the Old Testament, which were consulted as oracles, and probably even worshiped to a certain extent. The gods which Rachel stole are called *teraphim*, and Saul was reproached by Samuel for stubbornness which is like *teraphim*; his daughter placed a *teraph* into David's bed to conceal his flight, etc. There is no proof that this veneration for *teraphim* was not held perfectly compatible with the worship of Jehovah, spite of some reformatory attempts to sweep them away. Many and curious have been the explanations given of the nature of the *teraphim* by different scholars in and out of the synagogue. A vague but generally prevailing notion is that of their having been a kind of astrological automata, which somehow or other could be made to move and to utter certain sounds. All that is certain, however, is only the fact that the real meaning and character of this strange idol has been forgotten already at a very early period.

TERATOLOGY (Gr. *terata*, wonders, or monsters) is a term used in physiology as synonymous with "The History of Monstrosities or Anomalous Formations." See **MONSTROSITY**.

TERBIUM, a very rare metal, whose oxide, *terbia*, is found in association with the rare earth yttria, the oxide of yttrium (q.v.).

TERBURGH, GERHARD, a Dutch painter, belonging to an old and respectable family of Zwoll, was b. in 1608; studied first under his father, who was also an artist of note, and afterward visited Germany, Italy, Spain, England, and France. On his return to his native country he settled at Deventer, of which town he became burgomaster, and died in 1681. The elegant ostentatious life of his time, with its superlative courtly manners and splendid costume, found in Terburgh an admirable painter. The central figure in many of his pictures is a young lady with fair hair and dressed in white satin. His most famous piece, however, is a picture containing portraits of the 69 plenipotentiaries who drew up the treaty of Westphalia. In Dr. Waagen's opinion, Terburgh is the real founder of the art of painting conversation-pieces, and at the same time the most eminent master in this style. "In delicacy of execution he is inferior to none, and in a certain tender fusing of the colors he excels all others; but none can be compared with him in the enchanting harmony and silvery tone, and the observance of the aerial perspective. His figures, which are well drawn, have an uncommon ease of refinement, and are frequently very graceful." Terburgh's works are to be found in various English collections, particularly those of sir Robert Peel, the duke of Sutherland, lord Ashburton, Mr. Hope, the marquis of Bute, and her majesty; as also in the galleries of Dresden, Munich, Vienna, the Louvre, Amsterdam, and Berlin.

TERCE (Lat. *tertia*, i.e., *hora*, the third hour), one of the "lesser hours" of the Roman breviary, so called from the time of the day for which it is fixed. See **CANONICAL HOURS**.

TERCE, in the law of Scotland, is the interest or estate which a widow has in the land of her deceased husband at common law. This amounts to a life rent of one-third of such estates. In estimating the estate of the husband all real burdens must be first deducted, and certain other things—as the mansion-house, if there is only one, superiorities and patronage, leases and feu-duties. The mode by which a widow completes her title to the *terce* is by a process called *kenning to the terce* (q.v.), the object of which is to separate her portion from the rest, which goes to the heir, so that each may possess independently his and her portion respectively. She is then in the position of an ordinary proprietor for life. Though *terce* is a legal right, yet this right of the widow may be modified by an ante-nuptial contract, under which she is otherwise provided for.—In England and Ireland a widow has a similar right, called *dower* (q.v.).

TERCEI RA, one of the Azores islands (q.v.), and the second in size of that group, forms one of the central cluster, and lies eastward from San Jorge. Area, 220 sq.m.; pop. between 40,000 and 50,000. Steep rocks of lava almost everywhere line the coast—the island is accessible only at few places, and these are defended against invasion by fortifications. The soil is fertile: the plateaux of the mountains afford excellent pastures, and cattle breeding is an important branch of industry: the principal articles of export are wine, timber, and orchil. Chief town of the island, Angra, the capital (pop. 18,000), in the fort of which reside the governor and the bishop of the Azores.

TEREBINTACEÆ. See **ANACARDIACEÆ**.

TEREBRANTIA, a section of the insect order *hymenoptera*, distinguished by the females having an ovipositor. To this section belong sawflies (*tenthredinida*), ichneumons, gall-insects, etc.

TEREBRATULA, a genus of deep-sea brachiopodous mollusca. The animal is attached to the shell by a pedicel, and the brachial disk is three-lobed, the center lobe being elongated and spirally convoluted. The shell is smooth, with a truncated perforated beak, the foramen being circular. The shelly loop is very short and simple.

The shell of this genus, and some of its allies, is covered with minute quincuncial perforations, sometimes visible to the naked eye, but usually requiring a lens of a low power to distinguish them. The generic title is now restricted to shells with a short internal loop. The species with long loops are grouped together under the name *Waldheimia*. Of the restricted genus, there is only a single living species (*terebratulă vitrea*); but the fossil species are more than a hundred in number, and are found in all periods of the earth's history, from the Devonian age upward.

TEREDO, a genus of lamellibranchiate mollusks of the family *pholadidæ*; very much elongated, and worm-shaped; the mouth very delicate, open in front and at its lower part, for the passage of the short foot; the shell rather thick, equivalve, destitute of hinge, gaping at both ends. The species are rather numerous, and are generally known by the name of *Shipworm* or *Pileworm*, because they perforate and live in timber. Their perforations are made in the direction of the grain of the timber, except when a knot is met with or the shell of another *teredo*, when they accommodate themselves to circumstances by bending. The cavity is lined with a calcareous incrustation. The aperture by which the teredo enters is small, and it grows within the cavity which it makes. Two small valves form the true bivalve shell; the calcareous tube incloses the worm-shaped body of the animal. Its growth is very rapid, and its ravages are often terrible. A piece of deal has been found riddled by shipworms after forty days' immersion. Ships, piles, and all submarine woodwork are destroyed by it. Copper-sheathing is employed to protect ships from the shipworm, or the timber is driven full of short, broad-headed nails, the rusting of which forms a coating which it does not penetrate. The dykes of Holland have been threatened with destruction by its ravages. The COMMON SHIPWORM (*teredo navalis*) is said to have been introduced into Europe from warmer climates. It is now, however, extremely abundant in European seas. In the East Indies, a very large species (*teredo gigantea*) is found, generally in shallow water among mangrove trees; it is sometimes more than five feet in length, and at the thickest part three inches in diameter.

TEREK, one of the most considerable streams of the Caucasus, rises near the lofty mount Kasbec (about 17,000 ft. high), flows n.w. through the defiles of the mountains, crossing the district of the Kabarda, and reaches the border of the government of Stavropol, where it curves eastward, forming the s. boundary of that government, until, reaching Kisliar, it divides into numerous branches, which form a delta 70 miles broad, and 50 miles long from apex to base, and falls into the Caspian sea. It is not navigable. Total length estimated at from 300 to 390 miles.

TERENTIUS A FER, PUBLIUS, the comic poet, was born at Carthage, 195 B.C. By birth or purchase, he became the slave of the Roman senator Publius Terentius Lucanus, who, out of regard to his handsome person and unusual talents, educated him highly, and finally manumitted him. On his manumission, he assumed, of course, his patron's *nomen*, Terentius. His first play was the *Andria*, written in his 27th year, but not acted till 166 B.C. Its success was immediate, and introduced its author to the most refined society of Rome, where his engaging address and accomplishments made him a particular favorite. His chief patrons were Lælius and the younger Scipio, after living with whom in great intimacy for some years in Rome, he went to Greece, where he translated 108 of Menander's comedies. He never returned; and the accounts of how he came by his death are conflicting. He is supposed to have died in his 36th or 37th year, leaving one daughter. Six comedies are extant under the name of Terentius, which are, perhaps, all he produced—viz., *Andria*, *Hecyra*, *Heautontimorumenos*, *Eunuchus*, *Phormio*, and *Adelphi*. In conjunction with Plautus, Terentius, on the revival of letters, was studied as a model by the most accomplished play-writers. His language is pure almost to being immaculate, and though inferior to Plautus in comic power, he is more than his match in consistency of plot and character, in tenderness, in wit, and in metrical skill. His plays have an educational value, as dividing, with the works of Cicero and Cæsar, the honor of being written in the purest Latin. They have been translated into most of the European languages. The best editions of his works are those of Bentley (Cambridge, 1726), and of Parry (1857).

TERESA, SAINT, one of the most remarkable of the female saints of the modern Roman calendar, and the most admired of the modern mystic writers of that communion, born at Avila, in Old Castile, March 28, 1515, was the daughter of Alfonso, of the noble house of Sanchez de Ceyeda. Even as a child, Teresa was remarkable for piety of a most enthusiastic kind; and when she was but seven years old, she and her little brother, Rodrigo, fled from her father's house, with the design of offering themselves for the crown of martyrdom among the Moors, but were overtaken and restored to their parents. Her mother died while she was still young, and she was educated in a convent at Avila, from which, however, she was compelled by illness to return home when she was in her 16th year. During her illness, she resolved, notwithstanding the very earnest opposition of her father, to become a nun, and having in her 18th year entered a convent of the Carmelite order in her native city, she made her solemn vow on the 3d of November, 1534. In this convent she continued to reside for nearly thirty years, but it was not until about the year 1539 that her constitution became strong enough to permit her to follow, even in an imperfect way, the observances of conventual life. Her own

account of her mental and spiritual condition during this period, which extended to the year 1555, is extremely interesting, and, like the confession of St. Augustine, and other saints, has furnished endless materials to the spiritualists of more recent times. The change of heart and of purpose came in 1555-1556, and was as complete and decisive as her former condition had been purposeless or fluctuating. After a time her religious exercises reached a most extraordinary degree of asceticism. Her prayers were almost continual, and she was reported to be favored with visions, ecstasies, and other supernatural visitations, of which many curious details are related by her biographers, and in her own letters and papers. The fame of her sanctity spread not only throughout Spain, but into almost every part of the church. By some, the reality of the reported supernatural favors which were ascribed to her were called into question; and there were even some who threatened to invoke the rigorous investigation of the holy office; but the popular voice was freely accorded to her, and the authority of St. Francis Borgia, St. Peter of Alcantara, and other high names eventually disarmed the opposition. The most notable and permanent fruit of the enthusiastic spirituality of Teresa is the reform of the Carmelite order, of which she became the instrument. She commenced this work in concert with a few zealous members of her own sisterhood in the convent at Avila, where she had resided from the date of her profession; but after a time, she obtained permission from the holy see, under the direction of Peter of Alcantara, to remove with her little community to St. Joseph's, a small and very humble convent in the same city, where she established in its full rigor the ancient Carmelite rule, as approved by Innocent IV. in 1247, with some additional observances introduced by Teresa herself. This new convent was established in 1562, and in the end of that year, or the beginning of 1563, Teresa took up her abode therein; and in 1565 she obtained from pope Pius IV. a formal approval for the rule as modified by her. For two years Teresa lived in great privacy and quiet in her convent of St. Joseph; but in 1567, the general of the Carmelite order, F. Rubeo, was so struck, during his visitation of the convents at Avila, with the condition of that over which Teresa presided, that he urged upon her the duty of extending throughout the order the reforms thus successfully initiated. Teresa entered upon the work with great energy, and although she met with much opposition, nevertheless succeeded in carrying out her reforms. In 1579, the Carmelites of the stricter observance established by Teresa were released from the jurisdiction of the old superiors, and united into a distinct association, with a separate head and a distinct organization, which was approved in 1580 by pope Gregory XIII. Under this new constitution, the association flourished and extended; and within the lifetime of Teresa, no fewer than 17 convents of women and 16 of men accepted the reforms which she had originated. Teresa died at Alba, October 4, 1582, in her 68th year. She was canonized by Gregory XV. in 1621, her feast being fixed on the 15th of October. She left a number of works, which have at all times maintained a high reputation among the spiritualists of her own church, and whose merits, in many respects, are acknowledged by non-Catholic writers. They consist of ascetical and mystical treatises, instructions in the conventual life, meditations, etc., besides a large number of letters, which possess remarkable literary merit, quite independent of their doctrinal character. Her works in the original Spanish fill two folio volumes, and they have been in the whole or in part translated into almost every European language. Her life occupies nearly an entire volume of the new continuation of the *Acta Sanctorum*; and several more popular biographies have been written in Spanish, French, Italian, German—the best-known English one being that by the rev. Canon Dalton. See *Leben der heil. Theresia* von Dr. Fr. Pözl (Regensburg, 1847).

TERHUNE, MARY VIRGINIA (HAWES), b. N. Y., 1825; married, 1856, the rev. Dr. Edward P. Terhune, now pastor of the First church (Congregational), Springfield, Mass.; contributed at the age of sixteen to *Godey's Lady's Book* a sketch entitled *Marrying from Prudential Motives*, which was copied into an English paper, thence transferred to a French journal, retranslated into English, and published in England and America as an English story. Her publications are: *Alone; The Hidden Path; Moss Side; Husbands and Homes; Miriam; Nemeses; Sunnybank; Husks; The Christmas Holly; Ruby's Husband; Phemie's Temptation; Helen Gardner; The Empty Heart; Common Sense in the Household*, a book of domestic recipes; *Loiterings in Pleasant Paths*.

TERLIZZI, a flourishing, well-built town of Italy, in the province of Bari, 20 m. s.e. of Barletta, and 8 m. from the Adriatic. It contains a cathedral, a parish church, and three convents. The almond tree is extensively cultivated in the vicinity. Pop. about 19,000.

TERM, in legal phrase, has several meanings, but that best known is when it denotes certain days of the year for calculating rent between landlord and tenant, and which have been adopted by immemorial usage, owing to the convenience of thus terminating the contract between the parties. In England and Ireland the year is for this purpose divided into four quarters or terms. These are—Lady-day, Mar. 25; Midsummer-day, June 24; Michaelmas-day, Sept. 25; and Christmas-day, Dec. 25. In Scotland, the terms as between landlord and tenant are divided into legal and conventional terms. There are two terms recognized by common law, viz., Whitsunday, May 15, and Martinmas, Nov. 11; while other two conventional terms subdivide these, viz.,

Candlemas, Feb. 2; and Lammas, Aug. 1.—There is also a subdivision of the year into law-terms (q.v.), adopted and sanctioned by statute for the purpose of the sittings of the law-courts. These are Hilary, Easter, Trinity, and Michaelmas terms.—There is a third and technical meaning of the word “term,” when it means an estate for years in land.

TERMINI (anc. *Therma Himærensens*), a sea-port town on the n. coast of Sicily, 21 m. e.s.e. of Palermo, at the mouth of the river Termini. It is built partly on a plateau (the summit of which is crowned by a castle—now a prison—of mediæval construction), and partly on the slope and in the hollow beneath. Termini, with its noble background of towering hills, and its magnificent view of the Mediterranean, well deserves the title of *La Splendidissima*, bestowed on it by the emperor Frederick II. Many of the inhabitants are engaged in fishing for tunny and anchovies. Pop. about 20,000.

The ancient *Therma* (of which Termini is an Italian corruption) was founded 408 B.C., after the destruction of the Greek city of Himæra, and whence its name Himærensens, whether it owed its origin to the Carthaginians themselves, or to the surviving citizens of Himæra, is doubtful; but it soon passed under the authority of the former, who here defeated the Romans with heavy loss (260 B.C.) during the first Punic war. After Sicily became a Roman province, *Therma* was treated with peculiar consideration by its new masters, and became a flourishing place. Relics of the ancient city, as the baths (which are still used), fragments of a theater and aqueduct, are still visible; and numerous inscriptions, statues, etc., are preserved in public and private collections.—See B. Romano's *Antichità Termitane* (Palermo, 1828).

TERMINUS, a Roman divinity, supposed to preside over public and private boundaries. Originally he appears to have been the same as Jupiter himself, but gradually he was recognized as a separate and distinct god. Hardly any religious conception is more thoroughly characteristic of the Romans, that land-loving, law-reverencing people, than the conception of Terminus, whose worship was practiced down to a late period.

TERMITE, or **WHITE ANT**, *Termites*, a genus of insects of the order *neuroptera*, and and of the family *termitidæ* or *termitinæ*. They live in great communities, chiefly in tropical countries, and are almost omnivorous, in the larva- and pupa, as well as in the perfect state. In their communities there are five classes—males, females, workers, neuters, and soldiers. The workers, neuters, and soldiers seem all to be imperfectly developed females. The males and perfect females have four wings, which are long and nearly equal, and which are often suddenly cast off before the termination of their life; but the greater part of the community consists of workers, which are wingless. The “soldiers” are larger than the neuters, and have very large mandibles, which they are always ready to use upon any assault. The antennæ of the genus *termes* are long and thread-shaped, with about 20 joints; the eyes are small and prominent, and there are three *ocelli*; the abdomen has a pair of minute caudal appendages. Most of the white ants make their nests on the ground, but some of them among branches of trees, decayed or dry wood forming a principal article of their food. The species which make their nests on the ground make them conical, or turret-shaped, often 12 ft. and sometimes even 30 ft. high, in groups, like a little village. The soil where the white ants have labored is particularly good, and the south Africans take advantage of its excellent quality. The nest is divided internally into numerous chambers and galleries; there are generally two or three roofs within the dome-shaped interior, and the thick walls are perforated by passages leading to the nurseries and magazines of food. If a breach is made in the building, the soldiers appear, ready for defense. White ants are very useful in consuming every kind of decaying animal or vegetable matter. They even eat grass, and the snapping of multitudinous mandibles has been likened to the sound of a gentle wind among trees. They sometimes attack the wood-work of houses, and soon reduce the thickest timbers to a mere shell. Extraordinary and incredible stories are told of their attacking and devouring large animals, but it seems probable that they do so only when the animals are helpless from age or sickness. They come in vast hosts to any place where food is to be found, and are not easily driven off; multitudes pressing on, although previous multitudes have been destroyed. They gather great stores of corn into their nests, of which the natives of Africa often avail themselves. They are themselves also used as food in Africa, and are said to be delicate and pleasant. The abdomen of the pregnant female termite becomes dilated to an extraordinary degree, so as to exceed the rest of her body 1500 or 2,000 times, and she is then about 1000 times heavier than the male insect. Her fecundity is prodigious; she is supposed to lay more than 31,000,000 of eggs in a year.

The termites which live in trees construct nests of great size, like sugar-casks, of particles of gnawed wood, cemented by a kind of gluten, and so strongly attached to the branches as not to be shaken down even by violent storms. These species sometimes take up their abode in the roofs of houses, where they are very destructive to the wood-work.

T. mordax and *T. atrox* are among the African ground-building species. *T. lucifugus* is found in the s. of Europe, and has proved very destructive in the navy-yard of Rochefort, and elsewhere in the s. of France. Sulphurous gases and chlorine are forced into its galleries, without effecting its extirpation. *T. flavicollis* is very injurious to olive trees in Spain. *T. frontalis* extends as far n. in the United States as Massachu-

setts, and does mischief in vineyards, not only attacking dead wood, but the roots of living vines. No true species of *ternes* is found in Britain, but some of the *terniidae* are British insects. One of them is *psorus pulsatorius*, one of the insects which emit a sound like the ticking of a watch in houses. The species of the genus *psorus* are very small, active insects, living beneath the bark of trees, in wood, straw, etc. Some of them are found among books and in collections of natural history.

In books of travels, the termites are often called ants, their habits being similar, although they belong to a different order of insects.

TERN (*Sterna*), a genus of birds of the gull family (*laridae*), by some made the type of a distinct family (*sternidae*); having the bill as long as the head, or longer, nearly straight, compressed, slender, tapering; the wings long and pointed; the tail long and forked. The plumage is very full. From their forked tail, manner of flight, and small size, the terns are often called sea-swallows. They are incessantly on the wing, skimming the surface of the water, and catching small fishes and other small animals from it. The species are numerous, and are found in almost all parts of the world. Some of them are of very wide geographic distribution. Many are birds of passage. Thus, all which occur on the British coasts, and in other northern parts of the world, are mere summer visitors. The COMMON TERN (*S. hirundo*) is abundant on the more southern shores of Britain, but rarer in the north. It is found also on the coasts of Europe, Asia, and Africa, from the Arctic circle to the furthest s.; but there is some doubt if its range extends to America, where a very similar species, Wilson's T. (*S. Wilsoni*), was long mistaken for it.

TERNANT, JEAN DE, Chevalier, 1740-1816, b. France; was with the French army in America during the revolutionary war. Baron Steuben made him one of his inspectors in 1778. He was afterward lieutenant-col. and inspector of troops in the south, was captured at the surrender of Charleston in 1780. After his exchange he returned to his former position in the south. He was a col. in the French army during the French revolution, and minister to the United States, 1790-93.

TERNATE. See MOLUCCAS.

TERNAUX, GUILLAUME LOUIS, Baron, 1763-1833, b. Sedan, France. When but a boy he became manager of his father's woolen mill, and by his business sagacity rescued its finances from ruin. He was a deputy to the assembly, 1818-23 and 1827-30. The revolution of 1830 was brought about by the position taken by Ternaux and his party, and by it he lost a large fortune. He introduced improvements in manufactures and wrote several treatises on financial and industrial subjects. His nephew, HENRI TERNAUX-COMPANS, 1810-64, was noted as a collector of old books, his library of works bearing on the discovery and conquest of America being the finest in existence. He published a *Bibliothèque Américaine*, 1493-1700 (1837).

TERNAY, CHARLES LOUIS D'ARSAC DE, 1722-80, b. France; entered the French navy in 1738. In 1762 in command of a squadron he attacked Newfoundland, and captured St. John's, and several British vessels. He was governor of the island of Bourbon, 1772-79. The next year he commanded the French fleet bringing over to America count Rochambeau and his forces. He died at Newport soon after his arrival.

TERNI (anc. *Interamna*) a t. of central Italy, on the right bank of the Nera (anc. *Nar*), a little below its confluence with the Velino, 49 m. n.n.e. of Rome. It is encircled by a wall, with towers and five gates, is well-built, gives name to an archbishopric, and possesses a cathedral, several fine palaces and churches, a hospital, theater, and various monuments of antiquity, as the ruins of an amphitheater, temples, and baths—none of which, however, are of much importance. Terni manufactures silk and woolen fabrics. Pop. about 14,000. About 2 m. from the town is the famous cataract of Velino, 500 ft. high, celebrated by Byron in his *Childe Harold*.

Ancient *Interamna*, according to classic tradition, was founded only 80 years after Rome, but we have no knowledge of its history until it ceased to be an Umbrian, and became a Roman city. About the time of Marius and Sulla, it was (according to Florus) one of the *florētissima Italiæ municipia*, but at no period did it occupy a very prominent position. Its chief claim to notice arises from its being regarded (by some) as the birthplace of the historian Tacitus, and of his descendant, the emperor of the same name.

TERNSTROEMIA'CEÆ, a natural order of exogenous plants, allied to *guttifera*, and consisting of trees and shrubs, natives of warm and temperate countries. About 150 species are known. They are most abundant in South America; a few are found in North America; some in India, China, and other parts of the east; only one African species is known; and Europe produces none. The leaves are alternate, leathery, in many species evergreen, generally undivided, sometimes dotted. The flowers are on axillary or terminal stalks, generally white, sometimes pink or red; with 5 to 7 concave, leathery, deciduous sepals, and 5 to 9 petals, which are often combined at the base; many hypogynous stamens, which are either free or variously combined; 2 to 7 filiform styles, more or less combined; the fruit a 2 to 7-celled capsule, either opening by valves, or leathery and indehiscent, the seeds large, few, and attached to the axis, the cotyledons very large, and often containing much oil. This order is very important as containing the tea-

shrubs. It is also interesting because of the great beauty both of the foliage and flowers of many of the species, of which the genus *camellia* affords the best-known examples. See TEA, CAMELLIA, and GORDONIA.

TERPAN'DER, a Greek musician who flourished in the beginning of the 7th c. B.C. He was born at Antissa in the island of Lesbos; went to Sparta, and in 676 was crowned victor in the first musical contest at the feast of Apollo Carneius. He established there the first musical school in Greece. He enlarged the compass of the lyre to an octave, and was the first who regularly set poetry to music.

TERPSICHORÉ (Gr. delighting in the dance), one of the nine muses (q.v.), presided over choral song and dancing.

TERRACINA (anc. *Tarracina*), a t. of central Italy, in what was formerly the Papal States, is situated on the coast at the s.e. extremity of the Pontine Marshes, near the mouths of the Ufente and Amaseno. It is the seat of a bishop, possesses a cathedral (built on the ruins of a heathen temple), a square with a handsome fountain, a palace of Pius VI., and on the summit of a precipice overlooking the town, the ruins of a palace of Theodoric, king of the Goths. The harbor, a naval station of the Romans, is now filled up. Pop. 7,600.

Tarracina was originally a Volscian town, and was called by the Volscians *Anxur*, a name which is often applied to it by the Latin poets. It fell into the hands of the Romans, 400 B.C., became the seat of a Roman colony, 329 B.C., and as long as therepublic and empire lasted was a flourishing and important city. So closely do the mountains here approach the sea that there was scarcely room for the celebrated "Appian way;" hence the importance of Tarracina as a military position. Numerous ruins of the ancient town are extant.

TERRA or TELUS, in classical mythology, one of the oldest of divinities, the earth-goddess, wife of Uranus, mother of Oceanus, the Cyclops, the Titans, the giants, Themis, Mnemosyne, etc. Her festival was on April 15, and sacrifices were offered to her in spring and autumn. She corresponds to the Greek Ge, called by Hesiod the first-born of Chaos.

TERRA COT'TA, an Italian term signifying *baked clay*. It is applied chiefly, if not altogether, to manufactures of brick-earth used for ornamental purposes, especially those used architecturally. Formerly it was not uncommon in Britain, particularly about the beginning of the 18th c.; but after the reign of queen Anne it was discontinued, and was scarcely ever used until within the last ten years. A complete revival has now taken place, and this material has been applied with admirable effect in some of the buildings lately erected, especially the South Kensington museum, and the Charing Cross railway station hotel.

TERRA DEL FUEGO (Land of Fire), an archipelago situated at the extreme s. of South America, from the main land of which it is separated by Magellan's strait, consists of 11 large islands, of which the chief is King Charles's South Land, and about 20 islets; lat. 52° to 56° s., long. 65° to 75° west. The area of King Charles's South Land, which forms more than three-fourths of the entire area, is about 21,260 sq. miles. This island, like the other islands of the archipelago and the coast of the main-land, is much broken on the west side by gulfs and inlets. The eastern coasts are, as a rule, level and wooded; while the western coasts are generally rocky and mountainous. The general aspect of the group is wild and desolate in the extreme. Some localities, however, are of quite a different character. The coast-scenery of Picton island resembles that of the s.w. coast of England. The s. part of the island is chiefly in moor and down; the n. part is covered with thick forests. The scenery is fine, and there are fine fresh-water lakes, frequented by abundance of water-fowl. Many of the mountains are volcanic—from which circumstance this region has derived its name—and lava and volcanic productions are seen everywhere. The highest mountains rise to from 6,000 to 7,000 feet, and are covered with snow. The climate is raw and cold, violent rains and snow-storms occurring in every season of the year. In this region the waters of the Atlantic and Pacific meet and struggle together, and terrific tempests are frequent. The flora of the region comprises some plants found in Great Britain. Wild celery and spoonwort are the only edible plants; but by far the most important articles of food are shell-fish, which abound on the coasts, and a globular fungus, which grows in clusters round the trunk of the antarctic beech—an elegant evergreen, and the prevailing tree in the archipelago. The inhabitants, the number of whom is estimated at 2,000, are generally described as a short, ugly, beardless race, with long black hair, of a rusty iron color, and occupying the lowest rank in the scale of civilization. Capt. W. Parker Snow, who visited Terra del Fuego in 1855, reports somewhat differently of the inhabitants. According to him the natives are robust-looking, powerful, and of the middle height, being on an average over 5 ft. 3 in. in height. The only quadruped among them is the dog. When driven to extremities they first eat their dogs, and then kill and eat the old women of their tribe. More than one attempt has been made to convert these savages to Christianity, but hitherto such attempts have proved abortive. In 1850 a mission-party of seven men, under capt. Allen Gardiner, the projector of the expedition, arrived at Terra del Fuego. The missionaries were not well received by the natives, and the narrative of their residence on these

coasts is simply a record of miserable disasters. Owing to the grossest mismanagement on the part of the home authorities, the wants of the mission-party were neglected, and they found themselves in a short time destitute of provisions. The relief that had been promised never came; and in the autumn of 1851 the whole party, after undergoing horrible sufferings, died of starvation. In the autumn of 1854 another missionary expedition set sail from Bristol for Terra del Fuego, under command of capt. W. Parker Snow; but after many endeavors the attempt to form a mission-station on Terra del Fuego was abandoned.

TER'RA DI LAVO'RO (*Campania Felix*), now CASERTA, a maritime province of s. Italy, bounded on the n.w. by what was formerly the Papal states. Area, 2,326 sq.m.; pop. '71, 697,403. This is the famous *Campania Felix* of the ancients. Pliny extols its beauty and its fine situation. Florus calls it the finest country in the world. In ancient times it was inhabited by the Ausonii, the Osci, and later by the Campani. The finest part of Campania has been separated from it, and is that fertile tract of country which surrounds the gulf of Naples like an amphitheater; another part has been added to the province of Molise. Terra di Lavoro is watered by two rivers, the Liris, or Garigliano, and the Volturno. Toward the e. it is broken up by the Apennines, and its beautiful ranges of hills are clothed with vine and olive yards, and studded with country-seats. It produces corn, strong wines, oil, fruits, and silk. Its sea-port towns are populous and busy, although here and there the sea-board is interrupted by marshes. The climate is very mild in winter, and extremely hot in summer.

TERRA DI SIENNA. See BURNT SIENNA.

TERRA FIRMA, a term frequently employed to denote continental land as distinguished from islands. But it was at one time more specially applied—1st, to all the main-land of Italy which acknowledged the supremacy of Venice—viz., to the duchy of Venice, Venetian Lombardy, the march of Treviso, the duchy of Friula and Istria; 2d, to that extensive tract of South America bounded by the Pacific ocean. Peru, the silvas of the Amazon, the Atlantic ocean, and the isthmus of Panama, which mostly belonged to the Spaniards during the last century. In a still more restricted sense, the term was applied by the Spaniards to the isthmus of Panama itself. Colloquially, the phrase *terra firma* is applied (but erroneously) to land as distinguished from water.

TERRA JAPONICA. See CATECHU.

TERRANO'VA, a sea-port town on the s. coast of Sicily, province of Caltanissetta, on the right bank of the Omonimo, 18 m. e. from Alicata. Pop. 14,974. There is no regular port, but the town carries on a good trade in fruit, corn, pulse, sulphur, soda, and, above all, in cotton, large quantities of which are grown in the vicinity. A kind of coarse cloth is manufactured for home consumption. Terranova is believed to occupy the site of the ancient Gela (q.v.). The town now standing was built by Frederick II. in the 12th century. In its neighborhood is the village of Mazarino, from which the famous cardinal took his name.

TERRAPIN, the popular name of many species of fresh-water tortoises, of the family *emydæ* (see EMTS), natives of tropical and the warmer temperate countries. The neck can be wholly retracted within the shell; the head is flat, and the jaws prolonged into a beak. They feed partly on vegetable food, but also devour fish, reptiles, and other aquatic animals. They swim very well, and even on land move with much greater swiftness than land-tortoises. Their flesh is generally much esteemed.—Several species are natives of North America.

TERRE BONNE, a parish in s.e. Louisiana; bounded on the s. by the gulf of Mexico, on the w. by Atchafalaya bayou, drained by Black, Caillon, Chene, and Terre Bonne bayous; traversed by the Louisiana and Texas railroad; about 1,800 sq.m.; pop. '80, 17,956—9,343 colored. The surface is level and heavily timbered. There are many small lakes. The soil is good. The principal productions are corn, molasses, and sugar. Co. seat, Houma.

TERREBONNE, a co. in s.w. Quebec, lying n.w. of the isle of Jesus, having the St. Lawrence river for its s. boundary; 545 sq.m.; pop. '71, 19,591. It is drained by the river Jesus, called the n. branch of the Ottawa. It has saw, grist, and woollen mills. Co. seat, St. Jerome.

TERRE HAUTE, a city of Indiana, U. S., on the e. bank of the river Wabash, 78 m. w.s.w. of Indianapolis; a handsome town, regularly built, on an elevated plateau, in a rich agricultural country, with three railways, the Wabash and Erie canal, machine-shops, and manufactories. It has 3 banks, 4 public school edifices, Roman Catholic convent and schools, free college, 13 churches, 3 daily and 3 weekly papers, 2 public libraries, and abundant supplies of bituminous coal. Pop. '70, 16,103.

TERRE HAUTE (*ante*), a city in s.w. Indiana; incorporated, 1853; co. seat of Vigo co., on fort Harrison Prairie; pop. '80, 16,103. It is the junction of the Terre Haute and Indianapolis railroad, the Evansville and Terre Haute, the Illinois Midland, the St. Louis, Vandalia, and Terre Haute, the Logansport and Terre Haute, the Chicago, Indianapolis, and St. Louis railroads, etc. The National road here crosses the river by a bridge. There are many elegant private residences; and the state normal school, the

Providence hospital and a polytechnic institute. It is lighted with gas and supplied with water. It has a market-house, city hall, a court-house, 6 weekly newspapers, 1 tri-weekly, and 3 dailies. The Wabash is navigable in the spring, and steamboats ply to points on the Ohio and Mississippi rivers. Its manufactures include blast furnaces, glass and iron works, machine shops, and nail factories.

TERRELL, a co. in s.w. Georgia, drained by the Flint river and its creeks; traversed by the South-western railroad; about 300 sq.m.; pop. '80, 10,451—10,435 of American birth; 6,184 colored. The surface is level and moderately fertile. Co. seat, Dawson.

TERRE-PLEIN, in fortification, is the flat surface of the rampart, on the front portion of which the parapet and banquette are formed, and of which the rear slopes down to the general level of the inclosure.

TERRESTRIAL MAGNETISM. In the article **MAGNETISM**, it is shown that the earth itself is to be considered as a great magnet; and in the present article it is proposed to exhibit the chief results of observation on the earth's magnetism as seen in its action on artificial magnets. That action is simply *directive*; that is, it determines the way in which the magnet shall point, but has no tendency to translate or move it bodily. Terrestrial magnetism acts differently at different places; what are called the *magnetic elements* of a place are the direction of the needle in regard to the points of the horizon (*variation* or *declination*), its direction in regard to the vertical (*inclination* or *dip*), and the *force* that keeps it in these positions (*intensity*). For the first two elements, see **DECLIN-**

FIG. 1.

ATION-NEEDLE and **DIPPING-NEEDLE**. The element of intensity is more difficult to determine. The relative horizontal intensity is measured by the number of oscillations that a needle, of unit size and strength, when disturbed makes in a given time, the intensities of two places being as the squares of the oscillations. The total intensity is got by dividing the horizontal intensity by the cosine of the angle of dip. Gauss has succeeded in reducing this measurement from a relative to an absolute standard.

Magnetic Charts.—The magnetic elements have been ascertained with great care at different portions of the earth's surface. The knowledge thus obtained has been embodied in magnetic charts, in which the points at which the declination is the same are joined by lines, and similarly those where the dip and intensity are alike. The lines of equal declination are called the *isogonic lines*; those of equal dip, *isoclinic*; and those of equal intensity, *isodynamic lines*. As the magnetism of the earth is subject to a slow secular variation, such charts are only true for the time of observation. The chart, fig. 1, was drawn up by col. Sabine for the year 1840, and gives an approximate view of the lines of equal declination for that year. The change since 1840 has been small, so that an isogonic chart for the present time would differ but slightly from it. The chart sufficiently explains itself. Attention may, however, be given to one or two points. The declination is marked on each line. Thus, the line passing through England, for instance, is marked 25°, and that passing n.w. of the British islands, 30°. At places under those lines the needle points to a n. 25° and 30° w. of the true north. On the space intervening

between these lines, including Scotland and Ireland, a correction, varying from 0° to 5° , must be made according as the station lies more toward the one line than the other. The westerly line of no declination passing northward cuts off the eastern corner of South America, proceeds to North America, which it enters at North Carolina, traverses the continent by lakes Erie and Huron and the w. of Hudson's bay, and ends in the n. of the continent at Boothia. The easterly line of no declination passing southward enters Europe in the n. of Russia, crosses the White sea to the e. of Russia, of the Caspian sea, of Persia, and the Arabian sea; then turns eastward, and cutting off the w. of Australia, passes southward. The space included between those two lines, and which in the chart is left untinted, constitutes, so to speak, the hemisphere of westerly declination. It includes the e. of the two Americas, the Atlantic ocean, the whole of Europe and Africa, and the w. of Asia and Australia. The rest of the earth, which in the chart is tinted, has an easterly declination. There is an elliptic space in Eastern Asia which is left white, having a westerly variation, and forms an exceptional region in the eastern magnetic hemisphere.

It will be seen that the lines converge in the n. of North America, and in the s. of Australia. So far as experience goes, and so far as the most matter-of-fact theory (Gauss's) teaches, the convergence in both cases is to a point. The point in North America is the *north magnetic pole*, and that s. of Australia is the *south magnetic pole*. At these points, then, all isogonic lines converge, and a compass-needle lies indifferently in any position.

These isogonic lines, as seen from the chart, form a somewhat complicated system. This arises from the fact that we refer the indications of the needle to the geographical poles, which are, so far as we know, arbitrary or extraneous as regards terrestrial magnetism. Duperrey, by drawing what he calls *magnetic meridians and parallels*, draws a system of lines which have much the same conformation with regard to the magnetic poles that the meridians and parallels of latitude have to the geographical poles. A magnetic meridian, according to Duperrey, is the line that would be described by a person setting out, say from the south magnetic pole, and traveling always in the direction of the magnetic n. till he reached the n. magnetic pole. The magnetic parallels are lines drawn at right angles to the magnetic meridians.

In an isoclinic chart by the same author and for the same epoch in the upper part of the chart, which is left white, the n. end of the needle dips; and in the lower part, which is tinted, the s. end of the needle dips. The amount of dip is marked on lines. Thus, the line passing through the center of England is marked 70° . A dipping-needle, at any place cut by the line, is inclined 70° to the horizon. The line 75° passes to the n. of the British isles. In Ireland and Scotland, therefore, the dipping needle has an inclination greater than 70° , and less than 75° . The line marked 0° is the line of no dip; at any station on it the dipping-needle is horizontal. This line is called the *magnetic equator*. It is not coincident with the geographical equator; it is not even a great circle of the earth, but is an irregular curve cutting the equator in two points, one near the w. coast of Africa, and the other in the middle of the Pacific ocean. The points on the earth's surface where the dipping-needle stands vertical, and where, in consequence, as before mentioned, the compass-needle lies in any direction, are called the magnetic poles. The n. magnetic pole was found in Boothia Felix by capt. Ross at $70^{\circ} 5' \text{ n. lat.}$ and $263^{\circ} 14' \text{ e. long.}$ According to Gauss's calculation, it should have been at the time (1831) some 3° n. of this point. From observations made at Hobart Town, the nearest station to it, the s. magnetic pole should lie $66^{\circ} \text{ s. lat.}$ and $146^{\circ} \text{ e. long.}$ These points are not diametrically opposite each other, as the geographical poles. If the lines of equal dip were drawn on a globe, they would form round the magnetic poles a system of irregular circles, somewhat resembling that of the parallels of latitude round the poles of the earth.

We do not add an isodynamic chart, as it would take up too much space. Col. Sabine's dynamical chart, along with the isogonic and isoclinic charts, will be found fully engraved and explained in Johnston's *Physical Atlas* (new edition). From this chart we learn that the magnetic intensity is least in the vicinity of the magnetic equator, and increases as we approach the magnetic poles. The lines of equal intensity, though running much in the same direction as the lines of equal dip, are neither coincident nor parallel with them. The line of least intensity, itself not an isodynamic line, runs nearly parallel to the magnetic equator, but lies, except in the western half of the Pacific, a few degrees to the s. of it. We thus learn that the changes in direction and intensity do not march together. We should fancy that at that point or points on the earth's surface where the dipping-needle stood erect we should be nearest to the center of free magnetic energy, and that there the force would be greatest; but this is not the case. The point in North America where the intensity is greatest is situated to the w. of Hudson's bay, some 18° s. of the n. magnetic pole. But this is not the only point of maximum force in the n. magnetic hemisphere. There is another, which was found by Hansteen in 1828, in Northern Siberia, about the longitude 120° . This maximum point is weaker than the American, in the proportion of 100 to 107 (Sabine). According to Gauss, there can only be one maximum point in the southern hemisphere which is stronger than either of the other two. It lies n.e. of the s. magnetic pole, and its intensity is 137 (Gauss) compared with 107, that of the principal northern center. At none of those

points does the dipping-needle stand erect. This want of coincidence of the points of vertical dip and of maximum intensity has led to some confusion in the use of the term magnetic pole; some writers meaning by it a point of vertical dip, and others a point of maximum intensity. In adopting the former definition we are only adhering to the popular meaning of the word, and to the opinion of Gauss, perhaps the greatest authority on the subject. Some of the best English authorities, however, attach to it the latter meaning.

Although the total intensity increases as we go northward or southward from the line of least intensity, the horizontal intensity diminishes. This arises from the fact that the greater the dip the less the horizontal intensity. Hence the compass-needle, which is affected alone by the horizontal intensity, oscillates more sluggishly as we leave the line of least intensity. A dipping needle, for instance, oscillates faster at London than at Calcutta, because the total intensity which affects it is greater at London than at Calcutta; but with a compass-needle it is the reverse, from the horizontal intensity being greater at the latter than at the former station.

Variations of the needle.—The magnetic elements do not remain constant in the same place, but are subject to continual though small variations. These are regular and irregular. Under regular variations are included *secular*, *annual*, and *diurnal* variations. The secular variations take centuries for their completion. The following list of the declination and dip at London in different years will give an idea of the secular variations for these elements:

Year.	Declination.	Year.	Inclination.
1576.....	11° 15' easterly.	1720.....	74° 42'.
1657-62.....	0° 0' no declination.	1780.....	72° 8'.
1760.....	19° 30' westerly.	1800.....	70° 35'.
1815.....	24° 27' 18" westerly.	1830.....	69° 38'.
	MAXIMUM.	1850.....	68° 48'.
1850.....	22° 29' 30" westerly.	1865.....	68° 9'.
1865.....	21° 6'	1875.....	67° 47'.
1875.....	19° 33'		

At present the annual decrease of declination at Kew is 8'. At this rate it would take rather more than 84 years for the compass-needle to shift through a whole point. From the observations of the dip we find that it has been gradually decreasing for the last 150 years. The annual decrease of dip is at present about 2.6'. The time during which observations have been taken of the declination and dip is far from comprehending a cycle of change in either, and it is a mere matter of speculation how long that may take. The magnetic history of London does not apply to other places, each place, so far as has been ascertained, having a magnetic history of its own. Thus, in Paris, the time of no declination was 1669; and of maximum declination, 1814; the latter amounting to 22° 34' west. Every place, according to Barlow, appears to have its own magnetic pole and equator. Magnetic intensity has been observed for so short a time that little as yet is known of its secular variation. At present the horizontal intensity is increasing in Europe, but that may arise partly from decrease of dip.

The magnetic elements are also subject to changes, which have a yearly and a daily period. In describing these shortly, we shall limit ourselves to the changes affecting declination, as these are of most general interest. The following are the chief particulars of the *annual variation* of declination given by Cassini: From April to July, or from the vernal equinox to the summer solstice, the western declination decreases. From the summer solstice to the vernal equinox, that is, during the other nine months of the year, the declination increases, the needle turning to the west. Its position in May and in October is nearly the same; so that in the winter months, from October to April, the westerly motion is slow. The range of the annual variation at Kew is 58' 55".

The mean *diurnal variation* for Kew is shown in fig. 2. The irregular line indicates the course of the n. end of the needle. A rise of this line indicates a change of the n. end to the e.; a fall, a change to the west. The interval between two horizontal lines corresponds to a deflection of the needle 1' to the e., and a fall 1' to the west. The line marked *o* is the magnetic meridian, or the mean daily position of the needle. The interval between two upright lines corresponds to an hour. The course begins at twelve at night, and ends at twelve the following night. At twelve at night, the magnet is 1½' e. of the mean position, and continues nearly in the same position, with only a slight westerly deviation, till 15 hours (three in the morning), when it veers eastward. At 20 hours (eight in the morning), it reaches its furthest e. point. From eight in the morning till one in the afternoon, it makes a sweep of 10' toward the w., and then stands about 6' to the w. of the mean. After one, it goes westward till midnight, when it again begins the same course. The needle stands in its mean position a little after ten in the morning, and a little before seven in the evening. The course here described is the course for the year. But the diurnal range is different in different months. In May, for instance, the average range between the extreme points is 12', which is the maximum range for the year; and in December, when it is a minimum, it is only 5' 28". The diurnal changes here described for Kew are much the same all over the n. magnetic hemisphere. The amount, however, is different. Near the magnetic equator the diurnal variation is little

or nothing, and it increases as we go northward. Captain Duperrey states that at or near the magnetic equator, the n. point of the needle in the morning shifts slightly e. or w. of the mean, according as the sun passes s. or n. of the station. In the southern magnetic hemisphere, the daily motions of the needle takes place much in the same way as in the northern hemisphere, only the s. pole take the place of the n. pole, and the direction of the deflections is reversed. The correspondence, and at the same time opposition, of the southern hemisphere is also shown from the time of maximum and minimum range. When the sun is in the northern signs of the zodiac, the range is a maximum in the northern, and a minimum in the southern hemisphere; and when the sun is in the southern signs, the reverse takes place. The diurnal variation is so small, that the ordinary compass-needle is not delicate enough to show it.

The *irregular variations* are those which break in upon the regular march of the diurnal variation, without in the main altering it. Instead, for instance, of the needle steadily going westward from 8 A.M. to 1 P.M., as shown in fig. 2, it makes, when affected by irregular variation, deflections eastward as well as westward, although it in

FIG. 2.

the main moves westward; so that the line between these hours, instead of being comparatively straight, would be an irregular zigzag. These disturbances of the mean course are sometimes considerable, amounting even to one or two degrees in extreme cases. On some days, the mean diurnal course is much disturbed, on others, very little; but it is never quite free from them. It has been found that places of the same longitude have similar disturbances at the same time; that those on opposite sides of the globe, or differing by 180° of longitude, have disturbances equal in amount, but opposite in direction; and that those situated 90° w. or e. of the disturbed regions, have little or no disturbance. The appearance of auroras is invariably accompanied by magnetic irregularities, and their effect extends far beyond the regions where they are visible. Earthquakes and volcanic eruptions have also a marked effect in this way. Humboldt gave the name of *magnetic storms* to these irregular disturbances. The frequency of these storms, and the amount of the diurnal variation, are found to be the greatest when sun-spots are most numerous. See SUN.

1. *Theories of Terrestrial Magnetism.*—The earliest theory was that suggested by Gilbert, in which it is supposed that a magnet in the middle of the earth extends from one magnetic pole to the other. On this supposition, the general phenomena of terrestrial magnetism may be accounted for—a needle, both by declination and dip, must point to the poles. This must always remain, from its simplicity, the popular theory on the subject. In consistency with his theory, Gilbert considered the n. pole of the magnet to be a s. pole, as he took the n. pole of the earth for his standard n. pole. If this theory were correct, the magnetic equator would be a great circle of the earth, and the magnetic poles would be 90° from it, which is far from the case. It is only a rough approximation to a just theory.

Halley endeavored to supplement Gilbert's theory by supposing two magnets of unequal strength crossing each other at the earth's center to be the cause of terrestrial magnetism. The theory of the two magnets or four poles was ably defended by Hansteen.

Barlow considered that the earth acted on the needle as if currents of electricity traversed it from e. to west. He imitated its action by wrapping a wire in parallel coils round a wooden globe, and causing a galvanic current to pass through it. Each turn of the wire represented a magnetic parallel, and the two ends of the coil the magnetic poles; and, to complete the analogy, the globe was movable on an axis, which stood in the same relation to the ends of the coil as the astronomical to the magnetic poles of the earth. When a small needle was placed on the globe, its declination and dip bore a striking resemblance to those of a needle similarly situated on the earth's surface. The objection to this theory is the difficulty of accounting for the origin of such currents in

the earth. To meet this, some suppose the earth to be a huge thermo-electric pile; as the heat of the sun falls on one side of it, currents are there generated which travel round the globe. But how, again, it may be asked, are the conditions of thermo-electricity implemented by the materials of the earth? This question still remains to be answered. The close connection between temperature and magnetism is shown by the diurnal variation of declination, the epochs of which closely correspond with those of the daily temperature, and by the fact that the isodynamic and isothermal lines manifest a marked correspondence. Sir David Brewster has also shown that there are two centers of maximum cold in the northern hemisphere, which are situated near to the two intensity poles.

Gauss did not start from any simple supposition of one or two magnets giving rise to the magnetism of the earth, nor did he assert or deny its electric origin. Considering the whole earth as magnetic, he aimed at determining how it must act as a whole at the different points on its surface. In order to make the equations he obtained theoretically in this attempt express the distribution on the earth, the magnetic elements of eight stations at a sufficient distance from each other on the earth's surface had to be ascertained and substituted in these equations. This done from the longitude and latitude of any station he considered himself prepared to deduce its magnetic elements. The magnetic charts which he sketched, though founded on the imperfect observations to which he had access, are singularly in keeping with fact, and go far to establish the correctness of his reasonings.

The secular variations are as yet wholly unaccounted for. The cause of the diurnal variation is universally attributed to the sun. Secchi, who carefully studied the diurnal variation of the needle, considers that the sun, so far as they are concerned, acts upon the earth as a powerful magnet at a distance.

Historical Sketch.—The discovery of the change in declination at different places is generally attributed to Columbus, and was one of the many important observations of his memorable voyage across the Atlantic. Robert Norman, an instrument maker in London, first discovered the dip of the needle in 1576. He was led to it by finding that needles nicely balanced before magnetization had to be slightly loaded on the s. end, to keep them horizontal after being magnetized. Gilbert (1600) gave the first theory of terrestrial magnetism, viz., that of the single magnet. Halley, the astronomer royal, published his theory of the four poles in 1683. In 1688 and 1689, at the expense of government, he made two magnetic voyages, the results of which he embodied in his charts of the lines of equal declination, published in 1701, which were the first magnetic charts ever published. In 1722, the diurnal variation was discovered by Graham, the celebrated instrument-maker of London. The first inclination chart was published by Wilke at Stockholm, 1768. Humboldt inaugurated the present system of careful observations of terrestrial magnetism by taking comparative measurements of the magnetic elements at Peru and Paris (1799-1803). Hansteen's work on the *Magnetism of the Earth* was published at Christiania, 1817; in 1826 he published the first isodynamic charts. Barlow (1831) suggested the electric origin of terrestrial magnetism. In 1831, captain Ross came upon the n. magnetic pole. In 1835, stations were established throughout Europe, and the observations were published by Gauss and Weber, 1836. Gauss (1823-1840) perfected his theory. In 1837, col. Sabine published an isodynamic chart of the whole globe. Observations were made (1840-1854) at stations throughout the British empire by British officers, under the direction of col. Sabine.

TERRESTRIAL TEMPERATURE. The distribution of heat over the globe is represented by isothermal lines, or lines drawn through all places having the same mean temperature.

The part of the globe having the highest mean annual temperature forms an irregularly shaped belt, lying along the equator, and comprised between the n. and the s. isothermals of 80° . On either side of this warm belt the temperature diminishes towards the poles; and the lines in a chart showing successively this diminution are, speaking in a very loose sense, arranged parallel to the equator, thus showing the all-predominating influence of the sun as the source of terrestrial heat. The coldest portion of the earth's surface is a small oval-shaped patch near to but not surrounding the n. pole, its mean temperature being -4° . Its narrowest diameter lies n. and s. nearly touching the pole on the one side, and extending on the other as far s. as $72^{\circ} 30'$ n. lat. in 130° w. long. On looking at a chart representing the isothermal of 0° , one might be led to suppose that there are two centers of greatest cold, one n. of Siberia, and the other n. of British America. Such, however, is not the case—the apparent double center of greatest cold being solely due to the isothermals being drawn on Mercator's projection of the earth; for if an isothermal map be drawn on a polar projection, the lines of mean annual temperature inclose one connected space of greatest cold, and not two such spaces, as is not unfrequently stated.

While the decrease of temperature in advancing toward the poles corresponds in a general way to what may be called the solar climate, there are deviations brought about by disturbing causes too important to be overlooked. These disturbing causes are (1) the currents of the sea; (2) the prevailing winds; and (3) large surfaces of water which are frozen during part of the year.

The influence of an oceanic current depends on the temperature of the place it leaves and the place at which it arrives. Hence the great equatorial current, flowing from east to w. does not require to be considered here, because the heat remains the same throughout its course; but only those currents which convey the waters of the sea to higher or to lower latitudes. Of these, the most marked and important is the Gulf stream in the North Atlantic, which, by conveying warm water to the arctic regions, pushes the isothermals many degrees to the northward. There is a similar, though much feebler, current passing from the North Pacific to the Arctic Sea through Behring's strait, and there, accordingly, the isothermals are pushed a little to the northward. In the southern hemisphere, there are two currents, one discovered by Humboldt, passing from the Antarctic Ocean northward by the coast of Peru as far as Lima; the other flowing from the cape of Good Hope northward along the w. coast of Africa: these currents, flowing from colder to warmer latitudes, lower the temperature, and thus drive the isothermals toward the equator. Again, the great equatorial current, after impinging on the e. coast of Africa, turns southward, and by the warmth it imparts, pushes the isothermals into higher latitudes. For the same reason the current flowing southward past the coast of Brazil, raises the temperature in the e. of that country. The influence of these great currents is more distinctly marked in the forms of the isothermals for January and July. Thus, in January, when the relative excess of the temperature of the Gulf stream is greatest, the isothermals are driven very far to the north; and similarly in the southern hemisphere, the currents from the Antarctic Ocean being coldest in July, the isothermals are deflected more toward the equator during that month. The most remarkable lowering of the isothermals occurs in Labrador and Newfoundland during May and June, and is caused by the icebergs which then descend on these coasts from Davis's strait.

Since winds bring with them the temperature of the regions they have crossed, the equatorial current is a warm wind, and the polar a cold wind; also winds arriving from the ocean are not subject to such variation of temperature during the year as winds from a continent. As an atmosphere loaded with vapor obstructs both solar and nocturnal radiation, it follows that moist winds are accompanied with a warm temperature in winter, and a cool temperature in summer; and dry winds with cold winters and hot summers. The direction of mountain-ranges is also an important element to be taken into account in estimating the influence of winds on temperature. These considerations explain the position of the isothermals in the north temperate zone, where the prevailing wind is the s.w. or anti-trade (see WINDS). In January, the western parts of each continent enjoy a comparatively high temperature, from their proximity to the ocean, whose high temperature the winds waft thither; and they are further protected from extreme cold by their moist atmosphere and clouded skies. But in the interior of the continents it is otherwise; for the winds getting colder as they advance, and being deprived of their moisture as they cross the mountains in the w., the soil is exposed to the full effects of radiation during the long winter nights, and as a consequence, the temperature rapidly falls. In the center of Siberia, the January temperature falls to -40° , which is 2° colder than the coldest part of the American continent; and this center of greatest cold lies near the eastern part of the continent of Asia. On the other hand, in July, the interior of continents is much warmer than their western parts. Hence the interior and eastern parts of Asia and America are characterized by extreme climates, and the western parts by equable climates. Thus, at Yakutsk, in Siberia, the July temperature is $62^{\circ}.2$, and the January $-43^{\circ}.8$, the difference being $106^{\circ}.0$; while at Dublin these are respectively $60^{\circ}.8$ and $38^{\circ}.5$, the difference being only $22^{\circ}.3$. This constitutes the most important distinction of climates, both as respects vegetable and animal life. On man especially the effect is very great—the severity of the strain of extreme climates on his system being shown by the rapidly increasing death-rate as the difference between the July and January temperatures increases.

The great fresh-water lakes of North America—lakes Superior, Huron, Erie, Michigan, Ontario, Bear lake, etc.—exercise an important influence on the climate of the central parts of North America, for in winter, America, with its frozen lakes, is a truly unbroken continental mass, and its winter climate is therefore continental; whereas in summer its numerous large sheets of fresh water communicate to it many of the features of an insular summer climate.

The whole effect of the disturbing causes is seen at once, if we compare the observed temperature of a place with its normal temperature, that is, the temperature due to it in respect of its latitude. In the northern hemisphere, in January, the sea and the western parts of the continents are in excess of their normal temperature; elsewhere, there is a deficiency. There are two centers of excess, one to the n.e. of Iceland, amounting to 41° ; the other in Russian America, amounting to only 18° ; and two centers where the temperature is deficient, one at Irkutsk, amounting to 41° ; and the other w. of Hudson's bay, amounting to 27° . In July, the United States, Europe, Asia, the Indian ocean, the n. of Africa, and the extreme n. of South America, have their temperature in excess, while elsewhere it is deficient. The centers of excess are: n. of Siberia, $13^{\circ}.5$; Red sea, $11^{\circ}.0$; and n.w. of the United States, $4^{\circ}.5$; and the centers where the temperature is deficient are: the entrance to Hudson's bay, $11^{\circ}.0$; and the Aleutian islands, $11^{\circ}.0$.

TERRIER, a small kind of dog, remarkable for sagacity, vivacity, courage, and eagerness in the pursuit of "vermin," which it readily follows into burrows; whence apparently the name terrier, from Lat. *terra*, the earth. The courage of the terrier, however, is such that it will readily attack animals much larger than itself; and it has been observed in India that terriers will fearlessly rush at the largest carnivora, when even the bull-dog hesitates. Terriers are of great use for killing rats in places much infested by them. They are also used for compelling the fox to leave his retreat; and a large variety called the *scaufinder*—that is, boar-seeker—is employed in Germany to rouse the fiercest beasts of the forest from their lairs. The varieties of terrier are numerous. In Britain, two are particularly prevalent, known as Scotch and English terriers—the former with long, rough, wiry hair, with which even the face is much covered; the latter with smooth, short hair. The ears are either erect and pointed, or have pendent tips. The Skye terrier is a breed of Scotch terrier, peculiarly prized. If any kind of dog may be regarded as truly indigenous in Britain, it is the terrier; but there is no certainty that it was not imported by the first inhabitants. Dogs very similar have existed in the north of Europe in a domesticated state from remote antiquity. The **BULL TERRIER** is probably a cross between the terrier and the bull-dog (q. v.).

TERRITORIES, in the United States and under similar governments, are those portions of the public lands set off by congress and still under its direct authority, while having the capacity to become states whenever congress gives its consent. Each territory has a governor, a judiciary, and other administrative officers appointed by the president; and has a territorial legislature, the exercise of whose powers, limited in their degree, is subject to congressional revision. Usually, as soon as a territory has a population sufficient to entitle it to a representative in congress, it is empowered by act of congress to adopt a state constitution, whereupon it is admitted into the union. The present (1881) number of U. S. territories is 6.

TERRY, ALFRED HOWE, b. Conn., 1827; educated at the Yale law school. He was clerk of the Connecticut superior and supreme courts, 1854-60; col. of a Conn. regiment at the beginning of the war of the rebellion; and took part in the first battle of Bull Run. In command of another Conn. regiment he was at the capture of Port Royal. He took command of fort Pulaski after its capture; was made brig.gen. of volunteers in 1862, took part in the operations around Charleston, and at forts Sumter and Wagner. In 1864 he led a division of the army of the James, participated in the Virginia campaign, and was at Bermuda Hundred and the siege of Petersburg. He led a second expedition against fort Fisher in 1865, and took it by storm Jan. 15. He was soon made a brig.gen. in the regular army, and maj.gen. of volunteers for this victory. He assisted in the capture of Wilmington, and commanded the 10th corps during the North Carolina campaign. He has commanded a number of departments since the war.

TERSCHELLING, one of the chain of islands to the n. of Holland, lies in 53° 24' n. lat., the principal villages being Oosterschelling, Westerschelling, and Midland. It consists of fertile, arable, and meadow lands, is protected on the s. by large dykes, and in other parts by dunes, which are carefully preserved. Area about 45 sq. m.; Pop. 3,128. There is a good haven, a shipbuilding-yard, a woolen dyework, etc. The old church of the hamlet of Stroe (Stri) is supposed to be a former heathen temple. Terschelling was the birthplace of William Barentz, the celebrated Arctic explorer. See **NORTH-EAST PASSAGE**.

TERTIAN FEVER. See **AGUE**.

TERTIARY (Lat. *Tertiarius*, one of the third rank), a name given by church writers to a class in the Roman Catholic church, who, without entering into the seclusion of a monastery, aspire to practice in ordinary life all the substantial obligations of the scheme of virtue supposed to be laid down in the gospel. Whatever earlier traces of this institution may be observable, there is no dispute that it was under St. Francis and the mendicant orders generally that the institute of tertiary reached its full development. The rules of the institution of tertiary, such as they have since substantially been maintained, were made public in 1221. The associates must, of course, all be members of the church; and it is moreover required that all shall be of good repute and blameless life. The intending members must restore all ill-gotten goods, must renounce all evil practices, and abandon all feuds and enmities with their neighbors. Wives cannot be received without the consent of their husbands. The obligation of tertiary once accepted, is irrevocable, unless the party should be released, or should enter into a more strict religious order. The members are required to renounce luxury of life, profane exercises and amusements, costly or unseemly dress, and the use of arms, except in the necessity of self-defence. They must frequent the sacraments; hear mass, if possible, daily; observe the fasts of the church, as well as certain special austerities; avoid contention, litigation, and unnecessary oaths; cultivate charity toward all, with special obligations toward needy, sick, or afflicted brethren, and practice with more than common fervor the great Christian virtues. The tertiary are placed under the authority of superiors elected at intervals, and for a stated period, and are liable to an annual visitation, conducted by a priest appointed for the purpose. It is to be observed,

however, that none of these obligations were supposed to bind the members under pain of mortal sin.

Such was the celebrated institute of the tertiary, or the third order of St. Francis. Similar lay associations were organized in connection with the Dominican, Carmelite, and Augustinian, as well as with certain of the more modern orders; and a brotherhood of the same character had already been formed by the Templars. It ought to be added, that the tertiary institute, properly so called, is quite distinct from that of the lay "confraternities" which exist in connection with the several orders, and the objects of which are very similar.

TERTIARY, the term applied in the science of geology (q.v.) to all the strata of the earth's crust above the cretaceous rocks, with the exception of those superficial beds which have recently been raised to a distinct group, under the title of the quaternary system, or recent period. There is considerable difference of opinion as to the division-line between the two systems, some including the boulder clay and its associated beds in the one, and some in the other group. Tertiary is synonymous with *cainozoic*, and is divided into the *pleiocene* (q.v.), *miocene*, and *eocene* (q.v.) periods.

TERTULLIAN, a father of the church, and one of the earliest who used the Latin language in written compositions. In one passage, the genuineness of which there is no reason to doubt, he calls himself Septimius Tertullianus. The best manuscripts call him Quintus Septimius Florens Tertullianus. He was the son of a proconsular centurion—that is, a centurion who attended on the proconsul. He was born in Carthage. He was brought up a heathen, and from his own writings we learn that he was licentious in his conduct, and fond of the public shows. We know nothing more of his heathen life. Eusebius describes him as a man exceedingly well acquainted with the laws of the Romans, and his writings bear out the assertion. From this circumstance, some have identified him with a Tertullianus whose name occurs in the index of the *Pandects*, and have supposed that he acted as an advocate; but the supposition is a mere conjecture. We know nothing of his conversion. He became a presbyter in the church, but whether he held this office in Rome or in Carthage, is matter of dispute, and there are no data to determine the question. It is certain that he visited Rome, and was well acquainted with the affairs of the Roman church. He also married; and as his wife was a Christian, it is supposed that his marriage took place after his conversion. After remaining a presbyter until he had reached middle age, he became a Montanist. Jerome attributes his adoption of Montanism to the insulting treatment which he received at the hands of the Roman clergy. But this is not likely an entirely accurate account of the matter. Jerome himself had been ill treated by the Roman clergy, and was therefore inclined to blame them; and in the character and general tendency of Tertullian's opinions, we have ample explanation of his passing over to Montanism. See **MONTANUS**. He lived to a good old age, remaining a Montanist to the last. We have no clue to precise dates in the history of Tertullian. Jerome states that he flourished under Severus and Antoninus Caracalla. Allix places his birth at 145 or 150 A.D., and his death at about 220 A.D.; but these are conjectures.

Tertullian was a man of strong and violent passions: he loved and hated with intensity. He possessed considerable culture, and was well versed in Roman law, in ancient philosophy, history, and poetry. He was not deficient in philosophical power, but he was narrow, bigoted, and uncharitable. He shows no sympathy with Greek speculation or with freedom of human thought; and he shows little sympathy with the joys and pleasures of man, being strongly inclined to asceticism. We need not wonder, therefore, that he came to believe in the paraclete of Montanus as the revealer of the perfection of Christianity, and that he adopted the Montanist opinions, that second marriages were adulteries, and that it was unlawful to flee in times of persecution, and wrong to receive the lapsed back into the communion of the church.

His writings are numerous. Attempts have been made to divide them into those which were written before he became a Montanist, and those written after that event; but the attempts have failed; for in treating many subjects he would have no occasion to say a word in regard to the paraclete, second marriages, or persecution.

His works are interesting, throwing much light on the internal circumstances of the church, on the social questions which perplexed Christians, on the opinions of heretics, and on the development of doctrine. Of his theology, Neander remarks: "In Tertullian we find the first germ of that spirit which afterward appeared with more refinement and purity in Augustine, as from Augustine the scholastic theology proceeded, and in him also the reformation found its point of connection." Among the peculiar opinions which he held may be mentioned his belief in the corporeality of the human soul.

His writings had great influence on the subsequent ages, but especially on Cyprian. Jerome says: "I saw at Concordia, in Italy, an old man named Paulus. He said that, when young, he had met at Rome with an aged amanuensis of the blessed Cyprian, who told him that Cyprian never passed a day without reading some portion of Tertullian's works; and used frequently to say: *Give me my master*, meaning Tertullian."

There are many editions of Tertullian; the best is by Franciscus Oehler (3 vols. 8vo. Lps. 1853). The third volume contains the principal dissertations on the life and writ-

ings of Tertullian. The works of Tertullian, with many dissertations and notes, form the first and second volumes of Migne's *Patrologia Latina*. The English reader will find a full and satisfactory account of Tertullian's life, writings, and opinions in bishop Kaye's *Ecclesiastical History of the Second and Third Centuries, Illustrated from the Writings of Tertullian* (8vo, 2d ed. Cambridge, 1829); and in Neander's *Anti-agnosticus or the Spirit of Tertullian*, translated by J. E. Ryland. A good translation of Tertullian's works will be found in Clark's *Anti-Nicene Christian Library*, edited by Drs. Roberts and Donaldson.

TERUEL, a province in n.e. Spain, adjoining Tarragona, Valencia, Saragossa, Castellon, Cuenca, and Guadalcajara, and forming part of Aragon; drained by the Tagus, Guadalupe, Guadalquivir and smaller streams; 5,494 sq. m.; pop. '70, 252,201. The surface is mountainous in part, being traversed by the Albarracin range from e. to w.; but there are large and richly productive plains, from which large quantities of wine, oil, fruit, hemp, and flax, are exported. The making of raw silk is an important industry. There are manufactures of linen and woolen goods and other articles. Capital, Teruel.

TESCHEN, a t. of Austrian Silesia, on the right bank of the Olsa, 38 m. e.s.e of Troppan. Pop. '69, 9,779. Here, in 1779, a treaty of peace was concluded between Maria-Theresa and Frederick II., by which the dispute of the Bavarian succession was brought to an end.

TESSERÆ, the small square tiles or cut stones used in forming tessellated pavements.

TEST ACTS, otherwise called *corporation acts*, the popular name given to two English statutes imposing certain oaths on the holders of public offices. Act 13 Car. II. c. 2, directs that all magistrates shall take the oath of allegiance and supremacy, as well as an oath renouncing the doctrine that it is lawful to take arms against the king, and provides that they must receive the communion according to the rites of the church of England within a year before their election. Act 25 Car. II. c. 1, imposed the like conditions on the holders of all public offices, civil and military, and obliged them in addition to abjure all belief in the doctrine of transubstantiation. These acts, which were practically evaded to a large extent by means of an act of indemnity passed every year, were repealed by 9 Geo. IV. c. 17, in so far as regarded the administration of the sacrament, for which a declaration set forth in that act was substituted. A statute of William IV. substituted a declaration for an oath in most government offices. A new form of oath has been substituted for the oaths of supremacy, allegiance, and abjuration by 21 and 22 Vict. c. 48.

TESTAMENT. See **BIBLE**.

TESTAMENT. See **WILL**.

TESTA TUM is one of the clauses of an English deed, otherwise called the witnessing or operative part, commencing at the words, "Now this indenture witnesseth that," etc.; and it includes a statement of the consideration-money, and the receipt thereof.

TESTER, or **TESTOON**, a flat canopy over a tomb, pulpit, etc.

TESTICLES. See **REPRODUCTION**.

TESTIMONIUM, in an English deed, otherwise called the attestation clause, is that part which states that the party signed the deed, beginning with the words, "In witness whereof."

TESTING, in chemistry, embraces a series of processes, the details of which would occupy far more space than the general plan of this work would admit of. Indeed, testing may be regarded as equivalent to qualitative analysis. As a simple illustration of the process of testing, we will assume that the most common of all chemical compounds, a salt, is submitted for examination. The student must pursue some such course as the following: 1. He must examine the dry substance before the blow-pipe, and note whether (a) it is volatile, as are the salts of ammonia and mercury; or (b) fusible, as are the salts of potash and soda; or (c) infusible, as are the salts of zinc, alumina, magnesia, lime, strontia, and baryta; or (d) reducible, as are the salts of silver, tin, lead, bismuth, antimony, and cadmium; and (e) whether it gives a coloration to the borax bead, and what that color is. 2. Having made his blow-pipe examination, he must bring his substance to a finely-divided state, and dissolve it, if possible, in water, and if it is insoluble in that fluid, even with the aid of heat, in hydrochloric or nitric acid. The solution, whether in water or acid, to which no test or reagent has been applied, is termed by Odling (*A Course of Practical Chemistry*, 2d ed. 1865) and others the *original solution*; and to this are added various tests, such as sulphureted hydrogen, hydrosulphate of ammonia, ammonia, nitrate of silver, etc. The most common effect resulting from the addition of a gaseous or liquid reagent is to cause a *precipitate* or solid deposit of either the base or acid sought for. These precipitates differ in their color, consistency, etc.; and the student must note not only the color of the precipitate (although this is the most important point), but also whether the deposit is crystalline, gelatinous, clotty, etc. 3. He must then ascertain to which group the base he is seeking for belongs. There are three great groups of bases; the members of the first group being precipitated from their acid or acidified solutions by sulphureted hydrogen (hydrosulphuric acid); those of the second

group not being thrown down by this reagent, but being precipitated from neutral solutions by hydrosulphate of ammonia (sulphide of ammonium); while those of the third group are not thrown down by either of these reagents. The first group includes tin, arsenic, antimony, bismuth, mercury, lead, silver, copper, and cadmium; the second, nickel, cobalt, manganese, iron, chromium, aluminium, and zinc; and the third, barium, strontium, calcium, magnesium, potassium, sodium, and ammonia. (See Odling, *op. cit.* p. 64). 4. Having ascertained to which base the group belongs, the next point is to identify it. For information on this point the reader is referred to any of the standard works on qualitative analysis, or on practical chemistry. 5. The base being thus determined, it remains to determine the acid, and in searching for it the student will be much assisted by a knowledge of the solubility of the most important classes of salts. Knowing, for example, the insolubility of the sulphates of baryta and strontia, he need not search for sulphuric acid in a soluble salt of one of these earths. On the other hand, a salt insoluble in water is not likely to be a nitrate or chlorate, or acetate or chloride (the only chlorides insoluble in water being chloride of silver and calomel). We cannot enter into the testing for acids further than to observe that the nitrates and chlorates deliquesce; the tartrates and citrates char; the carbonates effervesce when acted on by an acid more energetic than carbonic acid; the silicates, borates, and benzoates are precipitated by hydrochloric acid; and the arseniates and chromates react with hydrosulphuric acid. The presence of any particular acid is more or less indicated by its behavior, while still in union with the base, with strong sulphuric acid, which in many cases causes the evolution of characteristic fumes or vapors; and among the tests especially applicable for the detection of the acids (in acid solutions) are solutions of nitrate of baryta, nitrate of silver, chloride of calcium, and perchloride of iron. As the above remarks apply merely to the detection of the base and acid contained in a single salt, it will readily be understood how much the difficulties are increased when there is a mixture of several salts, or where, in place of a metallic oxide, a vegetable base is present, or where we have to deal with a complicated mixture of organic and inorganic substances, as, for example, in the investigation of the contents of the stomach in a case of suspected poisoning.—The following works on the subject may be referred to: Fresenius's *Qualitative Analysis*; Nood's *Qualitative Analysis*; Greville Williams's *Outlines of Chemical Manipulation*; Bowman's *Practical Chemistry*; and Odling's *Practical Chemistry*.

TESTING CLAUSE, in a Scotch deed, is the last clause, which narrates when and where the parties signed the deed, before what witnesses, the number of pages of which the deed consists, and who was the person who penned the deed. Moreover, if there have been any interlineations or erasures of important words during the engrossing, these should be mentioned in this clause. The clause is an essential part of a Scotch deed, and no deed which is written by another than the party is valid unless the testing clause is regular. The usual form is this: "In witness whereof, these presents, written on this and the five preceding pages by John Smith, residing at, etc., were subscribed by the parties as follows—viz., by the said A. B. at Glasgow on the 26th day of June, 1874, before these witnesses, W. X. of, etc., and Y. Z. of, etc."—In English or Irish deeds there is no necessity to enumerate these particulars in the attestation clause.

TEST-PAPERS are made by dipping un-sized paper, into an alcoholic solution of a vegetable coloring matter which changes color when exposed to the action of an acid or alkaline solution. The paper, after being gently dried, is cut into slips of a suitable size. Hence, by dipping the appropriate test-papers into any solution, we can ascertain whether it is acid, alkaline, or neutral. Litmus and turmeric are most commonly used as the coloring matters; litmus for the detection of acids, and turmeric for that of alkalis.

TESTUDO. See TORTOISE.

TESTUDO, in ancient warfare, was a defensive arrangement of the shields, by means of which a body of men advancing against a wall for assault or mining sought to protect themselves from the darts and weapons of the defenders. The men standing in close order joined their shields above their heads, the edges overlapping, until the whole resembled the shell of a tortoise (*testudo*).—The name was also applied to a machine moving on wheels, and roofed over, under which soldiers worked in undermining or otherwise destroying the walls in a siege. See BATTERING-RAM.

TETANUS (derived from the Gr. *teinein*, to stretch), is one of the most formidable diseases of the nervous system, and is characterized by an involuntary, persistent, intense, and painful contraction or cramp (see SPASM) of more or less extensive groups of the voluntary muscles, nearly the whole of the body being sometimes affected. There is usually a certain degree of order in which the different sets of muscles are affected. The muscles of the neck, jaws, and throat are almost always the first to give evidence of the presence of the disease. "The patient," says Dr. Watson, who has written a most graphic description of this terrible malady, "feels a difficulty and uneasiness in bending or turning his head, and supposes that he has got what is called a stiff neck. He finds also that he is unable to open his mouth with the customary facility. At length the jaws close; sometimes gradually, but with great firmness; sometimes (it is said) suddenly and with a snap. In four cases, perhaps, out of five, the disease begins in this way with

trismus or *lock-jaw*; so that this last is the vulgar name for the complaint. Along with this symptom, or very soon after it, the muscles concerned in swallowing become affected; and in a short time there comes on, what is often the most distressing part of the disorder, an acute pain at the lower part of the sternum, piercing through to the back. This pain depends, it can scarcely be doubted, upon cramp of the diaphragm, and is subject to aggravation in paroxysms. The spasm extends to the muscles of the *trunk*; to the *large* muscles of the extremities; the muscles of the *face*; and last of all, in general to the muscles of the tongue, and of the hands and fingers, which often remain movable at the will of the patient, after all the other voluntary muscles of the body have become fixed."—*Lectures on the Principles and Practice of Physics*, 4th ed., vol. i. p. 568. The muscles that are affected remain permanently contracted till either recovery or death ensues, and some of them, as, for example, the muscles of the abdomen, are so rigid, as when struck by the fingers, to resemble a board, although a perfect remission of the spasm scarcely ever occurs, except sometimes during sleep. Exacerbations of the spasms, on the other hand, commonly occur every ten minutes or quarter of an hour, usually beginning by an increase of the pain at the sternum, and lasting for two or three minutes; and as the disease advances, these paroxysms become more frequent. The powerful muscles of the back generally overcome the muscles in the front of the body, and when this excess of morbid power in the back is marked, the result is that the patient during the paroxysms rests solely on his head and heels, while his body is raised in an arched form. Occasionally the muscular contraction predominates in the opposite direction, and brings the head and knees in contact; and still more rarely, the body is bent to one side.

During the exacerbations, the face of the patient often presents a positively frightful appearance. The tongue is apt to get bitten during the contractions, which are occasionally so violent as to break the teeth, rupture powerful muscles, and at least in one case, to fracture the thigh-bone. Death usually results from a mixture of causes, but mainly from apnea (breathlessness), due to the fixed condition of the respiratory muscles, associated with asthenia (loss of power), and flagging of the heart's action.

There are two principal causes of this disease, viz. (1) exposure to cold and damp, and (2) bodily injuries. When tetanus arises from the *first* of these causes, it is termed *idiopathic*; and when from the second, *traumatic*. Idiopathic tetanus is so rare, at all events in this country, that we may pass on at once to the consideration of the traumatic variety. The disease is liable to follow any kind of injury, from a trifling cut or scratch to a compound fracture or the most severe operation, and is much more common in tropical than in temperate climates. The following table, given by Mr. Poland in his article "Tetanus" in Holmes's *System of Surgery*, vol. i. p. 306, gives the relative proportions which the occurrence of tetanus bears to various classes of surgical lesions observed at Guy's hospital during seven years:

There were of—

Major and minor operations.....	1364	cases—tetanus occurred in	1
Wounds of all varieties.....	594	"	9
Injuries and contusions.....	856	"	1
Burns and scalds.....	458	"	3
Compound fractures.....	396	"	9
Total.....	3668		23

From the large experience thus afforded, it appears that tetanus is most frequently met with in the more severe varieties of injury and accident, such as compound fractures, burns, and injuries to the fingers and toes. It is still a disputed point, whether the seat of the injury forms any special connection with the disease. Hennen, one of our greatest authorities on military surgery, observed it oftener after wounds of the elbow and knee; others, again, more frequently from injuries of the thumb and great toe. There is certainly a popular belief that wounds of the ball of the thumb are especially likely to be followed by tetanus.

The interval between the reception of the injury and the first tetanic symptoms commonly varies from the 4th to the 14th day, and rarely exceeds 22 days, some time in the second week being the most common period. As a general rule, the more rapidly the disease comes on, the more fatal will be the result.

More *trismus* or lock-jaw may be induced by affections of the teeth, especially by deficient dentition of the wisdom-teeth; but this is a purely local affection, in which the muscular contraction, though persistent, is never increased by painful spasmodic paroxysms, and which usually disappears on the removal of the exciting cause; and the general knowledge of this fact may tend to remove unnecessary terrors. Hysteria sometimes mimics the phenomena of tetanus with marvelous fidelity; and hydrophobia and tetanus have been mistaken for one another, in consequence of the spasm of tetanus sometimes affecting the muscles of deglutition, and inducing a fear of swallowing. There is, however, seldom any serious difficulty in detecting the difference between tetanus and any other disease. But there is a form of poisoning which produces almost every symptom of tetanus, and which may be termed *artificial tetanus*. If strychnia or brucia, or their salts, or vegetable matter containing either or both of these alkaloids, as *nux vomica*,

St. Ignatius's beans, or the juice of the upas tiente, be administered, either by the stomach or by inoculation, into the system, it induces all the symptoms of intense tetanus, and there is no test by which to distinguish the results of the disease and of the poisoning, except that, according to Dr. Christison, the disease never proves so quickly fatal as the rapid cases of poisoning with strychnia. See *NUX VOMICA*. And those who wish to study more minutely the comparative symptoms of strychnia-poisoning and tetanus, may consult the authorized *Report of Palmer's Trial*.

In the way of treatment, almost every known medicine has been prescribed, and whatever plan be adopted, a vast majority of the cases terminate fatally. As is the case with certain fevers, so tetanus seems to have a definite course to run; and as Mr. Poland wisely suggests: "All we can do is to enable our patient to weather out the storm by giving him as much strength as possible, and not adding fuel to the fire by all sorts of applications and internal remedies, which have over and over again signally failed. If we can help our patient on one day after another, we gain much: constant watching and constant attention are required by night as well as by day; an unflinching perseverance on the part of the sufferer in carrying out these views; besides the avoidance of all causes of excitement, and more especially the cold air or winds; taking care to preserve a uniform temperature as much as possible." When, in consequence of the strong contraction of the muscles of the jaw, it is impossible to open the patient's mouth, food and physic should be introduced into the stomach by means of a flexible tube passed through one of the nostrils.

The peculiar form of tetanus that occurs in newly-born children differs in so many respects from the disease described in this article that we shall briefly notice it in a separate article under the title of *TRISMUS NASCENTIUM*.

TETANUS, or **LOCK-JAW**, occurs in most of the domesticated animals, but most frequently in horses and sheep. It is usually produced by cold and wet, by intestinal worms, obstinate constipation, or injuries. The symptoms usually come on gradually, involve tolerably equally most of the muscular structures, which become hard and rigid; the nose is protruded, the limbs move stiffly, the tail is upraised, the bowels are constipated. The patient must be kept perfectly quiet, and in an airy but tolerably warm place, and plentifully supplied with cold water, and with soft, sloppy, but tolerably nutritive food, which he will usually greedily suck in through his firmly-closed teeth. A full dose of purgative medicine must at once be given; extract of belladonna repeated twice or thrice daily is occasionally serviceable; any discoverable wound or injury should be fomented or poulticed; bleeding, sedatives, and all causes of irritation must be avoided. In adult animals most cases are fatal; but among young animals, especially when the attack results from exposure to cold, many recoveries occur.

TÊTE-DU-PONT. See *BRIDGE-HEAD*.

TETRAGONIA CÆÆ, a natural order of exogenous plants, formerly included in *mesembryaceæ* (q.v.), from which it differs chiefly in the want of petals. The species are herbaceous plants or small shrubs, with alternate, thick, succulent leaves. A few are found on the shores of the Mediterranean, and some in Asia and the South Sea Islands, but the order abounds chiefly in the s. of Africa. New Zealand spinach (q.v.) belongs to this order. Other species are also used like spinach, as *sesuvium portulacastrum* and *S. repens* in the West Indies. Species of *aiyoon* are among the plants burned for barilla in Spain and the Canary isles.

TETRAHEDRON (Gr. *tettares*, four, *hedra*, a side), one of the five regular geometric solids, is a solid bounded by four equilateral triangles. The best idea of it is gained by considering it as a triangular pyramid, whose three sides and base are equilateral (and therefore equal) triangles. It is a form assumed by some crystals, and in crystallography is considered as a secondary form of the octahedron (q.v.), produced by removing the alternate angles or edges of the latter.

TE TRAO AND TETRAONIDÆ. See *GROUSE*.

TETRAPOLITAN CONFESSION, the creed of a body of Lutherans who held the doctrine of Carlstadt and of Zwingli concerning the Lord's-supper. It was drawn up by Bucer, 1531, was defended by Capito, and presented at the diet of Augsburg. The four cities which gave it a name—Constance, Strasbourg, Memmingen, and Lindau—held to it for many years.

TET RARCH (Gr. *tetrarches*, Lat. *tetrarcha*, "governor of the fourth part," i.e., of a country), a title originally designating what is signified by its etymology, the governor of one of four divisions of a kingdom or country; but, in the usage of the later Roman empire, given undistinguishingly to all minor rulers, especially in the east, possessing sovereign rights within their territory, but dependent on the emperor, and in many cases removable at his pleasure. This was especially the case in Syria, where the princes of the family of Herod are called indiscriminately by this title (Luke iii. 1) and by that of king (Matt. xiv. 9). The tetrarch in this latter sense was in truth a sovereign, although a dependent sovereign; and there are instances in which it seems to have been applied to really independent sovereigns of small principalities.

TETTER, the popular name for skin diseases of the kind described under *PSORIASIS* and *HERPES*.

TETUAN, a sea-port t. and small province on the n. coast of Africa, 22 m. s. of Ceuta, and 40 m. s. of Gibraltar. Area, 914 sq. m.; pop. 17,600. It is surrounded by walls, flanked with towers, and is defended by a castle. Its harbor does not admit large vessels; but a brisk trade is carried on in wool, silk, girdles, leather, cotton, etc., and it exports provisions largely to Ceuta. Oranges are grown in great abundance in the vicinity, and are exported to Spain, Gibraltar, Oran, and recently to England. Tetuan was taken by the Spaniards under O'Donnell (q. v.), Feb., 1860, but was evacuated next year. In 1873, 211 vessels, of 2,716 tons burden, entered the port of Tetuan.

TETZEL, or **TEZEL** (properly *Diez* or *Diesel*), **JOHN**, well known in connection with the controversy regarding indulgences, out of which the first beginnings of the reformation took their rise, was b. at Leipsic between 1450 and 1460. His father was a goldsmith of that city. Tetzel, after completing the ordinary studies of the period in the university, entered the Dominican convent of St. Paul in 1489, and soon established a reputation as a popular and effective preacher. His personal character is a subject of much controversy. The questions as to the teaching of Tetzel are more important. His ability and success as a preacher led to his being intrusted with the charge of preaching an indulgence, first on behalf of the Teutonic knights, and afterward, in 1516, on the far more momentous occasion of the celebrated indulgence published in favor of contributors to the fund for building the church of St. Peter's at Rome. In the discharge of this commission it cannot be doubted that Tetzel went to extremes which it is impossible to justify; but the worst charges, and especially that of preaching the efficacy of indulgences without repentance, and of offering anticipatory pardons for future sin, are strongly denied by Roman Catholic writers as being contradicted not only by contemporary authorities, but also by the very instructions contained in his official commission. Much of the obloquy which he drew upon his cause was produced by the pomp and apparent luxury in which he traveled about upon his mission. It was in opposition to the preaching of Tetzel that Martin Luther published his celebrated theses, on Oct. 31, 1517. Tetzel replied first by publicly burning these obnoxious propositions; but he afterward published a series of counter-theses (which were burned in retaliation by the students of the university of Wittenberg); and in May, 1518, a detailed reply to Luther's celebrated sermon on indulgences. On the arrival of the papal delegate Miltitz, Tetzel addressed to him a letter in reply to the charges of his adversaries; but, notwithstanding this defense of his conduct, he was summoned to appear before Miltitz in Leipsic in the January of the following year, and underwent a severe rebuke for the excesses in language and the improprieties in proceeding which had brought so much scandal upon the church. Miltitz threatened him, moreover, with the severest animadversions on the part of the pope. He was required in consequence to withdraw to his convent at Leipsic, where he died in the August of the same year, 1519, according to some of the plague, but according to another account, of the chagrin and mortification resulting from the judgment of the papal representative.—See, on the one side, Hechlein, *Vita. Tetzelii*; Hofmann, *Lebensbeschreibung des Ablass-predigers Dr. Joh. Tetzel* (Leip. 1844); and on the other, Schrödl, in *Wetzer's Kirchen-Lexicon*, art. "Tetzel," x. 767.

TEUCER, the name of two kings in ancient legend. The first, living in the Troad, whose people were called after him, Teueri, was the son, according to the mythologists, of the river-god Scamander and Idaea. He married his daughter Batea to Pardamus of Samethrace, who was his successor, and the founder of Dardania. The second Teucer was the son of Telamon, king of Salamis, and Hesione, daughter of Laomedon. He came with the Greeks to the Trojan war, on his return from which his father would not allow him to land at Salamis because he had not avenged the death of his brother Ajax. Teucer sailed for Cyprus, where he founded another Salamis.

TEUTOBURGER WALD (Lat. *Teutobergensis Saltus*). See **HERMANN**.

TEUTONIC, a term applied to a group of nations as well as of languages, forming an important division or stem of the Aryan (q. v.) family. The Teutonic languages will be found enumerated and classified in the table at the end of the article **PHILOLOGY**. The Teutonic stock of nations, as they exist at the present day, is divided into two principal branches: (1) The Scandinavian, embracing Danes, Swedes, Norwegians, Icelanders; and (2) the Germanic, which includes, besides the German-speaking inhabitants of Germany proper (see **GERMANY**) and Switzerland (q. v.), also the population of the Netherlands (the Dutch), the Flemings of Belgium, and the descendants of the Anglo-Saxons in Great Britain, together with their offspring in North America, Australia, and other British colonies. It is necessary in this case, as in all similar cases, to guard against making language the sole test of race. In many parts of Germany where German now prevails, Slavic dialects were spoken down to recent times, and in some places are not yet quite extinct. And in Great Britain it is unreasonable to suppose that the Anglo-Saxon invaders exterminated the native Celtic population, or even drove more than a tithe of them into the Highlands. The mass undoubtedly remained as subject serfs, learned the language and customs of their masters, and gradually amalgamated with them; so that, in point of blood, the English are perhaps as much Celtic as Teutonic.

Of the various tribes and nations spoken of as inhabiting northern Europe in ancient times, it is often difficult to determine which were really of Germanic race, and which Celtic or Slavic; the classic writers, having no skill in detecting the affinities of lan-

guage, had only confused notions of ethnology. Of undoubted German nations who took part in the destruction of the Roman empire, the most prominent were the Goths (q.v.), Lombards (q.v.), Vandals (q.v.), and Franks (q.v.). The term Teutonic is derived from *Teutones*, the name of a nation or tribe first mentioned by Pytheas, who wrote about 320 B.C., as then inhabiting a part of the Cimbric Chersonesus, or Jutland. For the next 200 years there is no further mention of the Teutones, that is, not until 113 B.C., when they appear in history as ravaging Gaul, and in conjunction with the Cimbric and Ambrones, threatening the very existence of the Roman republic. The Cimbric having gone into Spain, the Teutones and Ambrones were at length defeated by C. Marius in a great battle at Aquæ Sextiæ, or Aix, in Gaul, 102 B.C. in which from 100,000 to 200,000 of the invading army were slain, and many thousands made prisoners. A similar victory was gained by Marius in the following year over the Cimbric in the plains of Lombardy. It is disputed among ethnologists and historians whether the Cimbric so defeated were of the Celtic or of the Germanic race, and doubts have even been thrown on the claim of the Teutones to be considered Germans, although the best German scholars hold the claim to be established. Be that as it may, Roman writers, after the time of Cæsar and Tacitus, began to use the adjective Teutonicus as equivalent to Germanicus; and this practice was adopted in the middle ages by Germans writing in Latin. The native term was *theodisk*, from Goth., *thiud*, people; and it is from this word, and not from Teutonic, that the modern *Deutsch* is derived. See GERMANY.

TEUTONIC KNIGHTS, one of the more celebrated of the military and religious orders to which the crusades gave birth. The sufferings of the Christian soldiers at the siege of Acre excited the sympathy of certain merchants of Bremen and Lübeck, who rendered such important services by the erection of hospitals and otherwise, that duke Frederick of Swabia, with the sanction of pope Clement III. and the emperor Henry VI., enrolled them in an order of knighthood, as the Teutonic knights of St. Mary of Jerusalem. Only Germans of noble birth were made admissible to the order, the original founders having probably been ennobled before being enrolled. The members were at first all laymen, but priests were soon admitted as chaplains; and there was also added about 1221 a class of half-brothers similar to the serving-brothers of the Templars and Hospitalers. The habit of the order was a white mantle with a black cross; and the knights took vows of poverty and chastity, which in later times were not very strictly interpreted. Their first seat was Acre. On the overthrow of the kingdom of Jerusalem, the grand master removed to Venice, and from thence in 1309 to Marienburg, on the banks of the Vistula. In 1237, this order became united with the Brethren of the Sword in Livonia. In the course of the 13th c., the Teutonic knights were, with the sanction of the pope, engaged in a bloody war to enforce Christianity on the heathen nations inhabiting the southern shores of the Baltic, which resulted in the acquisition by the order of Prussia, Livonia, Courland, and other adjoining territories. Warriors from all parts of Europe in that and the following century joined their standard, including Henry IV. of England, accompanied by 300 attendant knights and men-at-arms. The conquests of the order raised it to the rank of a sovereign power, with a territory extending from the Oder to the Baltic, and embracing a population of between two and three millions, the grand master having his seat at Marienburg in Prussia. The decline of the order began in the 15th c., and its fall was brought about partly by internal dissensions, and partly by the attacks of neighboring states. Sigismund of Poland wrested w. Prussia from the knights; and Albert of Brandenburg, who was chosen grand master in hopes of his aiding the order against Poland, ended an unsuccessful war with Sigismund by an arrangement, according to which the territories of the order in e. Prussia were formed into a duchy, to be held by Albert and his successors. Mergentheim in Swabia then became the seat of the grand master, who was recognized as a spiritual prince of the empire. At the peace of Presburg in 1805, the emperor of Austria obtained the rights and revenues of the grand master; but in 1809 the order was abolished by Napoleon, its lands passing to the sovereigns in whose dominions they lay. The Teutonic order, however, still continues to preserve a titular existence in Austria.

TEVFIK I. See KHEDIVE.

TWEEKSBURY, an ancient market-t. and parliamentary and municipal borough of Gloucestershire, in the vale of Evesham, on the Avon, and near its confluence with the Severn, 10 m. n.e. of Gloucester. The parish church, an ancient and noble edifice in Norman, is the most noteworthy architectural feature. Hosiery, shoes, nails, leather, and malt are manufactured, and there is an extensive carrying trade, of which Tewkesbury is the center, on the Avon and Severn; pop. 71,540. Tewkesbury, a very ancient town, appears to be of Saxon origin. Within half a mile of it was fought (May 14, 1471) the famous battle of Tewkesbury, in which the Yorkists under Edward IV. and Richard III. inflicted a signal defeat on the Lancastrians.

TEXAS, one of the south-western states of America, is bounded on the s.w. by Mexico, from which it is separated by the Rio Grande; and on the e. by Arkansas and Louisiana. Area (greater than any other state or territory but Alaska), 274,356 sq. miles. Pop. '60, 601,039; '70, 818,579. It is divided into 174 counties. Among the chief towns are Austin, the capital; Galveston, the principal seaport; San Antonio, Houston, Brownsville, and Jefferson. Nearly the whole gulf coast is lined with bays, generally

long and narrow, with shallow inlets—that of Galveston being 12 feet. The chief rivers are the Red river, which separates Texas from the Indian territory; the Sabine, Trinity, Colorado, and Rio Grande. These rivers, mostly navigable from 300 to 400 m., run s.e., nearly parallel to each other, and empty into the gulf of Mexico. The country on the coast of the gulf is level, with a gradual ascent, the middle region undulating with rolling prairies; the w. is a high table-land, and the salt plains and staked plains (*el llano estacado*) on the borders of Arizona, are deserts 3,000 to 4,000 ft. above the sea, without trees, and in the summer without grass. There are a few small mountains in the west—spurs of the Rocky mountains. The river-bottoms are well timbered. In eastern Texas, wooded lands, called cross-timbers, alternate with prairies, and the country has a park-like and delightful aspect. The coast-region is formed of alluvial beds of sand or gravel; the middle, of outcrops of tertiary formations. In some places, petroleum is found on the surface of acid springs, and the earth is so charged with bitumen as to be used for fuel. There are fertilizing marls and gypsums, brown coal or lignite in beds of 6 in. to 8 ft., and beds of hematite. Beyond the tertiary lies a wide range of eretaceous formations, beds of limestone, sandstone, clays, marls, and beyond these, 5,000 sq.m. of coal-measures, four distinct seams, of 8 or 9 ft. in all, resting on fire-clay. There are also fine marbles, and some deposits of lead and copper. The soil is of great fertility, the coast producing the finest cotton, sugar, etc.; and the interior, wheat, Indian corn, tobacco, fruits of all kinds, with abundant pasture—making it one of the finest cattle-countries in the world. The climate is pure, temperate, and remarkably salubrious. The thermometer ranges from an average of 84° F., the hottest month in summer, to 50°, the coldest month in winter. The eastern region is rainy; the middle, moderate; the south-western, dry. The vegetation is in the greatest variety, from the oak, cedar, and pine, to the palmetto, muskeet, and nopal, which feeds the cochineal insect, with figs, oranges, grapes, vanilla, and flowers in wonderful profusion. The prairies abound in buffalo, immense herds of wild horses, and the forest with deer. There are also the puma, jaguar, black bear, wolf, etc. The coasts, bays, and rivers abound in the finest fish, shell-fish, turtles, etc. Though the country is generally level, it is not destitute of wild and grand scenery. In some places are found gigantic animal fossils and silicified trees. In 1870 there were 2,964,836 acres under cultivation, producing 20,554,538 bush. of Indian corn, 415,142 bush. of wheat, etc. The live-stock included, in 1873, 718,247 horses, 3,175,682 cattle, and 1,476,844 sheep. In 1870 there were in all 2,399 manufacturing establishments in Texas. There is a large trade with Mexico, and by the Red river and gulf with New Orleans. The chief exports are cotton, sugar, tobacco, cattle, and wool. The state deaf and dumb, orphan, blind, and lunatic asylums have each an endowment of 100,000 acres of state lands. In 1874 there were 2,129 public schools in Texas, and there is a state school-fund of \$2,637,673. The value of assessed property in 1875 was \$241,841,860. In 1872 there were 916 m. of railway completed; in 1875, 1572 miles.

La Salle, the French explorer, erected a fort on Matagorda bay, 1687. A Spanish settlement and mission was formed in 1690, but soon abandoned. In 1715 the country was settled by the Spaniards, under the name of New Philippines, and several missions established; but the Comanche and Apache Indians, among the most warlike in America, and still the terror of the border settlements, hindered the progress of the country. In 1803, when Louisiana was ceded by France to the United States, Texas, claimed by both Spain and the United States, became a disputed territory. From 1806 to 1816, settlements were formed, and several attempts made to wrest the country from Spain. In one of these, in 1813, 2,500 Americans and Mexicans were killed, and 700 inhabitants of San Antonio. Mina, a Spanish refugee, gained some successes, but was defeated and shot. Lafitte, a gulf pirate, made a settlement at Galveston in 1815, but it was broken up in 1821. In 1819 the river Sabine was established as the boundary. In 1820 Moses Austin, an American, got a large grant of lands in Texas from the Mexican government, and began a settlement, which rapidly increased; but many of the settlers were of so lawless a character that, in 1830, the government forbade any more Americans coming into Texas. In 1833 a convention of settlers, now 20,000 in number, made an unsuccessful attempt to form an independent Mexican state; and in 1835, a provisional government was formed, Sam Houston (q.v.) chosen commander-in-chief, and the Mexicans driven out of Texas. Santa Anna, president of Mexico, invading the country with an army of 7,500, after some successes, was entirely routed at San Jacinto, April 21; and Texas became an independent republic, acknowledged, 1837, by the United States, and in 1840 by England, France, and Belgium. In Dec., 1845, Texas was annexed to the United States, but was invaded by Mexico, which had never acknowledged its independence, and thus originated the war with the United States. In Feb., 1861, Texas joined the secession. Not till 1870 was the state readmitted to representation in congress, and regular civil government restored. In 1876 a new constitution was adopted by the vote of the people.

TEXAS (*ante*) may be divided into four sections, eastern, central or middle, western, and northern Texas. The first embraces the territory between the Sabine and Trinity rivers and is the great lumber region of the state. The soil of the uplands of this portion has a light, loamy texture on a basis of red or yellow clay; in the valleys it

is generally a deep vegetable mold or alluvium, very rich and productive. The second division lies between the Trinity and Colorado rivers and contains a large portion of the wheat lands of the state and extensive prairies. The western part includes a vast territory from the Colorado to the Rio Grande river, about four-fifths of which is prairie land and used extensively for stock raising. The northern division contains the four counties s. of Red river, is about equally divided between prairie and forest, and has a yellow, loamy, sandy soil. The principal geological formations are the alluvial, tertiary, cretaceous, and carboniferous. The alluvial extends along the gulf coast; back of this is the tertiary, having its widest expansion in the east; next, in the n.w. is the cretaceous, extending w. on Red river and s. to San Antonio. The carboniferous formation extends through the counties w. of Cooke county to the "staked plain," stretching s. from Red river to and beyond the upper Colorado. Copper is the most abundant metallic product, and a belt of the ore extends from the Red river and the counties of Clay, Archer, etc., across to the Rio Grande through Pecos and Presidio counties. Iron, lead, silver, and bismuth are also known to exist in the interior of the state. The large coal-field, mentioned above, is an outlying spur of the great Missouri coal-field, and yields a bituminous coal having 52 per cent of fixed carbon. A smaller coal-field in Brown, Coleman, Comanche, and Hamilton counties is anthracite or semi-anthracite of good quality. In the n.w. salt springs and salt lakes are numerous, and along the gulf shore, especially south-westward, there are extensive and productive salt lagoons. Potter's and fire clays, marble, roofing-slate, grindstones, soapstones, feldspar, alum, antimony, arsenic, mineral oils and pigments, marls and other fertilizers, are found in great quantities here and there. The soil, of which they are three or four varieties, is in general very fertile. The stiff, black soil of the river bottoms is fittest for sugar and cotton, though the latter grows well on the prairies and uplands; the finer black or chocolate colored soil of the prairie lands yields abundant crops of corn and the cereals, and the lighter copper colored soil of the uplands is well adapted for the grasses and fruits; while the fine silt of the islands produces the best sea-island cotton known. The soil of the desert tracts of the n.w. is sandy and charged with carbonate of soda and other alkalies, which when irrigated produces moderate quantities of grasses and herbage. The principal forest trees, of some of which several species occur, are the oak, elm, maple, hickory, pecan, sycamore, magnolia, willow pine, cypress, mulberry, cedar, sweet gum, ash, walnut, palmetto, cottonwood, and mezquite. The n. and n.w. has a temperate climate, and the gulf coast a semi-tropical. In the northern parts of the state wheat, barley, oats, corn, and cotton are the staple products, while sweet and Irish potatoes and other vegetables common in temperate climates are raised to considerable extent. Apples, pears, peaches, plums, grapes, and strawberries are also cultivated. Along the gulf the orange, lemon, olive, fig, and other semi-tropical fruits thrive. Sugar cane is raised in this region in profitable quantities, and also rice. Tobacco is cultivated to some extent both at the n. and south.

The most populous portions of the state are the eastern and central parts. In 1870 there were few inhabitants w. of the 100th meridian, except along the Rio Grande. Of the total population 756,168 persons were natives and 62,411 of foreign birth. The most of the foreigners were natives of Germany, England, or France. At that time 237,126 persons, 10 years old and upward were engaged in occupations, of which 166,753 were employed in agriculture, 40,882 in professional pursuits, 13,612 in trade and transportation, and 15,879 in manufactures and mining. By the last census, 1880, the total pop. is 1,592,574, showing a gain during the past 10 years of over 700,000. Those born in the United States number 1,478,053; in foreign countries, 114,516; those that are white, 1,197,499, the colored, 394,001. Within the past five or six years the state has been growing in popularity with emigrants, and has multiplied in prosperity in many ways. The only definite statistics at present obtainable, however, further than given, are those of 1870. The crops for that year were 66,173 bushels of spring wheat, 348,939 of winter wheat, 20,554,538 of Indian corn, 762,663 of oats, 44,351 of barley, 28,521 of rye, 44 of buckwheat, 42,654 of peas and beans, 208,383 of Irish potatoes, 2,188,041 of sweet potatoes, 7 of clover seed, 497 of grass seed, 2 of flax seed, 63,844 lbs. of rice, 59,706 of tobacco, 1,251,328 of wool, 3,712,747 of butter, 34,342 of cheese, 51 of hops, 25 of flax, 13,255 of wax, 275,169 of honey, 6,216 gallons of wine, 5,032 of maple molasses, 174,509 of sorghum molasses, 246,062 of cane molasses, 2,020 hogsheds of cane sugar, 5 tons of hemp, 18,982 of hay, and 350,628 bales of cotton. Of the manufactured products at that date the most important was lumber, there being 192 saw-mills, producing annually material valued at \$1,736,482. Next in importance and value were the packing establishments of beef and other meats, in fifteen of which packed meats, condensed meat essences, meat biscuits, etc. were put up to the value of \$1,052,156. Among the other manufactories were 4 cotton-mills that produced goods annually valued at \$375,000; 138 saddlery and harness establishments; 71 tin, copper, and sheet-iron ware factories; 115 carriage and wagon shops; 533 flouring and grist mills; and 12 establishments for the manufacture of agricultural implements. Altogether the capital invested amounted to about \$5,281,110; the wages paid, \$1,787,835; the value of raw material \$6,273,193; and the value of goods produced, \$11,517,302. The abundance of raw material, the water-power of the w. central region, and the high price of manufactured goods have stimulated these industries a great deal, and manufacturing since

1870 has made much progress. A large part of the state's trade is with Mexico, and the chief item of export is cotton. The ports of entry are Brownsville, Corpus Christi, El Paso, Indianola, and Galveston. For the year ending in June, 1875, the imports amounted to \$3,950,239; the exports of domestic products, \$17,193,118; the exports of foreign products, \$1,631,054. The principal railroads are the Houston and Texas Central, extending from Houston to Red river, 340 m.; the International, from Hearne to Longview, 174 m.; the Houston and Great Northern, from Houston to Palestine, 152 m.; the Galveston, Harrisburg and San Antonio, from Harrisburg to Columbus, 84 m.; the Texas Pacific, from Longview to Shreveport, La., 66 m.; and the Gulf, Houston and Henderson, from Galveston to Houston, 50 miles. The national banks in 1875 numbered 10, and the state banks 20.

In Feb., 1876, the bonded debt of the state was \$4,249,757 and the floating debt, \$543,137, making an aggregate of \$4,792,894. The receipts from all sources, including a balance in the treasury from Aug. 31, 1874, to the same date 1875, the close of the fiscal year, were \$2,890,075, and the disbursements for the same period were \$2,497,276, leaving a balance in the treasury of \$392,799.

The public schools of the state are under the control of a board of education composed of the governor, comptroller, and secretary of state. The permanent fund in 1875 amounted to \$2,637,673, and the constitution provides that one-fourth of the revenue from general taxation and a poll tax of \$1 shall be annually set aside for school purposes. In addition to these resources the Peabody fund paid in 1875 \$4,800 in aid of the public schools. The school population during that year in 145 counties was 331,400 children. Only 97 counties, however, made any definite report, in which the school population was 210,922. Of these 124,567 were enrolled in the schools, and the average daily attendance was reported to be 84,415. There were about 2,924 organized schools and 3,190 teachers employed. Among the collegiate institutions in the state at that date were Baylor university (Baptist), at Independence; Austin college (Presbyterian), at Huntsville; university of St. Mary (Roman Catholic), at Galveston; Soule university (M. E. south), at Chappell Hill; Trinity university (Cumberland Presbyterian), at Toluca; Henderson college (non-sect.), at Henderson; and Texas university (M. E. south), at Georgetown. Most of these schools have several departments and admit both sexes. The number of libraries in 1870 was 455 with 87,111 volumes, of which 135 with 25,018 volumes were public. The newspapers and periodicals published number about 129, of which 12 are daily, 49 weekly, and 1 semi-monthly. The religious organizations in 1870 were 275 Baptist, 18 Christian, 1 Congregational, 32 Episcopal, 1 Jewish, 23 Lutheran, 355 Methodist, 101 Presbyterian, and 36 Roman Catholic.

A new constitution, adopted Feb. 15, 1876, fixes the term of the governor and most of the executive officers at two years. The legislature meets biennially, and consists of a senate of 31 members and a house of representatives of 93 members. Judicial officers are elected and serve for limited terms. Voters must have resided one year in the state and six months in the district where the vote is cast; and if financial measures are voted upon, tax-payers alone are allowed to vote. By the apportionment of 1872 the state is entitled to six representatives in congress and eight electoral votes. The electoral votes have been cast as follows: 1848, Cass and Butler, 4; 1852, Pierce and King, 4; 1856, Buchanan and Breckenridge, 4; 1860, Breckenridge and Lane, 4; 1864 and 1868 no vote was cast; 1872, Greeley and Brown, 8; 1876, Tilden and Hendricks, 8; 1880, Hancock and English, 8.

TEXAS, a co. in s. Missouri, drained by Current river, and the branches of the Gasconade river; about 1225 sq.m.; pop. '80, 12,219—12,024 of American birth. The surface is hilly and heavily wooded. The soil in the river valleys is rich. The principal productions are corn, wheat, tobacco, oats, wool, and cattle. Co. seat, Houston.

TEXAS CATTLE DISEASE, otherwise called Spanish fever, splenic fever, acclimation fever, American cattle plague, red water, black water, yellow murrain, and bloody murrain; a very fatal epizootic, contagious or infectious fever of cattle, confined to regions s. of the 37th parallel of n. latitude except when communicated by cattle brought from there. The earliest recorded account of the disease is in a lecture before the "Philadelphia Society for Promoting Agriculture" by Dr. James Meare, Nov. 3, 1814, and which is quoted in a report to the department of agriculture at Washington in 1871 on diseases of cattle in the United States by Mr. Dodge. It is there stated that cattle from certain districts in South Carolina were found to communicate the disease to those with which they mingle while being driven northward, and that a law was enacted by Virginia against their passing through that state. At the session of the general assembly of North Carolina in 1836-37, a law was passed to prevent cattle from entering that state from either South Carolina or Georgia between the first of April and the first of November. At the session of 1873-74 a new law was passed prohibiting the driving of cattle from South Carolina or Georgia into any of the counties w. of the Blue Ridge between the first day of April and the last day of November, and at the session of 1878-79 the former law was altered so as to prohibit the driving of cattle, not only from South Carolina and Georgia, but from any of the counties e. of the Blue Ridge, and also extending the prohibition to *all seasons of the year*. The greatest losses have been caused by driving Texas cattle through Arkansas, Missouri, and Kansas, and distributing them to feeders in vari-

ous western states. Missouri suffered much in this way as long ago as 1852 and 1853, and in the summers of 1856 and 1857 the states of Kansas and Iowa had great numbers of cattle swept away by the disease which was communicated by southern droves. In 1866 a drover brought a steamboat load of Texas cattle up the Mississippi and Ohio rivers, landing them at Louisville and driving them to Lexington, Ky., and all along the route of the drive nearly all the native cattle perished, and of a drove of fat cattle which followed them, all took the disease and died. In 1867 Cairo, Ill., became the chief point of transshipment of cattle coming from Texas and other places in the s., in consequence of their being prohibited from passing through Kansas, Missouri, and Iowa. During the early part of the season there was no trouble, but with the warm weather the disease made its appearance. In 1868 there was a great outbreak. Large numbers of cattle were brought into the state of Illinois. At the little town of Tolono, at the crossing of the Illinois Central and Toledo and Wabash railroads, from fifteen to eighteen thousand Texas cattle were landed, which by the first of September occasioned the death of nearly one thousand native cattle of the township, and five thousand in the county. Nearly two thousand cattle were carried off by the disease near Loda, Ill., and many others in different parts of the state. The losses in Warren co., Ind. alone were reported to be over fifteen hundred. At Cincinnati, Ohio, a herd of twenty-nine cows exposed to the contagion, all died, and similar experiences were repeated in other sections.

All observations indicate that in the permanently infected districts s. of parallel 37° the cattle become accustomed to the influence of the disease germs, and that the effect is much milder upon the organization, passing through it without creating much disturbance, and generally without being noticed. When, however, the southern cattle are taken into regions previously unaffected the native cattle, not being protected by previous habitual exposure, become the victims of the disease. The imported droves, also, when crowded, suffer to a certain extent, but not in comparison with the native cattle. Native cattle have been known to convey the disease to native cattle in other states, one instance being where native cows from Painesville, Ohio, brought the disease to Orange co., N. Y., causing the death of eight animals. *Symptoms.*—One of the first symptoms is an elevation of the animal temperature, which ranges usually from 106° to 105° Fahr. but occasionally not more than 104° to 105°, and sometimes as high as 110°. As death approaches the temperature falls to below the normal. The first outward symptoms are those of languor and fatigue, as drooping of the head, lopped ears, and arching of the back. The eyes are staring, the coat rough, the horns are hot and the nose dry. As the disease advances the head droops more, so that the nose almost reaches the ground; the hind legs are placed far under the body; the legs are very weak and the animal has a disposition to lie down, especially in water. The pulse is very frequent; sometimes soft and feeble, but often hard and wiry. The post mortem appearances are only to be seen soon after death, as decomposition rapidly sets in and speedily obliterates the pathological conditions. When soon enough examined the muscles have a dark red color, and the fat is of a deep brownish yellow, in some cases having a bronzed appearance. All the tissues, but particularly the muscles, have a peculiar sickening odor. On examining the alimentary canal the œsophagus and the first three stomachs have generally a not unnatural appearance, although the third stomach is often found dry and obstructed. In the fourth stomach there are characteristic changes. The whole mucous membrane is more or less congested, the cardiac portion especially, but the more peculiar lesions are at the pyloric end. It is not so much discolored, but is full of erosions, sloughs, and deep, excavated ulcers. The small intestines are the seat of congestions. Engorgements and extravasations of blood are common in the large intestines. The liver is usually enlarged, sometimes weighing from twenty to twenty-seven pounds, and fatty or waxy. The bile-ducts are injected with a yellowish-brown bile, and the gall bladder is almost always distended, with a dark, thick, flaky, and tarry looking bile, sometimes amounting to as much as four pounds. The kidneys are usually congested and enlarged, and the cortical substance softened. In a few cases they have a healthy appearance. The urinary bladder is generally distended with dark bloody urine, and the mucous membrane is frequently thickened and inflamed. The spleen is always enlarged, and engorged with dark colored blood. It is frequently softened, and in some cases is a mere pulpy, disorganized mass. It has been found two feet and a half long, and having a weight of over nine pounds. The lungs are generally healthy in appearance with the exception of small points of extravasation, and enlargement of some of the air-cells. The blood in the blood-vessels is nearly natural in appearance and coagulates quickly, but is generally rather more watery than in health. Dr. J. Cresson Stiles found that the white corpuscles were in excess only in one case, but the liquor sanguinis was yellow lower than in health, and contained minute flocculi of yellow granular matter. In some instances complete dissolution of the blood globules took place long before putrefaction. There is considerable difference of opinion as to the cause of the disease, and the nature of the infectious principle, but the general opinion is that it is owing to the development of a disease germ. The period of incubation varies. All observers agree that it is always as much as ten days, but it is often from two to six weeks, and even longer. It has been supposed by some that the period depends upon the amount of contagious matter present, but instances of the disease being propagated rapidly where cattle have been turned into pasture which had been but a short time occupied by only

a few imported cattle disproves this theory. Prof. Law of Cornell university, regards the virus as not being diffused in the atmosphere, but confined to the pastures on which the southern cattle graze, and he instances the fact that cattle may occupy a field adjacent to one in which southern cattle have grazed without taking the disease. In regard to extermination he regards the affection as of much less importance than pleuro-pneumonia (q.v.). The chief measures against the disease are those of prevention, and these consist in preventing the introduction of southern cattle during the spring and summer months, and the use of disinfectants in places where they have been harbored; but the efficacy of the latter is to great extent doubtful on account of the difficulty of thorough application. Considerable investigation is needed, and stringent measures of exclusion resorted to before satisfactory results can be attained.

TEXEL, **TIE**, an island in the province of n. Holland, separated from the Helder by a narrow strait, called the Marsdiep, contains about 35,000 acres of arable and pasture lands, and has a pop. of 6,408. Many sheep are kept, producing fine wool. Fishing, ship-building, grinding corn, etc., are also sources of prosperity. There is much wealth in the island, but recently no steamboat communication existed with the mainland. The northern part is called Eijerland, or the egg-country, immense flocks of birds coming thither from Scandinavia to deposit their eggs.

TEXTILE FABRICS. See **WEAVING**.

TEZCU CO (i.e., "place of detention"), an ancient and much decayed city of Mexico, stands on the e. shore of the lake of the same name in the state, and 16 m. e.n.e. of the city of Mexico. In former times it was the capital of a great state, and was the second city in Mexico. During the early part of the 15th c. the city rose to its greatest splendor. It then contained ranges of stately mansions, in which the nobles resided, and a magnificent and vast pile of buildings, which served as the royal residence and as public offices. Tezcuco is now a poor place, filled with heaps of rubbish and ruins, and containing only 5,000 inhabitants.

THACHER, JAMES, 1754-1844; b. Mass.; served as surgeon's mate in the revolution to Dr. John Warren, at the hospital in Cambridge, Mass., 1778; chief surgeon to the 1st Virginia regiment in 1779; and later to a New England regiment. He settled in Plymouth, Mass., in 1783, as a physician, and became interested in the manufacture of salt and iron. He published various medical works; also agricultural and historical books.

THACHER, PETER, D.D., 1752-1802; b. Mass.; graduated Harvard college, 1769; ordained minister of Malden, 1770; wrote *Narrative of the Battle of Bunker Hill*; was a delegate to the state constitutional convention of 1780; was often chaplain to the legislature; pastor of Brattle Street church, Boston, 1785, remaining until his death. He was distinguished for pulpit eloquence, receiving the name of the "silver-tongued Thacher." He was a member of the American academy of arts and sciences. He published 22 works, among which were *Observations on the State of the Clergy in New England*.

THACHER, THOMAS, 1620-78; b. England; came to Boston, 1635; studied under Dr. Chauncy; ordained minister of Weymouth, Mass., 1645; practiced medicine in Boston, 1661; became the first pastor of Old South church, 1670, and remained until his death. He published *A Brief Rule, etc., in Small-Pox and Measles*, the first medical treatise published in New England. He prepared a *Hebrew Lexicon*, which was not printed.

THACKERAY, ANNE ELIZABETH, b. England, 1842; daughter of William Makepeace. Besides many less pretentious books, she has written *The Story of Elizabeth* (1863); *Old Kensington* (1873); and *Miss Angel* (1876); all novels marked by delicate perception and considerable powers of description.

THACKERAY, WILLIAM MAKEPEACE, novelist and satirist, was b. at Calcutta in 1811. He was of a good old English family, represented about the middle of last century by Dr. Thackeray, an eminent scholar, and head-master of Harrow. His father was in the civil service of the East India co., and, dying young, he left his son a fortune of £20,000. The latter, when a boy seven years of age, was sent to England, and placed in the Charterhouse school, that ancient Carthusian foundation, which he loved to commemorate in his writings. He next went to Cambridge, but left the university without taking a degree. In 1831 he was at Weimar, and saw Goethe. His ambition was to become an artist, and he traveled over most of Europe, studying at Paris and Rome. His drawings were not without merit; they were quaint, picturesque, and truthful, but somehow they missed the bright touches of a master-hand. He next took to literature, beginning with rare patience and contentment at the lowest step of the ladder. Under the characteristic name of Michael Angelo Titmarsh, or that of Fitz-Boodle, he became a constant contributor to *Frazer's Magazine*, and wrote for it two of the best of his minor works, *The Great Hoggarty Diamond* and *Barry Lyndon*. The latter is the story of an Irish sharper, and is told with a spirit, variety of adventure, and humor worthy of Le Sage or Fielding. Under the pseudonym of Titmarsh he also published *The Paris Sketch-Book* (2 vols. 1840); *The Second Funeral of Napoleon*, and *Chronicle of the Drum* (1841); and the *Irish Sketch-Book* (2 vols., 1843). The greater part of Thackeray's fortune having been spent in foreign travel and unsuccessful speculations at home, he continued to work steadily at literature as a profession. He was never widely popular, but a few

good judges appreciated his keen wit, observation, and irony, and his command of a style singularly pure, clear, and unexaggerated. The establishment of *Punch* afforded a more congenial field for Thackeray, and *Snob Papers* and *Jeames's Diary* were hailed with delight by all readers. Their author's reputation was still more advanced by his novel of *Vanity Fair* (1846-48), published in monthly parts in the style of *Pickwick*, and illustrated by the novelist himself, or, as he expressed it, "illuminated with the author's own candles." During the progress of *Vanity Fair* appeared *Notes of a Journey from Cornhill to Grand Cairo*, being an account of a journey undertaken for the benefit of his health; also *Mrs. Perkins's Ball*, a short Christmas tale, and two works of a similar kind entitled *Our Street*, and *Doctor Birch and his Young Friends*. In 1849 he began a second serial fiction, *Pendennis*, in which much of his own history and experiences are recorded. Next followed *Rebecca and Ronceni* (1850), and *The Kickleburys on the Rhine* (1851). The latter work was sharply criticised by the *Times*, and Thackeray replied in a caustic and humorous *Essay on Thunder and Small Beer*, prefixed to a second edition of the satirical sketch. In 1851 the indefatigable novelist delivered a course of lectures on the *English Humorists of the Eighteenth Century*—light, graceful, discriminating sketches, with passages of real power and eloquence. In 1852-55 appeared two more novels, the most richly imaginative and highly finished of his works, *Esmond* and *The Newcomes*. These were followed by *The Virginians* (a much inferior novel), by *Lectures on the Four Georges* (first delivered in America), by *Lovel the Widower* and *Philip* (two short tales of somewhat coarse texture), and by a series of pleasant gossiping essays, entitled *Roundabout Papers*. These originally appeared in the *Cornhill Magazine*, of which Thackeray was for a time editor; and in the same miscellany he had begun and published part of a new novel, *Dennis Duval*, which promised to be one of the most carefully elaborated and successful of his works of fiction. He contemplated also *Memoirs of the Reign of Queen Anne*, which would have served as a continuation to Macaulay's *History*. He knew that period well, from his previous studies for *Esmond*, and as a moral anatomist and master of English he stood unrivaled. But, alas! such dreams and anticipations were suddenly dispelled. To the grief of all lovers of genius and of manly and noble character, Thackeray was cut off in the fullness of his powers in his 53d year, dying alone and unscen in his chamber before daybreak on the morning of Dec. 24, 1863. His medical attendants found that death was caused by effusion on the brain, and that his brain was one of the largest, weighing no less than 58½ ounces.

In his delineation of the character and genius of Fielding, Thackeray has drawn his own. He had the same hatred of all meanness, cant, and knavery, the same large sympathy, relish of life, thoughtful humor, keen insight, delicate irony, and wit. There was, however, one personal difference: Fielding was utterly careless as to censure of his works, whereas his successor was tremblingly alive to criticism, and was wounded to the quick by the slightest attack. His morbidly delicate organization made him exquisitely susceptible of either pain or pleasure. He had suffered much from physical maladies and from domestic calamity; and his earlier works, especially his *Vanity Fair*, were tinged with a degree of cynicism which seemed to countenance the charge of his unfriendly critics, that he delighted in representing the baser side of human nature, and was skeptical as to the existence of real virtue in the world. His strength lay in portraying character rather than inventing incidents; and in Becky Sharp, col. Newcome, Harry Foker, Laura Pendennis, and Paul de Florae, to say nothing of the picaresque, Barry Lyndon, he has left us a living gallery, certainly not surpassed by any modern novelist. In his later writings the dark shades no longer preponderate. The mellowing influence of years and sickness, and calmer as well as more extensive observation of life, had sunk the merciless satirist in the genial humorist and philosophic observer. He had still ample scorn for falsehood and vice, and satire for folly and pretense; but he had also smiles and tears, and tenderness and charity, that gave a moral beauty and interest to the last decade of his brilliant career as an author.

THAIS, an Athenian courtesan, famous for her wit and beauty, who was in Asia along with Alexander the great, and according to Cleitarchus—a doubtful authority—induced the Macedonian king, when excited with wine, to set fire to the palace of the Persian kings at Persepolis. After his death she lived with Ptolemy Lagi, by whom she became the mother of several children.

THALASSIDROMA. See PETREL.

THALBERG, SIGISMUND, a very eminent pianist, b. at Geneva in 1812, received the greater part of his musical education at Vienna, where he was a pupil of Hummel. He made his first public appearance in 1827, and his *début* in Paris in 1835. After residing for a time in America he returned to Europe, and died April 27, 1871. In graceful and brilliant execution, and in manual dexterity on the piano, he had hardly a rival. His compositions are principally fantasias and variations.

THALEIA, or **THALIA** (Gr. the blooming one), one of the nine muses (q.v.), generally regarded as presiding over comedy. By Apollo, Thaleia became the mother of the Corybantes.

THALER, a coin in circulation in Germany, Austria, Holland, Belgium, Denmark, Sweden, and Norway. The new German *thaler* of silver is worth \$0.729, the specie

daler of Norway is equal to \$1.107, the *ten-thaler* (gold) of Denmark is worth \$7.861. The value varies in different parts of Germany; the Russian *thaler* is worth 71 cents. The word *thaler* is thought by some to be taken from the name of a mining town in Bohemia, called Joachimsthal (Joachim's dale), in which these pieces were coined, and that they were first known as *Joachimsthaler* and then for brevity *thaler*. German scholars derive the term *thaler* from *talent*, signifying a pound of gold. In the early part of the 16th c. the silver coins in use at Joachimsthal weighed 1 ounce. In Sweden the *rigsdaler riksmunt* is about 27 cents. In Denmark the *rigsbank daler* is about 54 cents. In Germany generally the *thaler* of account is from about 69 cents to 73 cents, American currency. In other countries the *Loeffthaler* or leaf dollar is in use; the *Pfennigthaler*, the Swedish copper dollar, and in Spain the *dalcra*, the Spanish pillar dollar, which was taken as the basis of the United States coinage and money of account. In most European countries the mints have coined *thalers* (varying in value with the locality), hence called *rigsdaler* or *reichsthaler*, the dollar of the realm.

THALÉS, an early Greek philosopher, founder of the Ionic or physical school of philosophy, and one of the seven wise men (q.v.), was a native of Miletus, in Asia Minor, and flourished toward the close of the 7th c. B.C. Very little is known regarding his life. He is said to have recommended the Ionians, who were menaced by the Persians, to form a federation against their powerful enemy, and to select Teos as the capital. At a later period, we are told he induced the Milesians to withdraw from a union with Croesus against Cyrus. He is also said to have predicted the eclipse of the sun which happened in the reign of Alyattes. His claim to the title of sage (as in the case of his competitors) was due to his practical wisdom rather than to his speculative achievements. Nevertheless, Thales has a name in the history of speculative philosophy. He is even regarded by some as the *first* Greek that speculated on the constitution of the universe. According to him, the original principal of all things is water, from which everything proceeds, and into which it is again resolved. It would appear also that in connection with this doctrine he had some idea of a soul or force in water productive of all the phenomena we see, but it is impossible to ascertain the extent of his belief in an immaterial power. Most probably, his philosophy was a form of pantheism, rather than of theism. None of Thales' speculations were committed to writing, and it is only from the notices of later Greeks, such as Herodotus, Aristotle, etc., that we can gather an idea of the character of his thinking.—See Ritter's *Geschichte der Ionischen Philosophie* (Berl. 1821), Lewes's *Biographical History of Philosophy*, and prof. Ch. A. Brandis, in Smith's *Dic. of Gr. and Rom. Biog.*, art. "Thales."

THALLIUM (symb. Tl, equiv. 204, spec. grav. 11.9) is a metal which derives its name from the Greek word *thallos*, green, because its existence was first recognized by an intense green line appearing in the spectrum of a flame in which thallium is volatilized. It was discovered by Mr. Crookes, the editor of the *Chemical News*, in 1861, in the seleniferous deposit of a lead chamber of a sulphuric acid factory in the Hartz mountains, where iron pyrites is employed for the production of the acid. In the following year, it was obtained in larger quantities from a similar source by M. Lamy, who exhibited magnificent specimens of it in solid bars at the last great exhibition in London. Thallium is slightly heavier than lead—a metal which it resembles in its physical properties. It is very soft, being readily cut with a knife, or drawn into wire; and its freshly-cut surface exhibits a brilliant metallic luster and grayish color, somewhat between those of silver and lead. In contact with the air, it tarnishes more rapidly than lead, and becomes coated with a thin layer of oxide, which preserves the rest of the metal. It fuses below a red heat, and is soluble in the ordinary mineral acids. With oxygen, it enters into two combinations—viz., *Oxide of Thallium*, which is a strong base, forming well-defined salts with acids; and *Thallie Acid*, which is soluble in water, may be obtained in crystals, and forms soluble salts with the alkalis.

There is a difference of opinion as to whether the salts of thallium are or are not powerful irritant poisons. Lamy (with the view of testing the statement of Paulet, that the salts are poisonous) dissolved 75 grains of the sulphate in milk; and he found that this quantity sufficed to destroy two hens, six ducks, two puppies, and a middle-sized bitch. In one experiment, a grain and a half proved fatal to a puppy. Mr. Crookes, on the other hand, although much exposed to the fumes of this metal, suffered no particular effects from them; and he swallowed a grain or two of the salts without injury. He found that the latter have a local action on the hair and skin, staining the former, and rendering the latter yellow and horny.—For further details regarding this metal, the reader may consult Mr. Crookes's memoirs in the *Philosophical Transactions* for 1862, and in the *Chemical News*, and Lamy's memoir in the *Annales de Chimie et de Physique* for 1863.

THALLOGENOUS PLANTS are those acotyledonous plants which exhibit the greatest simplicity of structure, consisting of a mere thallus (q.v.) with reproductive organs. Of this description are *algæ*, *characeæ*, *fungi*, and *lichens*. When apparent leaves exist in any of these, they do not exhibit the symmetry always found in true leaves; and although some of them have stems or stalks, which attain, as in some sea-weeds, both to a considerable age and to great strength, all is composed of cellular tissue without any proper woody fiber.—In the botanical system of Lindley, the thallogenous

plants form a class, under the name *thallogens*; and in that of Endlicher, a corresponding place is assigned to them under the name *thallophyta*.

THALLUS, in botany, a structure composed of cellular tissue, without woody fiber, which in some of the lower cryptogamic orders, as *algæ*, *fungi* and *lichens*, constitutes the whole plant, except the reproductive organs, which are situated in or upon it. The thallus assumes very various forms, sometimes crust-like, sometimes spread out like a leaf, simple, lobed, or branched; or, as in mushrooms, it becomes a stalk, cap, and gills.

THAMES, a river formed by the union, at Norwich, Conn., of the Yantic, Quinebaug, and Shetucket rivers. The course of the river is s., and it enters Long Island sound 3 m. below New London and 15 m. from the junction of the three rivers. The river, a picturesque tidal channel, is navigable for its full course, and its mouth forms New London harbor.

THAMES (Lat. *Tam-esis*; the root *tam* probably meaning broad, and *esis* or *isis*, being identical with *esk*, *ex*, *ouse*, etc., all from Cel. *uisg*, water), the most important river of Great Britain, and the longest in England, flows e.s.e. across the s. portion of the country. Its remotest springs—those of the upper waters of the Churn—rise on the s.e. slope of the Cotswold hills, 3 m. s. of Cheltenham, and 7 m. w. of the Severn at Gloucester. The springs unite about a m. from their sources, and form the Churn, which flows s.e. 20 m. to Cricklade, and there receives the Thames, which joins it from the w. after a course of 10 miles. The Thames, or Isis, then flows e.n.e. for about 35 m., when, curving s.e., it passes Oxford, and flows on to Reading, where, after receiving the Kennet from the w., it again changes its course; and with a generally eastward course, it passes Windsor, Eton, Richmond, London, Woolwich, and Gravesend, a few miles below which it expands into a wide estuary, and enters the North sea. The length of the Thames is estimated at 250 m., the area of its basin at upward of 6,000 sq. miles. Throughout the greater part of its course, it is of importance as forming the boundary-line between several of the southern counties. Passing Cricklade, it forms part of the northern boundary of Wilts, and below this point it separates the counties of Oxford, Buckingham, Middlesex, and Essex on the n. from those of Berks, Surrey, and Kent on the s., except certain outlying bits of some of these counties. Its chief affluents are the Coln, Leach, Windrush, Cherwell, Thame, Colne, Lea, and Rothing, on the left; and the Kennet, Loddon, Darent, Mole, and Medway, on the right bank. At Vauxhall bridge, the width of the river is about 220 yards; at London bridge, 290 yards; at Woolwich, 490 yards; at Gravesend pier, 800 yards; 3 m. below Gravesend, 1290 yards; and at its mouth, between Whitstable and Foulness Point, about 8 m. below the Nore, it is 18 m. across. At the Nore Light, the commonly reputed mouth of the Thames, the breadth is 6 miles. The river is navigable for barges to Lechlade, upward of 200 m. above its mouth, and it is connected with the Thames and Severn, Oxford, Wilts and Berks, Grand Junction, and several other important canals, by means of which it maintains free communication with the w. and s. coasts, and with all parts of the interior of the country. Vessels of 800 tons can reach St. Katharine's docks, while those of 1400 tons can ascend to Blackwall, 6 m. below London bridge. The part of the river immediately below London bridge is called the *Pool*; and the part between the bridge and Blackwall is called the *Port*. Two embankments have been formed, one on the n. shore from Blackfriars bridge to Westminster, and one on the s. shore from Westminster bridge to Vauxhall. See LONDON.

THAMES, BATTLE OF THE, at the Moravian settlement on the Thames river, Ontario, Can., Oct. 5, 1813; between the American forces under gen. William H. Harrison, and the British under gen. Proctor with 2,000 Indian allies under Tecumseh. Tecumseh was killed during the battle. The charge of the cavalry under col. Richard M. Johnson began and decided the battle, in which 600 British prisoners were taken, besides, stores, cannon, etc. See TECUMSEH, and HARRISON, WILLIAM HENRY.

THANATICI is the term used by the superintendent of the statistical department in the registrar-general's office, Dr. Farr, in his *Nosology*, to indicate "lesions from violence tending to sudden death." These lesions are the direct results of physical or chemical forces, acting either by the will of the sufferer or of other persons, or accidentally.

THANE, or **THENG** (A.-S. *thenen*, analogous to Ger. *dienen*, to serve), a title whose use in the early feudal ages has been the subject of much discussion. In England, in Saxon times, the king's thane was a "miles emeritus," who, on the cessation of his actual service about the king's person, received a benefice or grant of land. The term "miles," when used by Bede, is uniformly rendered "eyringes then" by his Saxon translator. In the 10th c., all who would, in the feudal era, have been known as tenants *in capite*, were thanes. After the conquest, thanes and barons are classed together; and in Henry I.'s time the terms seem to be used synonymously. The office or dignity appears to have been attached to particular estates; thane lands are frequently mentioned in Domesday. After the reign of Henry II., the term fell into disuse. The title thane was introduced at a later period into the northern parts of Scotland, where, however, it did not express the same rank and dignity as in England; the tenure not being military, but in fee-farm.—The Scottish thane seems to have been a hereditary tenant, paying the sum at which the land stood in the king's rental, and

retaining his ancient authority strengthened and legalized. The title was in occasional use in Scotland down to the end of the 15th century. Hector Boece's notion of the Scottish thanes being all made earls, which has been adopted in Shakespeare's *Macbeth*, is devoid of historical foundation.

THANET, ISLE OF, forms the north-eastern corner of the county of Kent (q.v.), from the mainland of which it is cut off by the river Stour and its branches, and is bounded on the n. and e. by the sea. It is 10 m. in length, and from 4 to 8 m. broad; and contains 25,500 acres, of which 23,000 are arable, and 3,500 in marsh and pastures. The surface is high, but in the main, level; the soil is in general light and chalky; the island, however, is rich and fruitful—agriculture being successfully pursued. Besides the ordinary crops, canary and radish seeds are largely grown. On the shores of the island are the well-known watering-places, Ramsgate, Margate, and Broadstairs; and on the n. foreland, in the n.e., there is a light-house, 340 ft. above sea-level, and, visible at the distance of 22 miles. Pop. (1871) 42,129.

The isle of Thanet, the British name of which was *Ruin* (a headland), was at one time separated from the mainland by a sea-passage, called the Wantsome, which in Bede's time was one-third of a mile wide, and was passable only at Sarre and Wade. The Wantsome was the general sea-passage toward London for the Danish ships, but in 1500 it became finally closed.

THANKSGIVING DAY is chiefly an American institution. After the first harvest of the New England colonists in 1621 gov. Bradford made provision for their rejoicing specially together with praise and prayer. In 1623 a day of fasting and prayer in the midst of drought was changed into thanksgiving by the coming of rain during the prayers; gradually the custom prevailed of appointing thanksgiving annually after harvest. These appointments were by proclamation of the governors of the several New England states. During the revolution a day of national thanksgiving was annually recommended by congress. Washington recommended such a day, after the adoption of the constitution, and his example was occasionally imitated by subsequent presidents. During the rebellion, pres. Lincoln frequently recommended the observance of such a day after victories, and made a proclamation for a national observance in 1863. Since that time such a proclamation has been annually issued, and custom has fixed on the last Thursday of November as the time. Of late years, the custom of appointing a Thanksgiving day by the governors of states, long confined to New England, has been adopted through the country.

THANN, a t. of Germany, in the province of Alsace-Lorraine, at the foot of a hill crowned by the ruins of the castle of Engelburg, 13 m. w.n.w. of Mulhouse. It contains a superb gothic church, surmounted by a spire of delicate open work, upward of 300 feet high. Cotton cloths, chemicals, and machinery are manufactured. Pop., '75, 7,532.

THASOS, the most northerly island in the Ægean sea, a few miles off the coast of Macedonia. Circumference about 40 miles; pop. about 5,000, scattered over a dozen villages. Thasos is mountainous, and on the whole, barren. The description of it given by Archilochus is still applicable: "An ass's backbone overspread with wild wood." It exports some oil, honey, and timber. In ancient times the island was famous for its gold mines, which appear to have been worked from a very remote antiquity, and which, immediately before the Persian wars, yielded upward of 300 talents yearly; but they have long since been abandoned. Some remains of the ancient town of Thasos still exist.

THATCHER, HENRY KNOX, 1806–80; b. Thomaston, Me., grandson of gen. Henry Knox, entered the navy as midshipman, 1823; rose through successive grades to capt., 1861; commander, 1862. He commanded the frigate *Constellation* in the Mediterranean, 1862–63, the steam frigate *Colorado*, n. Atlantic blockade squadron, 1864–65. He distinguished himself in the attacks on fort Fisher under Porter, 1864–65, and in the siege of Mobile under Farragut, co-operating with gen. Canby in 1865; receiving the surrender of the confederate naval force in Mobile bay; appointed rear-admiral, 1866, for gallantry in this action; retired, 1868; residing at Winchester, Mass., and Nahant. He was at one time commandant of the Charlestown navy-yard, a member of the Bunker Hill monument association, and pres. of the Massachusetts society of the Cincinnati; succeeding his grandfather in membership.

THAYER, a co. in s.e. Nebraska, adjoining Kansas; drained by the Little Blue river and Big Sandy creek; traversed by the St. Joseph and Denver railroad; 575 sq.m.; pop. '80, 6,113—5,281 of American birth. The surface is mostly rolling prairie. The soil is fertile. The principal productions are corn, wheat, and cattle. Co. seat, Hebron.

THAYER, JOSEPH HENRY, D.D., b. Boston, 1828; educated at Harvard college and Andover theological seminary; for a short time pastor of a Congregational church in Salem, Mass., and an army chaplain. In 1864 he became associate professor of sacred literature in Andover theological seminary, where he still (1881) remains. He has published a translation of Winer's *New Testament Grammar*, and of Buttmann's *New Testament Grammar*.

THAYER, SIMEON, 1737-1800; b. Mass.; served in the French and Indian war, 1756-57, and was taken prisoner at fort William Henry. On the outbreaking of the revolution he received a capt.'s commission, and was with Arnold in the Quebec expedition, where he was made prisoner. After his release he did gallant service at Red Bank, fort Mifflin, and the battle of Monmouth, where he was severely wounded. In 1781 he left the army. He wrote a *Journal of the Invasion of Canada in 1775*.

THAYER, SYLVANUS, 1785-1872; b. Mass.; educated at Dartmouth college and at West Point. He was appointed to the engineers, served through the war of 1812, and was chief engineer of gen. Dearborn, gen. Hampton, and gen. Porter, successively. Visiting Europe on professional duty, he witnessed the movements of the allies before Paris, and studied the military systems of France and other countries. He was superintendent of the U. S. military academy, 1819-33, and raised it to a high standing. He afterward supervised the construction of the defenses of Boston harbor. In 1857-58 he commanded the corps of engineers. He was retired in 1863, with the rank of col. He founded the Thayer school of civil engineering at Dartmouth college, and a free public library in his native town of Braintree.

THAYER, THOMAS BALDWIN, D.D., b. Boston, 1812; educated in Boston; pastor of a Universalist church, Lowell, Mass., 1833-45; and in Brooklyn, N. Y., 1845-51; returned to Lowell, 1851; settled in Boston, 1857-69. He is editor of the *Universalist Quarterly*; has published *Christianity against Infidelity*; *The Theology of Universalism*.

THEA. See TEA.

THEATER, a place for public representations, chiefly of a dramatic or musical description. Theaters are of very ancient origin. They were found in every Greek city, both at home and in the colonies, and many very interesting specimens of the Greek theaters still exist in very good preservation. These were not built like modern theaters, with tiers of galleries rising one over the other, but were constructed with concentric rows of seats rising in regular succession one behind and above the other like the steps of stairs. These seats were frequently cut in the solid rock; and a place where the natural curve and slope of the ground rendered such excavation easy, was generally chosen. The seats, or audience department, were arranged in a semicircular form. In the center, at the lowest point, stood the orchestra; and the proscenium, or place for the dramatic representation, formed the chord of the semicircular auditorium. Behind this was the scena, closing in the building was a solid wall, generally ornamented with pillars, cornices, etc. There was no roof, but the audience was probably protected from the sun's rays by a curtain stretching across the theater. This form of theater was also that adopted by the Romans, who built or excavated large theaters in many of their important towns. The theaters of the Romans differed from their *amphitheaters* (q.v.), the former being semicircular, the latter oval, and with seats all round. Of the theaters still remaining, that of Orange, in the s. of France, is one of the finest, the auditorium being 340 ft. in diameter. During the middle ages, theaters were unnecessary, and were never built. The few dramatic performances then in use, which were chiefly of the nature of holy mysteries, were represented in the cathedrals. From the remains still existing, however, there would seem to have been large open-aired theaters at an early age in this country. Of these Piran Round in Cornwall is the best example. It is circular, with raised platforms all round for spectators, after the manner of the Greek theaters. With the revival of classical literature in the 16th c., the classical drama was also reproduced, and naturally along with it the classical form of theater. The first specimens of what may be called modern theaters (although founded on the old Greek model, according to Vitruvius's description) were the Teatro Olimpico, erected by Palladio in Vicenza; a similar one in Venice, also by Palladio; and another in Vicenza, by Serlio. In Italy and Spain, open court-yards, with galleries round them, were at first the scenes of dramatic performances. In France and England, where the climate did not so readily admit of open-air representations, the first plays performed were exhibited in tennis or racket courts, in which there were usually galleries at one end; and as this accommodation was found too limited, these were afterward carried along the sides also. But dramatic literature soon became so important that buildings had to be designed for the express purpose of its representation. Accordingly, in Paris, the theater of the hôtel de Bourgogne was erected in the beginning of 17th century. It was rebuilt 1645, with tiers of boxes on a square plan. In 1639, the theater of the Palais Royal was erected by Richelieu, and was long considered the best model. The present circular plan of the galleries, with pit sloping backward, seems to have been first introduced in Venice in 1629; and the horse-shoe form of the boxes was first carried out by Fontana in the Tordinoni theater, at Rome, in 1675. The modern form of the auditorium was thus invented, and gradually improved and perfected, till in about a century similar theaters were erected all over Europe; the Scala theater at Milan, the largest in Italy, and the great theater at Bordeaux, being built, the former in 1774, and the latter in 1777. The plan of the Scala theater at Milan shows the general disposition of all the parts of the modern theater on the largest scale. Modern theaters are all very similar in their general distribution. They are divided into two distinct departments—viz., the auditorium or audience department, and the stage or scenic department. In the former, the seats are invariably arranged on a sloping ground-floor or "pit;" and on several tiers or galleries, extending in a semicircular or

horse shoe form round the house. On the ground-floor, the front rows of seats are generally set apart as "dress stalls," and the back part only is then called the "pit." In opera-houses, the stalls generally occupy the greater portion of the space, and the "pit" is reduced to a minimum. In dramatic theaters, the tiers of galleries have the floors arranged in stages, rising above one another in such a manner as to enable the spectators all to see over those before them to the front of the stage. In theaters for operatic representation, the galleries have the floors laid level, and are divided all round into private boxes. The top tier is, however, sometimes left partially open, and has the seats on stages. In the larger opera houses, there are usually retiring-rooms connected with each of the private boxes. There is also a "crush-room," or large saloon, in which the audience may promenade between the acts. In all French theaters and opera-houses, these saloons, or *foyers*, are very large, and elegantly fitted up. They are almost always over the entrance-hall. In some of the modern French theaters, there are two foyers, one over the other, for the different classes who occupy the dress circle and the upper galleries. The question has often been raised as to the best form for a theater, both for hearing and seeing. It is a most difficult question to decide theoretically as regards hearing, but it is quite clear that the old semicircular plan of the Greeks is as nearly as possible the best for seeing, as it places the seats all round at an equal distance from the center of the proscenium; and therefore we find, where seeing well is all-important, as, for instance, in a *lecture theater*, this old form is usually adopted. In an oblong house, on the other hand, the seat at the center of the galleries are much further removed than those at the sides from the center of the stage, and are thus at a disadvantage as regards hearing; while the side boxes are badly placed for commanding a view of the stage. The entrances and staircases of theaters are not generally so well arranged or so spacious as they should be. In French theaters, this is especially the case. In these, there is often only one narrow wooden stair on each side of the house, leading to all the galleries. Recent accidents by fire, and the risk the audience runs in case of want of proper exits, have drawn attention to this subject, and the legislature will probably determine that there must be a separate, wide, and easy stair to each gallery—as, indeed, there usually now is in theaters recently built in this country. For large galleries, these stairs should be at least six feet wide; and a strong iron hand-rail down each side of the stair would be found useful in case of a panic, to prevent a fatal crush. Besides the main passages for the use of the public, there ought to be private passages and doors leading to every part of the house, so that the manager may pass with ease to any point in the audience where his presence may be required.

The orchestra occupies the space immediately in front of the proscenium, and this space is arranged so as to be capable of being enlarged or contracted as occasion may require. The proscenium is a small portion of the stage which projects a few feet in front of the curtain, so as to enable the actors to stand well forward, that they may be distinctly heard by the audience. The part of the house on either side of the proscenium is that on which there is usually the greatest amount of ornament. The sides and ceiling of the proscenium form, as it were, the frame through which the picture represented on the stage is seen; and as on it every eye must rest, it is made more ornate than the rest of the auditorium. The ceiling, presenting as it does a large broad surface, and being well seen from many parts of the house, is also a place well adapted for ornament, and is generally made as handsome as possible. The same remark applies to the fronts of the dress circle and galleries. The stage extends backward from the proscenium, and ought to be of considerable depth, so as to admit of the scenic effects, dissolving scenes, etc., now so much run upon. The great length of the stage from front to back is one of the most striking differences between the modern and the ancient theater, and arises entirely from the introduction and development of movable scenery—an invention of the architect Baldassare Peruzzi, and first used in Rome before Leo X., in 1508. The floor of the stage is not laid level like the floor of a room, but is sloped upward from front to back, so as to elevate the performers and scenes at the back, and render them more easily seen. The inclination of the stage is generally about half an inch to every foot. The stage department of a theater not only requires to be very long, but also very lofty above, and deep below the stage, so as to allow the large frames on which the scenes are stretched to be raised or lowered in one piece. The stage itself is a most complicated piece of mechanism, a considerable part of it being made movable either in the form of *traps*, for raising or lowering actors, furniture, etc., or in long pieces, which slide off to each side from the center, to allow the scenes to rise or descend. There are also *bridges*, or platforms constructed for raising and lowering through similar openings, some of them the full width of the stage. The traps and bridges are almost all worked by means of balance-weights, and the slides by ropes and windlasses. Besides the large *frames* above described as containing pictures occupying the full opening of the stage, there are other scenes which are pushed from the sides to the center, each being only one-half the width of the opening. These are called *flats*, and usually slide in grooves above and below. The grooves are arranged in clusters at intervals, having clear spaces between, called the *entrances*, through which the actors pass on and off the stage. But in modern French theaters and in the opera-houses—such, for instance, as Covent Garden theater—these grooves are regarded as an incumbrance to the stage, and are entirely done away with. Their place is occupied by narrow openings or slits in the stage, below which are

blocks running on wheels, and containing sockets, into which poles are dropped from above, and to these the flats are attached. Another advantage of this system is, that the gas-wings and ladders may be made movable, and slip backward and forward in the same manner as the flats. When occasion requires, the whole stage can thus be entirely cleared. According to the old plan of fixed grooves, only the center of the stage can ever be cleared without unscrewing all the grooves, and the gas-wings must always remain in the same relative position. Besides the flats, there are also smaller scenes which move in the grooves. These are called *wings*, and are used to screen the entrance. Corresponding to the wings are similar narrow scenes dropped from above: these are called *borders*, and are used to hide the gas-battens. These and the scenes which are drawn up, the gas-battens, etc., are all worked by means of ropes from the *flies*, or galleries running along the sides of the stage at a high level. The ropes from these passing up into the barrel-loft (a space in the roof filled with large drums and barrels on which the ropes are coiled) and down again to the flies, form a complication which seems to the uninitiated observer an inextricable mass of confusion. While such is the usual arrangement connected with movable scenery, it is to be noted that latterly a very great change has been introduced into the higher class of theaters. This change consists in the dismissal of wings or sliding side portions of scenes with intervening gaps, and substituting for them large pieces of scenery resembling the sides and further end of a room—an arrangement every way more natural. In cases of this improved kind, the actors enter on the stage and depart by doors. In connection with the stage, it is usual to have a large space set apart for continuing scenery, called the *scene-dock*. This is frequently placed at the back of the stage, and may, on occasion, be cleared out, to give extra depth to the scene. There are also numerous apartments required in connection with the stage for the working of the theater—such as manager's room; dressing-rooms for the actors and actresses; the "green-room," in which they assemble when dressed, and wait till they are called; "star rooms," or dressing-rooms for the stars; the wardrobe, in which the costumes are kept; furniture stores, scene stores; "property"-makers room; and workshops for the carpenter, gas-man, etc. There must also be a good painting-room, which must necessarily be a large apartment, from the size of the pictures which have to be painted—each being the full size of the opening of the stage. The canvas for these scenes is stretched on frames, which move up and down by means of a winch with balance-weights; and thus the painter stands comfortably on the floor, and moves his picture up or down, so as to get at any part he wishes. An interesting point on the stage is the prompt corner, from which the prompter has command of all the lights of the house, and bells to warn every man of his duty at the proper moment. He has a large brass plate, in which a number of handles are fixed, with an index to each, marking the high, low, etc., of the lights; and as each system of lights has a separate main pipe from the prompt corner, each can be managed independently. The side of the house on which the prompter is seated is called the "prompt side," and the other side is called the "O. P." or *opposite* side.

The house, or auditorium department, is generally lighted by means of a large luster or sun-light in the center of the ceiling, and much of the effect of the building depends on how this is managed. There are also usually smaller lights round one tier of the boxes at least. The proscenium is lighted by a large luster on each side, and by the foot-lights, which run along the whole of the front of the stage. These are sometimes provided with glasses of different colors, called *mediums*, which are used for throwing a red, green, or white light on the stage, as may be required. The stage is lighted by rows of gas-burners up each side and across the top at every entrance. The side-lights are called *gas-wings*, or *ladders*; and the top ones, *gas-battens*. Each of these has a main from the prompt corner. They can be pushed in and out, or up and down, like the scenery. There is also provision at each entrance for fixing flexible hose and temporary lights, so as to produce a bright effect wherever required. The mediums for producing colored light in this case are blinds of colored cloth. Another means of producing brilliant effects of light is the lime-light, by which, together with lenses of colored glass, bright lights of any color can be thrown on the stage or scenery when required.

Theaters are usually either very cold or insufferably hot. This arises from want of proper means of heating, and insufficient ventilation. The center luster is the great cause of ventilation, the draught caused by its heat drawing off the foul air at the ceiling. The suction caused by this withdrawal of air is naturally supplied from the great body of air in the stage. The stage ought, therefore, to be moderately heated by means of hot-water pipes or otherwise, so as to prevent cold draughts. The passages and lobbies round the house should also be heated in the same way, so that any air drawn in to the house may be properly tempered. An attempt has been made in Paris, of late years, to obviate the great heat and draught caused by the center luster, by doing away with the luster, and making the ceiling partly of glass, with powerful lights and reflectors behind the glass in the roof. This mode of lighting is, however, of rather a subdued character for a theater, although very appropriate to such chambers as the house of commons, where it acts admirably. In Paris they have also tried to supply fresh air from the gardens outside by means of a large tube, from which numerous small tubes branch and distribute the fresh air all round the theater from the fronts of the boxes, round the proscenium, etc. The idea is an excellent one, and is said to answer well practically.

There is a novel and agreeable class of theaters now in use in Germany, but of which we have as yet no specimens in this country. It consists of a double auditory, one at each end of the stage. One of these auditories is arranged and lighted in the usual manner, and is called the winter theater. The other auditory is called the summer theater, and is so arranged that performances may be represented in daylight during the summer season. It is lighted by large windows in the outer wall, which corresponds in form to the interior curves of the galleries, and also by windows in the roof. The entrances are by means of staircases at each side, near the proscenium, and by wide corridors and balconies round the curve of the exterior wall. One of the most effective of these summer-theaters is the Victoria in Berlin, by Zitz.

The art of *dramatic representation* has undergone great changes. In ancient Greece, partly from the character of the subjects selected, and partly from the origin of the drama itself, costume and acting were conventional, artificial, and stereotyped. On this point, we quote the words of Witzschel, who has written a handbook for students on the Athenian stage. (Eng. transl. by Paul; ed. by T. K. Arnold, Lond. 1850): "There can be no doubt," says he, "that the somewhat fantastic costume which was handed down without any change from one generation of actors to another was closely connected with the religious character of their tragic performances. The peculiar fashion and brilliant colors of the tragic wardrobe belonged rather to the Dionysian solemnities than to the stage. That Æschylus, by whom the greater part of it was invented, kept steadily in view the original intention of tragedy is evident from the notices which we find in ancient writers of his theatrical dresses having been worn in other religious ceremonies and processions. It is only reasonable to suppose that he would have given to the tragic stage a wardrobe of a very different description had he not been influenced by the conviction, that theatrical performances were in some sort a religious ceremonial. Another proof of the feeling entertained on this subject may be found in the ridicule with which Aristophanes overwhelms Euripides for introducing his heroes, not only in pitiable situations but in dirty, ragged, and beggarly weeds, to the great disgust of all true-hearted Athenians, and the utter annihilation of tragic ideality. In the *Acharnenses*, the whole of the tragic poet's squalid wardrobe is held up to public derision.

"The tragic costume for male characters of the highest rank consisted of an embroidered tunic with sleeves, which, in the older personages reached to the feet (*chiton poderes*), and in the younger to the knees. Over this was thrown a green pall, or long mantle (Gr. *surma*, Lat. *palla*), which also reached to the feet, and was richly ornamented with a purple and gold border. Persons of high but not royal rank wore a shorter red mantle, embroidered with gold, which was partially covered by a richly-embroidered, high-fitting scarf. Soothsayers wore over the tunic a kind of a network, composed of woolen threads. A sort of waistcoat (*kolpōma*) was also worn over the tunic. This was the costume of powerful and warlike sovereigns, such as Atreus, Agamemnon, etc. Dionysus (Bacchus) appeared in a purple tunic, which hung negligently from an embroidered shoulder-knot, and a thin, transparent, saffron-colored upper robe, with a thyrsus in his hand. Even Hercules himself was not the athletic hero of the old mythology, with a lion's skin thrown loosely round his muscular limbs, but a solemn, theatrical personage, enveloped in a long mantle. The costume of a queen was a flowing purple robe, with a white scarf; and for mourning, a black robe, and blue or dark yellow shawl. Persons in distress, especially exiles, wore dirty-white, dark-gray, dingy-yellow, or bluish garments. . . . To increase their height, the tragic performers wore the citharus, a sort of buskin, with high soles and still higher heels, which compelled them to walk with a measured and sounding tread; and a top-knot of hair, or toupet (Gr. *onykos*), suitable to the age and condition of the character represented. A corresponding breadth of figure was produced by means of padding and by a sort of glove. Thus equipped, the tragic hero seemed a giant as compared with ordinary mortals. Lastly, they had the mask, a part of the ancient theatrical costume which seems to us so strange and unnatural. For its meaning and origin we must go back to the Dionysian festival, at which the excited crowd were wont, in honor of the jolly god, to smear their faces with lees of wine; and at a later period, when dramatic interludes were attempted, with vermilion, or to cover their cheeks with rude masks of bark. In the course of time these primitive inventions were discarded, and their places supplied by linen masks, characteristically painted. For the sake of retaining this uncouth but distinctive appendage of the Dionysian festival, the Greeks were content to forego the delicate expression of feeling and eloquent play of features which are indispensable to a modern actor; but on the other hand, when we remember the enormous size of their theaters, which scarcely permitted the assembled thousands to hear what was said by the actors, still less to distinguish their features, we are forced to acknowledge that the practice of wearing masks was rather an advantage than an inconvenience." The above description is, in the main, applicable to the Roman as well as the Greek theaters. The only additional point which it is necessary to notice is that, among the ancients, the acting of plays was not (as it is now) a regular and daily, but only an occasional affair, at festival seasons and the like. With the fall of the western empire, the disappearance of classic paganism and classic tastes, and the triumph of the Christianised barbarians of the n. and e., theatrical performances ceased. But the liking for such things is not artificial; it is natural and irrepressible; and gradually, as the ancient culture resumed

something of its former sway, efforts were made, not indeed, to re-enact the majestic tragedy of Greece (for its language was scarcely known), or the pungent comedy of Rome, but to throw into dramatic form the "mysteries," "miracles," and "moralities," of the Christian religion. The rudeness of these mediæval plays may perhaps suggest to us what Greek performances were before the days of Thespis. In fact, they were introduced as a means of edifying, as much as of amusing, the ignorant laity, were customarily the works of monks, and were performed on festive occasions in the churches. It does not, however, appear that they were accompanied by any *scenic* representations. A raised wooden stage like that which forms the front of a traveling show, was all that the untutored taste of the times demanded. Nor are we to suppose for a moment that the slightest attention was paid to propriety of costume or speech. The personages rather than the actions, the ceremony rather than the dialogue, the moral rather than the matter, were the things looked to, and hence no subtle or artistic representation of life and character was possible. The development of the modern drama (q.v.) ultimately restored the art of the actor to its ancient dignity and importance; but it was long before those changes took place that gave theatrical performances their modern character. Good acting—that is to say, skillful impersonation of character and varied elocution—became quite common in England after the restoration, and was not unknown before it; but appropriate costume and scenery were scarcely thought of until the time of Talma (q.v.), toward the close of last century. Since then the best theaters have displayed a most creditable desire to reproduce, with something like verisimilitude, the outward "form and pressure," the garb, deportment, and air of the age represented.

The employment of female actors is of French origin, and dates from the first half of the 17th c.; but they were not permitted (without molestation) to tread the English stage till 1661. Before this innovation, female parts were performed by youths; and though it ill consorts with *our* ideas of adequate representation to conceive the parts of Desdemona, Ophelia, Cordelia, etc., executed by those of another sex, it would appear that several actors obtained a wonderful success in this line.

The title of "his majesty's servants," which English actors once bore, originated in the fact that some of them were really members of the royal household. The king and particular nobles kept troops of actors for their own pleasure, whom they sometimes permitted to go about the country and perform. The first prince we read of that gave his "servants" such permission, was Richard, duke of Gloucester (afterward Richard III.). In queen Elizabeth's time (1571), the earl of Leicester's "servants" were licensed to open the first *public* theater in England, and it is owing to the circumstance of actors having originally formed part of the household of the king that a license from the lord chamberlain is still necessary to the opening of a theater.—For an anecdotal and amusing history of the English stage see *Their Majesties' Servants*, by Dr. Doran (1865); see also Dutton Cook's *Book of the Play* (1876).

THEATERS, LAWS AS TO. In Great Britain all theaters must be licensed, either by virtue of letters-patent from her majesty, or by license from the lord chamberlain for the time being, or from justices of the peace. The lord chamberlain grants licenses to all theaters (not being patent theaters) within the English metropolis, and within the places where her majesty occasionally resides, except New Windsor and Brighton. For every license of the lord chamberlain, a fee not exceeding 10s. per month is charged. In other parts of Great Britain, the justices of the peace of the county, city, or borough must be applied to for a license; and after the usual notice, they hold a special session, for the purpose of granting licenses to theaters, the fee payable being a sum not exceeding 5s. per month. It is only to the actual and responsible manager of the theater that a license can be granted, and his name and place of abode must be printed on every play-bill. The manager must find sureties to observe the rules issued by the lord chamberlain and justices, which rules relate to the days and hours of keeping open, and the insuring of order and decency. A penalty of £10 is imposed, by statute 6 and 7 Vict. c. 68, on any actor or manager concerned in unlicensed places.

A copy of every new play, epilogue, or prologue, or alteration of the same, intended to be produced at any theater in Great Britain, must be sent to the lord chamberlain, by the manager, seven days before such production; and for examination of such plays and alterations of plays, he may charge fees not exceeding ten guineas, according to a scale fixed by him. He may forbid the acting of any play, whenever he considers it to be fitting to the preservation of good manners, decorum, or the public peace, to do so. To act a play not allowed or disallowed, subjects each actor and manager to a penalty of £50. It has been decided by the courts, that a booth used as a temporary or portable theater requires a license, and that any dialogue or dramatic performance by two persons is a stage-play, and therefore subject to the license. Of late, the policy of placing the theaters so entirely under the control of the lord chamberlain and justices has been disputed, especially as the increasing practice of introducing theatrical performances at public supper-rooms has led to some vexatious prosecutions at the instance of the licensees of regular theaters.

THEATINES, one of the more modern religious brotherhoods of the Roman Catholic church, which played a very important part in the well-known internal movement for

reformation which took place in central and southern Italy toward the middle of the 16th c., and which Ranke has described in his *History of the Popes*. The founders of this association were a party of friends: Cajetan di Thiene; John Peter Caraffa, at that time bishop of *Theate* (from which the congregation took the name *Theatine*); Paul Consiglieri; and Bonifazio di Colle. Cajetan and Caraffa, in concert with the two other friends named above, having resigned all their preferments, obtained a brief of Clement, dated June 25, 1524, formally constituting the new brotherhood, with the three usual vows, and with the privilege of electing their superior, who was to hold office for three years. One peculiarity of their vow of poverty deserves special notice: they were forbidden to possess property, and were to subsist entirely upon the alms of the faithful; and yet they were strictly forbidden to beg, or in any way to solicit charitable contributions. Their first convent was opened in Rome, and F. Caraffa was chosen as the first superior. He was succeeded in 1527 by Cajetan, and the congregation began to extend to the provinces. After a time, however, it was thought advisable to unite it with the somewhat analogous order of the Somaschans; but this union was not of long continuance; Caraffa, who was elected pope, under the name of Paul IV., having restored the original constitution in 1555. By degrees, the Theatines extended themselves, first over Italy, and afterward into Spain, Poland, and Germany, especially Bavaria. They did not find an entrance into France till the following c., when a house was founded in Paris under cardinal Mazarin in 1644. To their activity, devotedness, and zeal, Ranke ascribes much of the success of that remarkable reaction against Protestantism which took place in the latter half of the 16th century. In later times, however, they do not appear to have played any notable part. Their most remarkable member in modern times has been the celebrated Sicilian, Father Ventura, author of the well-known work *Bellezze della Fede*, and familiar to Englishmen by the part which he took in the Italian revolution of 1849. At present, the Theatine order is confined to Italy and Sicily.

THEINER, AUGUSTIN, 1804-74; b. Breslau; studied at Breslau and Halle; assisted his brother Johann Anton in a work on the history of celibacy; wrote an essay on the papal decretals which found great favor; visited Rome, 1831, became a member of the oratory of St. Philip Neri, fully identified himself with the ultramontane party, was consulter of the holy office. In 1848 he published a work opposing the election of bishops and priests by laymen, and maintaining the temporal sovereignty of the popes; was appointed in 1851 keeper of the secret archives of the Vatican, and published compilations illustrating the ecclesiastical history of the different Christian nations. His greatest work was the continuation of the *Annales Ecclesiastici* of Baronius in 1856. Having in 1869 corresponded with Dr. Döllinger and prof. Friedrich, and advocated the Old Catholic doctrine and position, he was debarred access to the archives, but his salary was continued, and he remained in the Vatican.

THEBAINE. See ORPUM

THEBES, the name of a celebrated Egyptian city, called by the Egyptians Taape, or Taouab; by the Hebrews, No-Amen; by the Greeks, Thebæ; and at a later period, Diospolis Magna. It lies in the broadest section of the valley of the Nile, in about lat. 26° n., and was formerly the capital of Southern or Upper Egypt. Its ruins, the most extensive in that country, comprise nine townships, the most remarkable of which are Medinat Habu, Gournah, Karnak, and Luxor. Its local and eponymous god was Amen-Ra, or Jupiter Ammon; and its foundation traditionally dated from the time of Menes, the founder of the monarchy, although no remains of so early a date have been discovered on the site. Recently, however, excavations have brought to light constructions of the 11th dynasty, who appear to have founded the original temple of the god. The Nile flows through the midst of the ancient city, and divides into four principal quarters: Karnak and Luxor, which lie on the e. bank, and Gournah and Medinat Habu, on the w. bank of the river. The most flourishing period of the city was under the 18th, 19th, and 20th dynasties, or from about 1500 to 1000 B.C., when it had supplanted Memphis, the ancient capital of the Pharaohs. The more central situation of this city probably caused it to rise into importance, for it was secure against the northern enemies of Egypt; hence, under these Diospolitan dynasties, the worship of Amen-Ra arose in all its splendor; magnificent palaces and temples were built in its different quarters, to which additions were made by later monarchs, and even by the Ptolemies and Romans till the time of the Antonines, in the 2d c. A.D. Here, too, were the cemeteries of the Theban monarchs and the officers of their courts, colleges of priests, and the seat of royal government. It was enriched by the spoils of Asia and the tributes of Ethiopia, and its fame and reputation had reached the early Greeks, Homer describing it by the epithet of Hekatompylos, or City of a Hundred Gates, in allusion to its propylaea, for Thebes was never a fortified city. In the plenitude of its power it sent forth an army of 20,000 war-chariots; but the Bubastite and Tanite dynasties removed the capital again to Sais and Memphis, and Thebes declined in importance, although retaining much of its ancient grandeur. At the Persian conquest, Cambyses obtained a spoil of nearly £2,000,000 from the city, destroyed many of its noblest monuments, and injured its political pre-eminence. The foundation of Alexandria by Alexander the great, and other causes, still further injured the city; and although some repairs were made under the subsequent monarchs, its grandeur had departed. At the time of Strabo,

Thebes was only a cluster of small villages. When that geographer visited the city its extent was about $9\frac{1}{2}$ m. in length (according to Diodorus), its circuit was about 16 miles. Its temples, tombs, and ruins were visited by the Roman travelers; and Germanicus and Hadrian inspected the sculptures of the temples. At a later period, a considerable Christian population existed under the empire; but the inhabitants fled at the Arab invasion to Esneh; and Thebes is now inhabited only by a few Arab families of Fellahéen, who obtain a precarious livelihood by guiding travelers over the ruins, or rifling the tombs for antiquities. At Gournah, is to be seen the Memnonion, built by Ramesses II.; with a colossus of that monarch, weighing $887\frac{1}{2}$ tons, the largest statue in Egypt, broken. This is supposed to be the palace of Osymandyas, described by Hecataeus, and is of considerable extent. In this quarter are two palace-temples of Amenophis III., and the vocal Memnon, or celebrated colossus of that monarch, supposed by the ancients to emit a sound at sunrise. At Medinat Habu is a pile of buildings, commenced by Thothmes I., of the 18th dynasty, with courts and propylæa, built by Ramesses III. or Rhampsinitus, and sculptures representing his victories over the Philistines, the life in his harem, the riches of his treasury, and a calendar with inscriptions dated in the twelfth year of his reign. Here, 8,000 ft. to the n.w., are the cemeteries of sacred apes; and 3,000 ft. beyond, the valley of the tombs of the queens, consisting of 17 *syringes*, or sepulchers, supposed to be the tombs of the Pallacides of Amen, mentioned by Diodorus and Strabo. Near them are the Biban-el-Meluk, or tombs of the monarchs of the 19th and 20th dynasties, 16 in number, the most interesting of which are that of Sethos I., called Belzoni's, after its discoverer, and those of Ramesses III., and Siptah. At Gournah itself are the tombs of functionaries and others, and this latter site has enriched the museums of Europe with antiquities of various kinds. The palaces of the Luxor quarter were founded by Amenopais III. From hence was removed the obelisk of the Place de la Concorde in Paris. Still more magnificent than any of these is the temple of Karnak, the sanctuary of which, built by Osertesen I. of the 12th dynasty, was added to by the monarchs of the 18th dynasty. The most remarkable part of this wonderful mass of courts, propylæa, and obelisks, is the great hall, 170 ft. by 329 ft., built by Sethos I. and Ramesses II., having a central avenue of 12 massive columns, 60 ft. high, 12 ft. in diameter; and 122 other columns, 49 ft. 9 in. high, 27 ft. 6 in. in circumference; and 2 obelisks, 92 ft. high, and 8 ft. square. In this temple is also the so-called portico of the Bubastites, built by Shishak I., recording his expedition against Jerusalem, 971 B.C. The Ptolemies also restored this building.—Diodorus, i. 45; Strabo, xvi. p. 816; Wilkinson, *Topography of Thebes* (8vo. Lond. 1835); Champollion, *L'Égypte*, i. p. 199, and foll.; *Lettres*, pp. 63-73; Belzoni, p. 58.

THEBES, the principal city of Beotia, in ancient Greece, was situated in the southern part of the country, on the slopes of Mount Teumessus, and between two streams, the Dirce and the Ismenus. According to the prevalent tradition, Thebes was founded by a colony of Phenicians under Cadmus (q.v.), after whom the city was called Cadmeia—a name subsequently restricted to the citadel; but passing over the long series of picturesque and tragic myths that have given it its pre-historic fame (in which the central figure is Œdipus), we first catch a quasi-authentic glimpse of Theban history in the 8th c. B.C., when one Philolaus, a Corinthian, settled in the place, and drew up a code of laws for the inhabitants. It is not till near the end of the 6th c. B.C., however, that we reach a purely historical period—the earliest well-attested event being the dispute between Thebes and another Beotian city, Platææ, which involved the former city in an unsuccessful war with Athens. Henceforth, the relations of Thebes and Athens were, except for brief intervals, marked by bitter enmity. During the Persian war Thebes shamefully sided with the Asiatic invader, and, in consequence, lost much of her power and prestige. Athens proposed to deprive her of her supremacy over the Beotian confederacy; but Sparta, always jealous, even to spitefulness, of her Attic rival, interfered, and positively forced the other Beotian cities to acknowledge anew their unworthy mistress. When the Peloponnesian war broke out, Thebes took part with Sparta, and at its close, was eager for the destruction of Athens; but soon after it became jealous of the overgrown power of its ally, and gave a friendly welcome and shelter to those Athenians whom the oppression of the Thirty Tyrants (q.v.) compelled to abandon their city. It was from Thebes that Thrasybulus and his co-patriots started on their famous expedition for the deliverance of Athens, accompanied by a body of Theban citizens. A keen and bitter antagonism now sprung up between Thebes and Sparta, which, after many vicissitudes, ended in a great military struggle (379-362 B.C.), in which the former city, under the heroic guidance of Epaminondas (q.v.), achieved a brilliant triumph, and for a time held the position of the foremost power in Greece. It was now the time for Athens to revive her ancient animosities; and for a while they had free play. At length the eloquence of Demosthenes induced both states to unite in opposition to the encroachments of Philip of Macedon; but it was too late; and in 338 B.C. the battle of Chæroneia crushed the liberties of Greece. After Philip's death the Thebans made a fierce but unsuccessful effort to regain their freedom. Their city was taken by Alexander, who levelled it to the ground, and sold the entire population—men, women, and children—into slavery. For 20 years it remained an utter desolation; but in 315 B.C. it was rebuilt by Cassander, who gathered into it all the Thebans he could find in Greece. It was

again destroyed by the Romans, and did not recover till about the decline of the empire. During the 11th and 12th centuries it was the seat of a considerable population engaged in the manufacture of silk; but under the Turks it again declined, though it has still a modern representative, Thebes, or Thiva, with a pop. of 9,000. Scarcely a single relic of antiquity has survived the ravages of time.

THECLA, a virgin saint of the early church, whose existence may be considered historical, although all, or almost all, the details regarding her are legendary, being in great measure founded upon an apocryphal book, now lost, entitled *The Periods (circuits) of Paul and Thecla*, the unhistorical character of which is declared by Tertullian (*De Bapt.* ii. 17), and by St. Jerome in his catalogue of ecclesiastical writers. According to the legend, Thecla was a member of a noble family of Iconium in Lycaonia, where she was converted by the preaching of St. Paul, and having devoted herself to a life of virginity, suffered a series of persecutions from her intended bridegroom, as well as from her parents. As to the manner of her death, nothing is certain. She is styled in the Greek martyrologies the *proto-martyress*, as Stephen is the *proto-martyr*; while in the Roman breviary she is said to have died at the age of 90 in Seleucia, where her tomb was anciently pointed out. The *Acts of Paul and Thecla* was among the books stigmatized as "apocryphal" by pope Gelasius; but it is now lost.

THEFT. See LARCENY.

THEINE. See CAFFEINE and TEA.

THEISM, the doctrine concerning God, differing from pantheism by the relation which it affirms between God and the world of things; and from deism by the relation which it acknowledges between God and man. The pantheist asserts that God and the world are one; while the theist believes that a personal God, the creator of the world, is independent of it. The deist admits that God is the creator of the world, but denies that he has given a written revelation to man. Consequently, if man could exclude from his mind all the light which comes from revelation, his way would be dark indeed. But as the divine light shines around him, whether or not he acknowledge the source of it, his deism may become almost theism.

THEISS, an important affluent of the Danube, and the chief river of Hungary, rises by two streams, the Black Theiss and the White Theiss, in the Carpathian mountains, on the borders of Galicia. It flows first s. through a mountain-pass; but after receiving the Viso from the s.e., it changes its course to n.w. and s.w., flowing past Tokay to Szolnok, where it curves toward the s.; and after running parallel to the Danube for upward of 300 m., it joins that river about 5 m. below the town of Titel. The principal towns upon its banks are Szigeth, Tokay, Szolnok, Csongrad, and Szegedin. About one half of this last town was destroyed by an inundation of the Theiss in the spring of 1879. Its chief affluents are—the Vörsova, Bodrog, and Hernad, the Szamos, Körös, Maros, and Bego, the most of which are navigable. The Theiss is navigable at Szegeth for small vessels, at Namény for steamers, and at Szolnok for large vessels. At Szöllös it enters upon the plain, and below this point its fall is trifling, its course sluggish and very winding, and its banks low and marshy. At Tokay it is 300 ft. broad; at Szegedin, 400 ft.; and at Titel, 740 feet. Its length, in direct line from source to mouth, is 280 m.; the entire length, including windings, is 828 miles.

THELLUSSON ACT is an act of parliament, 39 and 40 Geo. III. c. 98, passed for the purpose of checking the disposition of testators to accumulate the income of their estates until it should form a large fortune. The late Mr. Thellusson had, by his will, directed his personal property to be invested in land, and the rents and profits of the land to be so purchased, and of his other real estate, to be accumulated during the lives of all his descendants who should be living at the time of his death, or born in a certain time thereafter; and then he limited the accumulated property in favor of certain of his descendants who might be then living at that distant time. The property was said to have consisted of landed estates worth £4,000 a year, besides personalty of about half a million; and it was estimated that the accumulated fund would amount to above 19 millions. The testator's object was to create enormous wealth for the purpose of founding three families to spring from his three sons. For three quarters of a century the questions arising out of this will have been discussed in various forms; but the legislature, soon after the testator's death, took the earliest opportunity of preventing in future testators accumulating the income in this way for more than 21 years, and the above act was passed for that purpose. In the courts the first attempt to upset the will of Mr. Thellusson was to make out that it was too uncertain to be carried into execution—next, that the accumulation was illegal—next, whether males claiming through females would be entitled to a share: all of which attempts to upset the will failed. Ultimately, however, the fund proved not to be so large as was anticipated, and was distributed among a greater number of claimants. The eldest son was created baron Rendlesham in 1806. The litigation ended by a decree of the house of lords in 1858. The Thellusson act has been extended to Scotland.

THEMIS (Gr. "what is established by old law"), in Greek mythology, was the daughter of Uranus and Gæ (heaven and earth), the wife of Zeus, and, by him, mother of the Horæ (hours) and Mœræ (fates), as also of Eunomia (equity), Dikē (justice), and Eirēnē

(peace). She was regarded as the personification of order and justice, or of whatever is established by "use and wont;" and as such was charged by Zeus to convoke the gods, and preside over them when assembled, being likewise represented as reigning in the assemblies of men. In modern art Themis is represented as having her eyes bandaged, and at the same time holding a pair of evenly-balanced scales in one hand, with a sword in the other.

THEMISTOCLES, the great Athenian general and statesman, was the son of an obscure citizen of Athens, and was born about 514 B.C. He was actuated by excessive ambition from a very early period, and began his public career by setting himself in opposition to the principal men of the state, and chiefly Aristides, "the just." It is uncertain whether he was at Marathon, but there is no doubt that the laurels gained there by Miltiades fired Themistocles's ambition. From the time (483) that he got his inconveniently upright rival, Aristides (q.v.), ostracised, he was regarded as the political leader in Athens, being made archon eponymus in 481. In order to recover for Athens the naval supremacy in Greece, and that she might be prepared to meet the expected Persian invasion, he persuaded the Athenians to devote the proceeds arising from the silver mines at Laurium to the construction of a fleet, sagaciously foreseeing that his country's only chance of overcoming her enemy was by sea. In the battles of Artemisium and Salamis (480), disastrous for the Persians, Themistocles, commander of the Athenian fleet, the largest in Greece, to avoid dissensions, was content to serve under Eurybiades the Spartan. On both these occasions it was only by the greatest tact, combined with threats and a judicious outlay of the bribes which he himself had received in profusion, that Themistocles could induce the other commanders to come to an engagement with the Persians. On the night previous to Salamis he sent a faithful slave to tell Xerxes that, unless he came up next day, the Greek fleet would be scattered, and he would miss the chance of an engagement; thus securing either victory to the Greeks or the favor of Xerxes to himself in case of defeat. See SALAMIS. In several other ways did the wily Themistocles contrive to provide for himself a safe retreat at the Persian court in case of disaster. The victory at Salamis raised his reputation to the highest point. Not neglecting his own personal aggrandizement, he sailed round among the Grecian islands, and on various pretexts extorted enormous sums from the inhabitants. Shortly after the Persian invasion, his fellow-citizens began to see through him, and he was accused of bribery and extortion. In 471 he was ostracised and retired to Argos; and finally, to escape being tried for treason, in which he was implicated by the correspondence of Pausanias, he betook himself, in 465, to the court of Artaxerxes, king of Persia; but before he would see the king himself, got permission to wait a year, during which he made himself master of the language and usages of Persia. At the end of this time he managed to raise himself so highly in the king's favor that, after the Persian fashion, the town of Magnesia was appointed to supply him with bread, Lamp-sacus with wine, and Myus with other provisions. He lived securely at Magnesia until his death in 449. Some authorities assert that he poisoned himself. A monument was erected to Themistocles in the market-place of Magnesia, and it is said that his bones were secretly taken to Attica, and burned there. Undoubtedly Themistocles was a man of very great sagacity and determination, had a quick and keen perception of difficulties both present and future, which his ready invention, backed by promptness of action, enabled him to meet and overcome. On the other hand, he appears to have been possessed of no moral principles, his greatest ambition apparently having been to make himself, by fair means or foul, the greatest man in Greece.

THÉNARD, LOUIS JACQUES, Baron, 1777-1857; b. Nogent-sur-Seine; studied chemistry with Vauquelin in Paris; demonstrator of chemistry in the polytechnique school of Paris, 1797-1837, subsequently professor of chemistry in the college of France and in the university of Paris. The title of baron was given him in 1824; member of the academy, 1833; made peer of France in the same year. He resigned his chair in the university, 1840. With M. Gay-Lussac he published *Recherches Physico-chimiques*. In 1813 he began the publication of *Traité de Chimie Élémentaire, Théorique et Pratique*, translated into German and French. He has given more time and money toward developing the scientific institutions of France than any one since Cuvier.

THE NARD'S BLUE. See BLUE.

THEOBALD, LEWIS, was the son of an attorney at Sittingbourne in Kent, at which place he was b. toward the close of the 17th century. His father's business, for which he was educated, proved not much to his mind; and betaking himself to literature, he published, in 1714, a tragedy entitled *Electra*, which he followed up by a number of other dramas. As a poet, he had scant success, and is long since utterly forgotten; but as the favorite butt of Pope, he is immortalized in the *Dunciad* of that writer. Besides this unenviable distinction, "piddling Theobald," as Pope contemptuously termed him, is not without some fair claim to be honorably remembered as one of the most laborious and useful of the early editors and commentators on Shakespeare. In this capacity, dull as he undoubtedly was, he did good service to the poet, which has since been sufficiently recognized. The hatred of Pope he incurred by a pamphlet published in 1726, entitled *Shakespeare Restored, or Specimens of Blunders committed or unamended in Pope's Edition of this Poet*; and if he could not compete with his adversary in wit, he proved

himself a much more complete editor of Shakespeare by his edition in 7 vols. 8vo, published in 1733, which quite extinguished that of his rival. His knowledge of our earlier drama was extensive and minute; and to his judicious application of it, in elucidating the text of the great poet, we remain to this hour not a little indebted. He died in Sept., 1744.

THEOBROMINE ($C_{14}H_8N_4O_4$) is a crystallizable principle present in chocolate. It is extracted from the cacao-nuts (the seeds of *theobroma cacao*) in the same manner as caffeine or theine is extracted from the coffee, tea, etc., in which that substance occurs. It is less soluble in water than caffeine, but resembles that substance in forming crystallizable salts with some of the acids. By dissolving theobromine in a solution of ammonia, and adding nitrate of silver, a gelatinous precipitate is obtained, which, by boiling with a solution of ammonia, yields a crystalline mass of theobromide of silver ($C_{14}H_7AgN_4O_4$), in which 1 equivalent of hydrogen is replaced by 1 of silver. This compound, when treated with iodide of methyl, yields iodide of silver and caffeine, which latter may be extracted with alcohol. Hence we arrive at the remarkable conclusion, that caffeine ($C_8H_{10}N_4O_4$) must be regarded as methyl-theobromine $C_4H_7(C_2H_5)_2N_4O_4$.

THEOCRACY, literally, "government by God," is the name given to that constitution of a state in which the Almighty is regarded as the sole sovereign, and the laws of the realm as divine commands rather than human ordinances. Under such a view, the priesthood necessarily become the promulgators and interpreters of the "divine commands," and act as the officers of the invisible Ruler. The most famous example of a theocracy is that established by Moses among the Hebrews.

THEOCRITUS, the creator and most celebrated composer of bucolic poetry, was the son of Praxagoras and Philinna, and b. at Syracuse. The date of his birth is unknown, but the period of his greatest literary activity was probably 272 B.C. About the close of the reign of Ptolemy Soter, he visited Alexandria, where he received instruction, and made his first successful essays in poetry. He came to be patronized by Ptolemy Philadelphus, who assisted his father, Ptolemy Soter, in the government of Egypt; and in honor of his patron, he composed, about 285 B.C., his 14th, 15th, and 17th idyls. He further formed the acquaintance of the poet Aratus, to whom he addressed his 6th idyl. He subsequently revisited Syracuse, where he continued to reside under Hiero II. From his 16th idyl, it may be concluded that he was dissatisfied with the political state of Sicily, and also with the insufficient rewards which his poems received from Hiero; and that, in consequence, he fixed his attention, during his declining years, rather on the life of the country than of the court, and on those scenes of rural nature which form the chief subject of his poetical remains. The idyls of Theocritus are principally representations, dramatic and mimetic in their character, of the every-day life of the Sicilian peasantry. They have been successfully imitated by Virgil, and have given origin at least to that so-called pastoral literature of mediæval and modern times, which is, however, totally deficient in the simplicity, fidelity, and therefore poetry of the Syracusan author. Theocritus knows nothing of the imaginary shepherds of a fictitious Arcadia; his dramatic simplicity and truth are in wide contrast to the affected sentiment, the unnatural innocence, and the artificial simplicity of that unreal world. Comedy and pathos enter freely into his representations of rural Sicilian life, and his idyls retain the charms of freshness and nature even to the present day. They are 30 in number, though all of them are not strictly bucolic, or even genuine. They are written in a mixed dialect, in which the softened Doric prevails; and together with a few lines from a lost poem called *Berenice*, and 23 epigrams in the Greek anthology, make up his remains, of which the best editions are those of Meineke and Paley; and the best translation in English, that of Dr. M. J. Chapman.

THEODICY (Gr. *Theos*, God, and *diké*, justice; Lat. *Theodicea*, the judgment of God), a name given to the exposition of the theory of Divine Providence, with a view especially to the vindication of the attributes, and particularly of the sanctity and justice of God in establishing the present order of things, in which evil, moral as well as physical, so largely appears to prevail. The name is of modern origin, dating from the close of the 17th c., or the beginning of the 18th c.; but the theory itself, as well as the mysterious problem which it meant to resolve, is as old as philosophy itself. See **EVIL**. The first to consider the question in its integrity was the celebrated Leibnitz (q.v.). His work entitled *Essais de Theodicée sur la Bonté de Dieu, la Liberté de l'Homme, et l'Origine du Mal*, was published in 1710. It rose at once to the very highest point of popularity, and was translated into almost every European language. The leading principle of Leibnitz's vindication of God's goodness is the well-known optimistic theory which has been explained elsewhere (see **OPTIMISM**); but he had been followed by several writers in different countries—as Balguy, Werdermann, Kindervater, Creutzer, Benedict Kapp, and many others. Of these writers, it may be said in general, that they have followed the same method, and have addressed themselves to the same view—viz., the reconciliation with the goodness, the sanctity, and the justice of the one God, the existence of those manifold evils, physical or material, as well as moral, which appear in the present order of things. This view, it will be seen, is strictly limited to one single problem. But in the discussions of the new philosophic systems, and especially that of Hegel, which have arisen in Germany, new difficulties regarding the Christian idea of God have arisen out

of the rationalistic notions of existence in general. To meet those difficulties, a new theodicy has become necessary, and it has begun to occupy the attention of philosophers, especially in France. Two works in particular addressed to this view of the subject may be noticed; the first is M. Maret's *Christian Theodiceë, or Comparison of the Christian and the Rationalistic idea of God*, 1845; the second is that of the Jesuit philosopher, Père Gratry, who has devoted the first volume of his course of philosophy, *De la Connaissance de Dieu*, to this special subject. This work was published at Paris, 1853.

THEODOLITE (Gr. *theaô*, I see, *dolichos*, long), an instrument much employed in land-surveying for the measurement of angles horizontal and vertical is neither more nor less than an altitude and azimuth instrument, proportioned and constructed so as to be conveniently portable. Like all instruments in very general use, the variations in its construction are almost numberless; but its main characteristics continue unaltered in all forms. It consists essentially of two concentric circular plates of copper, brass, or other material (the upper plate, or *upper horizontal*, either being smaller, and let into the lower, or *lower horizontal*, or the rim of the lower raised round the outside of the upper), moving round a common axis, which, being double, admits of one plate moving independently of the other. Upon the upper horizontal rise two supports, bearing a cross bar, which is the axis of a *vertical circle* moving in a plane at right angles to the former. This latter circle either has a telescope fixed concentric with itself, or a semicircle is substituted for the circle, and the telescope is laid above, and parallel to its diameter. The circles, as their names denote, are employed in the measurement of horizontal and vertical angles. For these purposes the outer of the horizontal circles is graduated, and the inner carries the index-point and the verniers (q.v.); the vertical circle is also graduated, and the graduations are generally read off by an index-point and vernier firmly attached to the supports. The upper horizontal is furnished with two levels placed at right angles to each other, for purposes of adjustment, and has a compass-box let into it at its center. The stand consists of a circular plate supported on three legs, and connected with the lower horizontal by means of a ball-and-socket joint; the horizontal adjustment of the instrument being effected by means of three or four (the latter number is the better) upright screws placed at equal distances between the plates. The telescope is so fixed as to be reversible, and the adjustments are in great part similar to those of other telescopic instruments, but are too numerous and minute to be here detailed. Both horizontal plates being made, by means of the screws and levels, truly level, the telescope is pointed at one object, and the horizontal angles read off; it is then turned to another object, and the readings-off from the graduated circle again performed; and by the difference of the readings, the angular horizontal deviation is given; and when vertical angles are required, the readings are taken from the vertical circle in a similar manner.

THEODORA, Empress, 508-548; b. Cyprus; a dancer and courtesan at Constantinople, to whom Justinian was married in 525. He proclaimed her empress on his accession to the throne in 527, and she seems to have exerted considerable influence in public affairs. The legislation of Justinian for improvement of the stage was, no doubt, due to her. By that legislation any actor becoming a Christian could not be obliged to remain upon the stage if he had conscientious scruples against doing so.

THEODORE, King of Abyssinia, otherwise described as Negus, emperor or king of kings of Ethiopia, a prince whose extraordinary career has excited much interest since war was declared against him by the English government. At the time when the article ABYSSINIA first appeared in this work, the subject was not of much importance to English readers, and a few additional remarks were therefore necessary to explain the leading events in the life of Theodore. Abyssinia forms, it will be recollected, a table-land, which, although lying within the tropics, has, owing to its great elevation, a cool and equable climate. Its inhabitants, who have a Caucasian or European physiognomy, profess Christianity, acknowledge a bishop or abuna selected and consecrated by the Coptic patriarch of Alexandria, make use of a system of law based on the code of Justinian, and have otherwise preserved some share of the civilization of ancient Rome. The Abyssinian empire was at the height of its power in the 6th c., when it extended to the shores of the Red sea, and even included a part of southern Arabia. The Mohammedan conquests drove back the frontier to the limits of the table-land; and since the 7th c., the inhabitants have been engaged in a ceaseless warfare with negro tribes, and with the great Mohammedan powers. They have been surrounded on all sides by hostile races. The tradition of the great power of the Negus lingered in Europe throughout the middle ages; and although separated from the west, the Abyssinians continued to consider themselves one of the Christian and civilized communities. In the 15th c., when on the point of yielding to the invaders, they appealed to the Portuguese for assistance, and it was granted, on condition that they should abandon the rites of the Coptic church, and yield unqualified submission to the pope. The promise was given, and the invaders were driven back. The royal family received the Roman Catholic priests, and professed the tenets of the Latin church. They could not, however, induce the native clergy and the people to follow them; and their adoption of a foreign creed was the first step to the weakening of the royal power, which had been absolute for ages, and which rested on a firm basis of tradition and custom, particularly strong among a

people in the stage of progress attained by the Abyssinians. The royal family still represented are of great antiquity, and are devoutly believed by their subjects to have sprung from Menelek, a son of Solomon and the queen of Sheba. The Abyssinian church certainly dates from the 4th c., when the first bishop, or abuna, settled at Axum. The abuna is appointed and consecrated by the Coptic patriarch of Alexandria, whose supremacy he recognizes. The dissensions introduced by Catholicism in the 16th c. were followed by invasions of the Gallas on the s., and the Turks on the north. The bitterness of the struggle with the latter has been increased by the large contribution exacted by the Egyptian government on the consecration of an abuna, and represented to be a tribute or acknowledgment of suzerainty. A frantic jealousy of the Turks among all ranks of Abyssinians is now one of the most prominent facts in Abyssinian politics. The decay of the royal power in the 16th c. led to a phenomenon frequently repeated both in India and Europe. Just as the Merovingian kings of France became mere titular monarchs, the emperors of Ethiopia became "puppet kings." They were chosen from the royal stock by the great feudatories, but retained the mere insignia of royalty. When the great chiefs could not agree in the selection of a monarch, any one who found himself strong enough would march upon the capital, and place upon the throne one of the royal stock, and in his name retain supreme power, under the name of ras (head or chief), until in turn unseated by a rival adopting the same course. In this way there have been as many as twelve puppet emperors at one time, representing the same number of rival chiefs. The country has in consequence been kept in a perpetual state of revolution. From its great natural features it must, however, be always divided into three leading parts: (1) Tigré, forming the northern promontory of the table-land, where the Geez, a Semitic dialect, is spoken, and through which passes the chief route to the Red sea; (2) Amhara, the middle province, where the language is the non-Semitic Amharic, and in which is Gondar, the capital and seat of supreme power; and (3) Shoa, a southern prolongation of the table-land, where the language is also Amharic, but which is isolated from the rest of the country by intruding tribes of Gallas, an alien race. Among the minor provinces, the chief are Lasta and Waag, Semen, Godjam, and Kuara. In the last century, Gooska, a Galla adventurer, entered Amhara, the central province, and, securing possession of the puppet emperor, assumed the title of ras, and fixed his family in power at Debra Tabor. He was succeeded by his son, and his grandson, ras Ali, who, within the last quarter of a century, confirmed the power of his family by successful military enterprises against the frontier tribes and the great chiefs, and by the marriage of his mother, Waizero Menin, a beautiful and clever woman, to Johannes, the nominal emperor. Such was the success of ras Ali that his supremacy was acknowledged by all the great chiefs except Dejaz Berro of Godjam, and that anarchy seemed about to cease for a time in Abyssinia. It was then for the first time that relations were opened between the central province and England. So early as 1810, while Great Britain was engaged in her struggle with Napoleon, Mr. Salt was sent as her envoy to Abyssinia; but he went no further than Tigré, the ras of which was treated as an independent sovereign. When the power of the French was destroyed in the eastern seas by the capture of the Mauritius, and the destruction of the French settlements in Madagascar, the English government ceased to take any interest in Abyssinia, and Mr. Salt was recalled. One member of the English mission, however, a Mr. Pearce, remained behind, and acquired the confidence of Dejaz Sahagadis, who, in 1816, on the death of Walda Selassie, acquired the government of Tigré. The favor manifested by the prince last named to Englishmen induced the church missionary society to establish a mission within his territories, with which was connected Dr. Gobat, since Anglican bishop of Jerusalem. Tigré was conquered, however, by Dejaz Oubie of Semen; and the missionaries, who remained faithful to the family of the displaced chiefs, were compelled to leave the country. An opening was thus made for the Roman Catholics. They seized the opportunity, and under padre de' Jacobis, a very able Neapolitan, established themselves in Tigré, and succeeded in making a strong impression on the population, among whom their leader became known as the abuna Yacob, and was invested with invested with some share of the veneration bestowed on the native abuna. In consequence of the large sum exacted by the Egyptian government on the consecration of an abuna, the office had remained vacant for many years. To secure the influence of the native church, however, Dejaz Oubie sent a mission to Egypt to obtain the appointment of a new abuna, and the padre de' Jacobis accompanied it, to secure, if possible, the selection of a priest favorable to Rome. He was, however, thwarted by the Coptic patriarch, who appointed Abba Salama, a young man partly educated in the English church mission at Cairo, and who was afterward to be mixed up with the fortunes of king Theodore. Shoa had also been brought into contact with Europe by a Protestant mission in 1838. Two years afterward the same country was visited by maj. Harris; but owing to deplorable jealousy, no permanent result followed. The first direct intercourse with Amhara, the central province, was brought about by Mr. John Bell, an officer of the Indian navy, who had married an Abyssinian, the daughter of a chief, and settled in the country. He had taken service in the army, in which he commanded the matchlockmen, and he had become the most trusted friend and adviser of ras Ali. He liked the country, and thought it could be opened to English commerce and colonization with incalculable advantage to both countries. In 1842 he was visited by Mr. Walter Plowden

a Calcutta merchant, on his way to Europe from India, to whom he communicated his schemes, and imparted his own enthusiasm. The two Englishmen became bosom friends, and remained together five years in Abyssinia. In 1847 Mr. Plowden proceeded to England to lay his views before the English government. He was less successful than he expected; but he convinced lord Palmerston that under ras Ali a central and permanent government had been established in Abyssinia, and that it was desirable to open commercial relations with the country. He was appointed consul, but unfortunately his head-quarters were fixed at Massowah, a sea-port within the Egyptian frontier, a choice which at once excited the suspicion and wounded the vanity of the Abyssinians. On Nov. 2, 1849, a treaty was entered into between ras Ali and Mr. Plowden, and there seemed every prospect of a close connection being established with this country, when all that had been done was rendered useless by the rise of Theodore, and the entire destruction of the power of ras Ali.

In the early part of the century, Kuara, a district of Amhara, s.w. of lake Tzana, was ruled by Dejjaj Comfu. The brother of this frontier chief died young, leaving a widow in great poverty, and a son born in 1820, named Kassai, afterward Theodore. She was compelled to seek refuge with her boy in Gondar. There she lived in great obscurity, earning her bread by selling *kosso*, a specific against tape worm. What her rank was is doubtful; and it is not known how far her son was justified in claiming for her descent from the family of the titular kings. Kassai was admitted to a monastery, where he spent many years; but his asylum was afterward attacked by an insurgent chief, and he escaped with difficulty to Kuara. He joined the army of his uncle, then fighting the Turks; and he distinguished himself so much by courage, intelligence, activity, and tact that he obtained a wonderful influence over his fellow-soldiers. Dejjaj Comfu died suddenly, and his three sons quarreled. To settle their dispute, Birru Goshu, chief of Godjam, was called in. He entered Kuara, and conquered the best part of it. Kassai, however, resisted him, and at the head of a numerous band of soldiers took refuge among the mountains. He was there attacked by Waizero Menin, the mother of ras Ali, who, as we have seen, had married the titular emperor Johannes, and who at that time ruled Dembea, the district near Gondar, the capital. Kassai encountered her troops, defeated them several times, and recovered possession of Kuara. Ras Ali thought it prudent to come to terms, recognized him as governor of Kuara, and gave him his daughter in marriage. This alliance did not, however, reconcile Kassai and Waizero Menin. They again quarreled, and again Kassai was victorious. He captured Waizero Menin, and compelled his father-in-law to acknowledge him as ras of Kuara and Dembea. Ras Ali had, however, become alarmed at the power of Kassai, and determined to crush him. As representing the ras, Birru Goshu attacked him with a powerful army, and compelled him again to seek refuge in the mountains of Kuara. In the following year, Kassai entered the field against Birru Goshu, conquered him, and slew him with his own hand. He then marched against ras Ali, and drove him to Debra Tabor, the old stronghold of his family. There he maintained for a time a determined resistance, but he was compelled at last to yield, and he then sought refuge in the country of the Gallas, where he died. Kassai then attacked the Dejjaj of Godjam, son of the chief he had killed, and defeated him. The whole of Amhara thus fell into his possession. Having secured the person of the titular emperor, he called upon Dejjaj Oubié of Tigré and Semen to pay tribute to him. This demand was refused with insult. Such, however, was the power of this chief that Kassai dreaded to attack him. The rivals met in Feb., 1854, and, to avert bloodshed, agreed to allow the magnates of the empire to decide which had the best right to the throne. The abuna was more under the control of Oubié than Kassai, and the latter felt that the weight of the church would be against him. Padre de' Jacobis, as already mentioned, had acquired considerable influence in Tigré. Theodore made advances to him, and offered that if he, as head of the Latin church, would support his cause, and crown him king, he would compel the people to adopt the Romish rites. Dr. Beke asserts that the padre de' Jacobis accepted the offer. Kassai marched against Oubié, and in Feb., 1855, a battle was fought at Debereskié, in which the latter was captured, as well as the abuna Salama. Kassai, unscrupulously disregarding his promise to the Roman Catholic prelate, now made advances to the abuna Abba Salama, and obtained his consent to acknowledge his descent from Solomon and the queen of Sheba, and to crown him emperor. The conditions exacted were that Kassai should support the Coptic church, and banish the Roman Catholics. A few days after the battle, Kassai was accordingly crowned by the abuna as Theodore of Abyssinia. It was not without reason that this name was chosen. According to an old tradition, a king Theodore was to reign in Abyssinia, conquer the kingdom of Solomon, and restore the ancient glory of Ethiopia. Kassai believed, or affected to believe, himself the man thus announced. He proclaimed himself a descendant of Solomon, but it does not appear that he ventured to ignore the titular king; on the contrary, since his coronation, he is represented as standing in the presence of the latter, naked to the waist, as is the custom of an Abyssinian servant in presence of his master. On the annexation of Tigré, Theodore resolved to attack Shoa, the third great province of the old empire. He invaded the country of the Wollo Gallas, defeated them, and reached Ankobar, the southern capital. The people were frightened by the sudden death of the king, and submitted without a struggle. Theodore now resolved to extend his conquests to the Red

sea, and enter on a crusade against the Turks for the recovery of the sea-board. He had treated up till this time the conquered provinces with great leniency, generally leaving one of the ruling family in power, and to Mr. Bell and Mr. Plowden he extended the same protection they had from ras Ali. He heartily adopted many of their schemes, and was anxious to open up intercourse with England. It was difficult, however, to negotiate with him. He believed himself to possess the same claim to respect as a European monarch, and was kept in perpetual torture by imaginary slights, and more especially by the respect shown to the Turks, whom he regards as barbarians. His vanity and touchiness were aggravated by reverses. The conquest of Shoa had not long been completed when the Dejaz of Godjam and the prince of Tigré rebelled, the latter being supported by the French. At the time when the Roman Catholic missionaries were banished by Theodore, Dr. Krapf and the rev. Martin Flad entered central Abyssinia to found a Protestant mission under the auspices of bishop Gobat of Jerusalem. They proposed to introduce handicraftsmen, not priests, who were to follow their usual avocations, and in addition, merely to read the Scriptures, and distribute copies in the natives languages. The scheme met with Theodore's approval. In April, 1856, the first member of the mission arrived, and others followed. Encouraged by their success, the rev. H. A. Stern afterward went to Abyssinia as agent of the society for promoting Christianity among the native Jews or Falashas, and obtained the consent of the king and abuna to found another mission. He went back to Europe, but returned early in 1863, accompanied by Mr. and Mrs. Rosenthal. A third, known as the Scotch mission, was founded, and all were well received. The first quarrels of Theodore were with the diplomatists. He was indignant at the proposal made by the English foreign office to exercise jurisdiction over criminals in Abyssinia, without granting him reciprocal rights. In Nov., 1855, he was still further irritated by our refusal to receive any embassy from him without an assurance that he was to renounce all idea of reconquering from Egypt the Abyssinian territory of which it had taken possession. At this period our government are accused of having systematically ignored complaints against the Turks. They certainly, without justification, expressed great dissatisfaction with the failure of Mr. Plowden to realize the advantages of intercourse with Abyssinia, although he, in a series of admirable papers, unfortunately not published at the time, proved that it had arisen from causes he could not have anticipated. Personally, Mr. Plowden remained on the best terms with Theodore, and if he had lived, all might have gone well. The consul, however, exposed himself to great risks. He was returning to Massowah from Gondar when he and a company of fellow-travelers were attacked by Garod, a rebel chief. He was wounded, and died of the injury he received. The king and Mr. Bell marched against Garod, and killed him. Garod's brother then killed Bell, and a horrible slaughter of the insurgents ensued. After the death of Mr. Plowden, capt. C. D. Cameron was appointed consul. Theodore was not consulted, and the new consul was coldly received in Oct., 1862. The Egyptians were at the time advancing within the northern frontier of Tigré, and Abyssinian Christians had been subjected to indignities at Jerusalem. Theodore resolved to appeal to the English and French governments, and wrote letters claiming their protection. That to the queen was forwarded to Aden; but unfortunately did not reach London until Feb., 1863, when it was thrust into a pigeon-hole and ignored or forgotten. In the meanwhile consul Cameron was directed to visit Sennaar, on the frontier of Egypt and Abyssinia, to judge of its fitness to become a cotton-producing country. The object of this journey was not explained to Theodore, and he naturally believed it to be a visit by a spy to his enemies the Turks. His suspicions were not allayed when the consul, on his return to Gondar, could produce no answer to the letter. He had received a dispatch, but it simply ordered him to go back to Massowah, and not to interfere with Abyssinian politics. "So your queen," said Theodore, "can give you orders to return to Massowah, but she cannot send a civil answer to my letter to her. You shall not leave till that answer comes;" and the consul was detailed on parole at Gondar. In reply to the French letter, M. Lejeau was sent to Abyssinia. A written answer to Theodore was read, in which, as if it had been intended to irritate him, something was said of the protection accorded by the emperor of the French to all Roman Catholics in the east. This aggravated the offense already committed by the French—that of aiding the prince of Tigré. The letter was torn and trampled upon, and M. Lejeau, imprisoned for a few days, was ordered off to Massowah. Theodore declared he would no longer be "humbly begged by missionaries and consuls like a rajah of Hindustan," and the European residents all felt that a crisis had come. In Oct., 1863, consul Cameron sent letters to Massowah. His messengers were stopped, deprived of their dispatches, and beaten. On the same day Mr. Stern, who happened to pay a visit of ceremony to the emperor, inadvertently gave him offense; and he and his two servants were ordered to be beaten. The servants died the same night. Mr. Stern himself was so seriously hurt that his life was despaired of. His papers were then examined and found to contain remarks derogatory to the emperor. He and Mr. Rosenthal were arrested, and on Nov. 20 they were publicly tried with all the formalities of Abyssinian law—on a charge of having committed the *crimen læsæ majestatis*. Mr. Stern was accused of having circulated the report in Europe of Theodore being the son of a beggar-woman who sold kosso, and of his not being the descendant of Solomon and the queen of Sheba; while Mr. Rosenthal was accused of having

said that the country would fare better under the Turks than Theodore. The prisoners were condemned to death, but the sentence was not carried out. Two days after the trial dispatches arrived for capt. Cameron, but there was no reply to Theodore's letter. Under these circumstances the consul was injudicious enough to apply for permission to leave. He was arrested and thrown into the prison at Gondar with the missionaries, where they remained till the following summer, when they were removed to Magdala. The English government did not seem to interest themselves about the consul; but the case of the missionaries was warmly taken up by lord Shaftesbury and the religious public. A letter of capt. Cameron's was published, in which he said, "No release until an answer is sent to the letter to the queen." The subject was brought before parliament, and the government were compelled to search for this document. It was found in the pigeon-hole where it had been put, indorsed by lord John Russell. It had been written in 1862; it was answered in June, 1864. The reply was intrusted to Mr. Hormuzd Rassam, a native of Mosul, who had been employed in diplomatic service at Aden. The choice of this envoy was most unfortunate—he being, in the eyes of Theodore, a mere Turk, and therefore a spy and an enemy. He was not received till Jan., 1866, and then a second error was committed. Mr. Rassam accepted a large present from Theodore, and did not, or was not enabled to repay it, as was expected, by a gift equal in value, although the necessity of doing so had been fully explained to the government. Theodore then sent the English envoy, who was treated as a mere beggar, to prison with the other captives. This was his first distinct breach of the law of nations. After this period, he conducted himself like a madman: he caused women and children to be tortured, dishonored, and starved in an unheard-of manner. "Out of 3,000,000 inhabitants," says Dr. Blanc in June, 1867, "he has destroyed more than a third by war, famine, and murder." After some unsuccessful attempts to negotiate with Theodore, through Mr. Flad, in the early part of 1867 lord Stanley in April, ordered him within three months to deliver up the prisoners. He took no notice of the communication, and accordingly an expedition was fitted out at Bombay for the invasion of the table-land. The force consisted of upward of 10,000 soldiers. Early in November the advanced brigade landed at Zulla, on the Red sea. From this point the expedition advanced successfully in spite of many difficulties, and, in the beginning of April, 1868, came within sight of Magdala. On April 10, near Magdala, Theodore gave battle to the British forces, and sustained a defeat so decided that he forthwith made submission to the extent of surrendering all the European captives in his power; and on the 13th, Magdala, into which he had retired, was stormed, and with little difficulty was taken possession of by our forces. Neither in the battle nor the assault was there any loss of life on the British side, only a few being wounded; the Abyssinians sustained a loss of 500 killed and 1500 wounded, the most notable among the former being Theodore himself, who was found dead, shot in the head.—See *The British Captives in Abyssinia*, and other works, by C. T. Beke, PH.D.; the government blue-books; an article in No. 65 of the *Westminster Review*, new series; the works of Harris, Rudolph, Lejean, and Dufton.

THEODORE, of Mopsuestia, a well-known writer of the Syrian church, and especially notable in connection with the controversy of "The Three Chapters," was born of a wealthy and distinguished family at Antioch, in the first half of the 4th century. He was the school-fellow and friend of St. John Chrysostom, and his fellow-pupil under the philosopher and rhetorician Libanius; and he was induced by the earnest exhortation of Chrysostom, to join with him in embracing the monastic life. His theological and scriptural studies were made under Flavian of Antioch and Diodorus of Tarsus; and having received priest's orders, he resided for a time at Antioch, where his learning and eloquence won the highest applause; and afterward at Tarsus, under his old teacher Diodorus. About the year 390, or a little later, he was chosen bishop of Mopsuestia in Cilicia. In 394 he preached in the presence of the emperor Theodosius at Constantinople, on occasion of a synod held in that city. Of his further history little is known; but his literary activity must have been prodigious, if we can judge by the contemporary accounts, and by the number of the works which are ascribed to him, but of which only fragments now remain. The most important of these consisted of commentaries on almost all the books of Scripture, and various polemical writings. A supposed tendency to Pelagian and Nestorian errors was observable in Theodore, and was in part the occasion of the long controversy of the three chapters. This controversy, however, did not arise till long after the death of Theodore, which took place about 427. Considerable fragments of Theodore's commentaries have been published by cardinal Mai in his *Spicilegium Romanum*, and some of his works still exist in Syriac; but by far the greater proportion has been lost.

THEODORETUS (Gr. *Theodoretos*, God-bestowed), a celebrated church historian and theological writer, was born at Antioch about the year 393, and received his name from the circumstance of his being supposed to have been granted as the fruit of earnest prayer, to his parents, who had long been childless. He was educated from early childhood in a monastery, where, among his fellow pupils, were Nestorius and John of Antioch, both afterward celebrated in the controversy which takes its name from the former. He was admitted among the clergy of Antioch; and at a comparatively early age became bishop of Cyrus, a city of Syria. His zeal and eloquence were the theme of

universal praise, and his success in bringing unbelievers and heretics to the church was almost unprecedented. In the controversies on the subject of Nestorius and his doctrines, which followed the condemnation pronounced by the council of Ephesus in 431, Theodoretus for a time took a warm and active interest. The party of Nestorius was with difficulty brought to an accommodation with Cyril of Alexandria, in virtue of which the condemnation of Nestorius by the council was acquiesced in by John, bishop of Antioch. For a time Theodoretus dissented from this condemnation of Nestorius; and he not only expressed these sentiments in a letter addressed to Nestorius himself, but also wrote formally against the celebrated anathemas of Cyril directed against Nestorianism. But he afterward saw the necessity of yielding, and concurred in the deposition of those bishops who still persisted in their rejection of the council of Ephesus. Nevertheless, he by no means fully accepted the views of Cyril; and when, on Cyril's death, the opposition to Nestorianism began to develop, under the turbulent partisanship of his successor in the see of Alexandria, Dioscorus, into the contrary error of Eutychianism, Theodoretus endeavored to induce Dioscorus to abandon his extreme opinions. Failing in the attempt, Theodoretus composed the work which has often figured in modern controversy, on account of the well known passage as to the change of the eucharistic elements which it contains, entitled "*Eranistes or the Many-shaped*." This work was regarded by Dioscorus as a renewal of the Nestorian error, and he accused Theodoretus to Dominus, the new patriarch of Antioch, of that heresy. Theodoretus replied with great moderation; but Dioscorus persisted; and having engaged the imperial court on his side, succeeded in obtaining from the emperor Theodosius II. an order confining Theodoretus within the limits of his own diocese. Meanwhile, the Eutychian controversy reached its height, and Eutyches (q.v.) having been first condemned by Flavian, bishop of Constantinople, in a synod held in 448, was afterward absolved in the celebrated robber-council of Ephesus, under Dioscorus in 449. The latter council not only excluded Theodoretus from its sittings, but formally deposed him from his see; whereupon he was compelled to retire to the monastery at Antioch in which he had received his first education. All this, however, was reversed by the general council of Chalcedon, in 451. Theodoretus did not very long survive his restoration. He died about the year 457. His works fill four volumes folio, reprinted in 10 parts 8vo, by Schulze (Halle, 1768-74), and consist of commentaries on many books of the Old Testament and the whole of St. Paul's Epistles; a *History of the Church*, from 325 to 429 A.D., in five books; *Religious History*, being the lives of the so-called fathers of the desert, a series of most curious and interesting pictures of early ascetic life; the *Eranistes*, a dialogue against Eutychianism; *A Concise History of Heresies*, together with orations and a large number of letters. Of these works, his *History of the Church* is by far the best known, as well as the most important and interesting. See Schulze's edition of *Theodoretii Cyrensis Opera*.

THEODORIC, surnamed **THE GREAT**, the founder of the Ostrogothic monarchy, which comprised Italy, Sicily, south-eastern Gaul, Rhætia, Noricum, Pannonia, and Dalmatia, was born on the banks of the Neusiedler See, to the s. of Vienna, in 455 A.D. His father, Theodemir, was one of the three brothers (the other two were Walamir and Widimir) who, on the death of Attila (453 A.D.), freed their nation from the yoke of the Huns, and being the representatives of the royal line of the Amali, exercised a united sovereignty over it; but the death of Walamir, and the departure to Italy and Gaul of Widimir with a part of the nation, left Theodoric's father sole ruler of the Ostrogoths who remained in Pannonia. Previous to these events, Theodoric had been given as a hostage to the eastern emperor, in accordance with whose directions he had been accustomed to all kinds of athletic and martial exercises, so that after his return (473) home, he was well qualified to fill the post of ruler of his ferocious and valiant kinsmen, which, by the death of his father, was left vacant in 475. In the previous year, the Ostrogoths had obtained parts of Mæsia and Dacia as settlements from the emperor Zeno, and for years they gallantly defended the empire from foreign aggressors, other Gothic tribes included; but the impolitic faithlessness of Zeno produced in revenge the devastation of Thessaly and Macedonia, and subsequently (487) a raid directed on the capital itself. The emperor, to free himself from his troublesome ally, gave him permission to invade Italy, a suggestion gladly adopted by the warlike monarch, who started for Italy in 488; and after forcing his way through the Gepidæ and others who attempted to bar his progress, and gathering recruits on the way, arrived in the summer of 489 on the frontiers of Italy. Odoacer was both forewarned and forearmed; and a desperate conflict between the two powerful armies took place near Aquileia (August 28, 489), distinctly to the advantage of the Ostrogoths. A second and more disastrous defeat was inflicted on Odoacer near Verona (Sept. 27), after which he took refuge in Ravenna; but having again gathered a large force, he was totally routed a third time on the banks of the Adda (August, 490), again blockaded in Ravenna, while the whole of Italy was being subdued; and having at last surrendered, was treacherously murdered (March, 493). Theodoric now assumed the title of *king of Italy*, resisted the claim of suzerainty preferred by the eastern emperor; and with the exception of a victorious campaign against the Franks, to compel them to cease their assaults on the Visigothic dominions, the suppression of a rebellion in Spain against the authority of the

infant monarch, his own grandson Amalric (during whose minority Theodoric administered also the government of the Visigothic kingdom), and an expedition against the robber hordes of the Bulgarians, the whole of his long reign was devoted to the consolidation and development of his new kingdom. His followers only received one-third of the conquered country; the rest was legally secured to the then possessors, and by degrees his barbarous followers were placed upon a footing of harmony with their fellow-subjects. Theodoric made Ravenna his capital; occasionally, when his northern frontier was threatened, removing to Verona. He died in 526. Theodoric holds the very highest rank among monarchs. An uneducated barbarian, and master of a power which even the most formidable of his neighbors, the Franks, could not have long withstood, he showed no desire of conquest; cultivated the friendship and esteem of the surrounding nations; ruled all classes of his subjects with irresistible authority, but with corresponding justice and moderation; zealously promoted agriculture and commerce till Italy again took its old position as the most prosperous country in Europe; and, himself an Arian, exhibited a tolerance of all other sects, which the latter, when their turn for supremacy came, were very far from imitating. The foul blot on his character is the judicial murder of Boëthius (q.v.) and Symmachus, for a supposed connivance with the senator Albinus to restore the authority of the eastern emperor in Italy; but every fact that can be gathered respecting this event bears out the belief that it was the result of a burst of passion, intensified by his extreme, nay, almost morbid, jealousy of Byzantine interference in Italy. The one great error of his administration consisted in his wholly neglecting to assimilate his Ostrogothic subjects with the previous inhabitants, either by a common code of laws, or by common official preferment; for though, under his sway, the evil of this separation did not appear, yet, when the scepter fell to weaker hands, an antagonism necessarily arose between the ruling and the subject races, which was the chief cause of the successful restoration of Byzantine authority in Italy by Belisarius (q.v.) and Narses (q.v.). Theodoric left no son; but his third daughter, Amalaswintha, succeeded him as regent for her son Athalaric; the eldest, Theodiscusa, having become queen of the Visigoths, and the mother of Amalric; and the second, Ostrogotha, the wife of Sigismund, the last king of the Burgundians.

THEODOSIA, or FEODOSIA. See KAFFA, *ante*.

THEODOSIUS, the name of three later Roman emperors.—**THEODOSIUS I.**, surnamed **THE GREAT**, and **THE ELDER**, to distinguish him from his grandson, was of Spanish descent, and was born either at Italica (as Gibbon and those who wish to make him of kin with Trajan maintain), or more probably at Cauca, near Segovia, about 346 A.D. His father, also named Theodosius, was the great general of the Roman empire, who, after freeing South Britain from the savage Caledonians, who roamed over it at their pleasure, and annihilating the formidable rebellion of the Moor Firmus, which threatened to divorce the African provinces from the empire, was conspired against by his many malicious enemies at court, and summarily beheaded at Carthage in 376. Theodosius, who had accompanied his father in his British campaigns, and afterward, by routing the Sarmatians, saved Mœsia from devastation, retired from active service after his father's murder, and occupied himself with the care of his patrimonial lands in Spain. But his many virtues and talents were not forgotten at court; and on the defeat and death of Valens (q.v.), his colleague, Gratianus (q.v.), feeling his inability to sustain alone the cares of empire, summoned Theodosius from his retirement, invested him with the imperial purple, and confided to him, Jan. 19, 379, the administration of Thrace, Dacia, Macedonia, Egypt, and the east, and especially the protection of the empire against the Goths. This last charge called for the full exercise of the new emperor's abilities, for the army at his command dared not face the Goths in the open field; and even when, after the death of their able leader, Fritigern, the Ostrogoths and Visigoths separated, each breaking up into several bands, Theodosius found it most prudent to sow jealousy and dissension among them by promises and bribes, and after a four years' so-called campaign, succeeded in pacifying the Visigoths, the Ostrogoths retreating toward Scythia. The latter returned in 386, their ranks swelled by Scythians, but were totally routed in attempting to pass the Danube, and the survivors were transported to Phrygia and Lydia. In 387, Theodosius undertook to restore to the throne of the western empire Valentinian II, (whose sister, Galla, he married), the brother of Gratian, who had been expelled by Maximus; and after a uniformly successful contest, the usurper was captured and put to death at Aquileia. In 392, the suspicious death of Valentinian, and the elevation of the puppet Eugenius by Arbogastes, the real ruler of the west, again summoned Theodosius to interfere; and after two years of preparation, his motley army of Byzantines, Goths, Alans, and Huns, aided by the treachery of some of Eugenius's generals, gained a complete victory over the Gauls and Germans, who chiefly constituted the army of the west; and the two portions of the Roman empire were again united under one ruler. The union, however, lasted only four months, owing to the death of Theodosius, Jan. 17, 395. Theodosius, though a professor of the orthodox Christian faith, was not baptized till 380, and his behavior after that period stamps him as one of the most cruel and vindictive persecutors who ever wore the purple. His arbitrary establishment of the Nicene faith over the whole empire, the deprivation of civil rights of all apostates from Christianity and of the Eunomians, the sentence of death on the
